Respect for persons comprises acknowledging and protecting the autonomy of all individuals, including individuals whose capacity to exercise autonomy is diminished because of disability, illness, circumstances that restrict liberty, or immaturity (HHS, 2016b). Researchers must ensure that the volunteers are participating freely in a study, without coercion and after receiving full disclosure about the study and the potential risks involved. *Beneficence* requires that researchers protect participants from physical injury, psychologic harm, economic insult, and exploitation during or as a result of the study. It also addresses the requirement that the study be conducted for the benefit of others. *Justice* requires the fair treatment of all participants, including the right of participants to expect their personal information to be maintained under strict confidentiality and the protection of participant anonymity. The Health Insurance Portability and Accountability Act (HIPAA) includes a Privacy Rule, which creates a national standard for the disclosure of private health information.

Legal practices related to research studies include following criminal, civil, and tort laws. Study volunteers have a legal right to full disclosure of the study's purpose, required procedures, length, expectations, risks, and possible benefits before consenting to participate. **Informed consent** includes the right to receive this information as well as the right of participants to withdraw from the study at any time. Participants must give informed consent, usually in written form, before the study begins (refer to the module on Legal Issues for further information).

Implications for Nursing Practice

The nursing profession includes both nurse clinicians and nurse researchers who are working to determine best evidence. Nursing clinical research is important to provide best evidence for EBP, to support nursing as a separate professional discipline, and to define current best practice standards of nursing care.

Providing Best Evidence for EBP

Best practices in nursing have continuously evolved as a result of research. In today's healthcare environment, it is especially crucial to participate in EBP. Practice based on the reasoning "we do it that way because we've always done it that way" is inadequate and fails to consider the research evidence supporting new and improved nursing practices. Integrating EBP is necessary to meet the current standards of high quality in nursing performance.

Supporting Nursing as a Professional Discipline

Simply stated, nurses want to be in control of nursing. Nursing history reflects its growth as a professional discipline and efforts to gain recognition as a profession in the eyes of the general public and in the eyes of members of the other healthcare professions.

The criteria for nursing to be recognized as a profession continue to evolve. They currently include the following:

1. Specialized education requirements
2. A body of well-defined knowledge and expertise
3. Conducting ongoing research

4. An orientation toward service to others
5. Following a code of ethics
6. Having autonomy as a profession
7. Professional organization (see the modules on Professional Behaviors and Accountability for additional information)

Note that the first two items in this list—specialized education requirements and a body of well-defined knowledge and expertise—both depend, in part, on nursing research.

Defining Current Best Practice Standards of Nursing Care

EBP supports changes in the responsibilities of nurses, including clinical decision making and clinical judgment, and the level and extent of nurses' accountability. Standards of nursing care are defined by the ANA, the National League for Nursing (NLN), and The Joint Commission (see the module on Accountability for more information about standards of nursing care). These organizations periodically update these standards to reflect current best evidence. Rights, responsibilities, and scopes of nursing practice are legally defined by state nurse practice acts from each state's Board of Nursing (see the modules on Professional Behaviors and Legal Issues for additional information).

In addition to the standards set by professional organizations and state boards, each healthcare facility sets performance expectations for nursing care in its policies and procedures, in accordance with the state's nursing scope of practice. To protect themselves from liability, nurses need to follow policies and procedures as written. When practice evidence supporting better patient outcomes is discovered, the nurse becomes an advocate of that best evidence. Each facility has a process to follow in suggesting changes in policies and procedures; it may be a quality improvement committee, a policies and procedures committee, or a nursing unit's chain of command. There is room for any change that benefits staff and patients, and it is incumbent on nurses, as professionals, to advocate for changes that benefit their patients.

Developing Evidence-Based Practice

EBP is a combination of the knowledge that is generated from the clinician's experience, the research evidence, and the preferences of the patient. Nurses must commit to expanding the implementation of EBP within the nursing profession. Through such efforts, nurses continue their quest for the provision of safe, effective, high-quality patient care.

Step 1: Develop a Clinical Question

Formulating the clinical question is the first step in engaging in EBP (see **Figure 45-3**). Clinical questions are generated in many ways but are usually encountered during patient care. A clinical question may be knowledge-based (a background question) or practice-based (a foreground question). The type of question developed helps determine how and where to search for an answer. **Background questions** are general questions that seek more information about a topic,

Figure 45-3 » The four steps in developing evidence-based practice funnel together to produce best nursing practice for safe, effective, high-quality patient care.

such as diseases or medications. These questions serve to fill gaps in knowledge about a specific topic and take the form “What is . . .” or “What does. . .” The following are examples of background questions:

- Who is at risk for hypoglycemia?
- What are the side effects of a specific diuretic?

Answers to these questions can be found in textbooks, medical dictionaries, drug handbooks, and other educational materials.

Foreground questions are narrower in focus and are about a specific clinical issue. They are useful for finding nursing interventions that improve patient outcomes; in other words, they identify useful information about direct patient care. The following are examples of foreground questions:

- How does using an incentive spirometer (or not using one) affect the length of stay for a surgical patient?
- How does using a cooling blanket compare to using antipyretic medication as treatment for a patient with a high temperature?

Answers to these questions can be found in the studies conducted to elicit evidence. Types of research studies include the following:

- **Meta-analysis.** A group of studies on a given topic are examined, and their results are combined and analyzed as if they were from one large study.
- **Case study.** A case study is specific to one individual, issue, or event.
- **Cohort study.** A longitudinal study follows two groups and measures the outcomes of an exposure group with those of a nonexposure group.

TABLE 45–1 PICOT

PICOT	Definition	Factors to Consider	Examples
P opulation or P roblem of interest	What is the common factor in the group of patients? Alternatively, what is the problem that will be addressed?	Characteristic(s) common to patients in the group.	A specific age, gender, health problem, or medication taken by all group members
I ntervention	What will be done to the patients?	Activity shows the difference in the patient before and after the intervention.	A treatment, medication, therapy, test, or new routine of care
C omparison group or comparing interventions	What is the difference (alternative) in the intervention being used when comparing two groups?	<ol style="list-style-type: none"> 1. Can contrast an experimental group that receives an intervention with a control group that does not receive the intervention. 2. Can contrast an experimental group that receives the intervention of interest with a comparison group that receives a different intervention. 3. Can help establish a relationship, or the lack of a relationship, between an intervention and a predicted outcome. 	<ol style="list-style-type: none"> 1. Comparing two ways of doing something to find the best way. 2. Identifying the effect of taking medication A by comparing one group receiving medication A with a group receiving a placebo.
O utcome or desired effects	<ol style="list-style-type: none"> 1. In response to the intervention, what is the desired effect for the patient? 2. In relationship to a selected problem, what is the desired improvement? 	<ol style="list-style-type: none"> 1. Desired effects of an intervention can be proved or disproved. 2. Improved outcomes can result from an intervention. 	<ol style="list-style-type: none"> 1. The desired effect is to minimize or eliminate a specific symptom. 2. An improved outcome is to reduce the time needed to accomplish a task.
T ime frame (optional)	<ol style="list-style-type: none"> 1. How long will the study last? 2. How long will it take to achieve the desired outcome? 	Extent of time needed to study the impact of an intervention on a group may be brief or extended.	<ol style="list-style-type: none"> 1. A brief time could be the first 12 hours after taking a medication. 2. An extended time could be 6 months following a treatment regimen.

- **Case-control study.** Individuals with and without a specific condition are compared to identify predictive variables.
- **Randomized controlled trial (RCT).** This is the strongest type of study in terms of validity. RCTs are designed to illustrate a cause-and-effect relationship by using a control group (participants who do not receive an intervention) and an experimental group (participants who do receive an intervention) (Duke University Medical Center Library, 2016).

Another consideration is determining the type of question that is of interest. This information helps to further narrow the clinical question. Types of questions are as follows:

- **Diagnosis.** How to select and interpret diagnostic tests; accuracy, safety, cost effectiveness
- **Therapy.** How to select treatments that do more good than harm to patients and lead to the best outcomes
- **Etiology.** How to identify causes of a condition or disease

- **Prognosis.** How to predict a clinical course over time and possible complications related to a condition or disease process.

Clinicians commonly use the mnemonic PICOT (or, alternatively, PICO) to define and formulate a clinical question that will contribute to EBP. **PICOT** represents the elements of a clinical question (Nieswiadomy, 2012; University of Wisconsin–Madison, 2016):

- P**opulation (of patients) or **P**roblem of interest
- I**ntervention, prognostic factor, or type of exposure
- C**omparison of interventions or main alternative to the intervention (including no intervention)
- O**utcome (desired effect)
- T**ime frame (optional)

Both research studies and EBP projects use PICOT questions. PICOT develops foreground questions that apply EBP to clinical situations and problems (Table 45–1 >>).

Table 45–2 >> shows an example of the following clinical question in PICOT format: Among postoperative orthopedic patients, does hourly rounding increase patient satisfaction ratings related to nursing care?

TABLE 45–2 Example of Clinical Question in PICOT Format

Population	Intervention	Comparison	Outcome	Time
Postoperative orthopedic patients	Scheduled hourly rounding on a selected group of patients	No intervention/ patients who are not subject to the hourly rounding protocol	Increased patient satisfaction ratings	Four weeks of implementation and data collection

Case Study » Part 1

Brent Calloway is the new nurse educator for a local hospital's medical-surgical unit. During the past few months, he has observed a high number of incident reports related to nursing procedures. He wonders whether there is something he can do to lower this number and improve patient safety in the unit. One of his responsibilities is to organize a continuing education program for the annual review of competencies for the nurses. In past years, the nurses have had a mandatory meeting annually in which competencies were presented and demonstrated by the nurse educator while the nurses sat and watched. Brent is curious whether there is another, better approach to emphasize patient safety when the nurses review knowledge and skills for patient care.

Brent is aware that the staff development department uses computer technology for simulation scenarios during orientation for new nurses, and he wonders whether he could use that learning approach for continuing education programs in his division. He has helped with simulations in past employment and thinks that using this teaching strategy could support better patient safety. He questions whether changing the method of training could decrease the number of safety reports and improve patient outcomes.

Brent formulates the following PICOT elements:

P: Nursing staff

I: Simulation-based safety education

C: No intervention

O: Decreased incidence of procedural errors

T: 12 weeks for implementation of intervention and data collection

On the basis of the identified PICOT elements, Brent formulates the following clinical question: "Among nursing staff, what is the effect of simulation-based safety education on the incidence of procedural errors?"

Before developing the EBP project, Brent plans to search for current research evidence related to the use of simulation-based education to promote safe nursing practice.

Clinical Reasoning Questions Level I

1. How does an EBP project differ from a research study? How would Brent's project development change if he were planning a research study instead of an EBP project?
2. What role did Brent's experience with computer-based simulation play in development of his clinical question?
3. Using the same PICOT elements, what are some other potential versions of the clinical question?
4. In Brent's clinical question, why is the target population stated as "nursing staff" instead of "medical-surgical patients"?

Clinical Reasoning Questions Level II

5. How important is it for Brent to have the support of his manager to be motivated to explore the potential of finding a better method of providing continuing education?
6. What is the value of nurses being inquisitive about the way things are done in their nursing practice?
7. Refer to the exemplar on Competence in the module on Accountability: What role does experiential learning play in the development of clinical expertise for nurses?

TABLE 45-3 Order of Sections Typically Found in a Professional Research Article

Section	Function
Title	Gives the main topic of the research study.
Abstract	Provides a summary of the entire content of the journal article.
Introduction	Presents the question, or focus, of the investigative study; includes background of older research on same hypothesis.
Methods	Describes in detail all the aspects and methods of the study.
Results of study	Reports statistical data; may be in the form of charts or tables.
Conclusion	Summarizes and interprets the results of the study and statistical data in relation to the hypothesis; evaluates the findings of the study.
References	Lists the resources available for additional information.

summary of the article; an overview of the study conducted, including its methodology; a written conclusion based on the results of the study; and relevant references. The order of sections typically found in a professional research article is shown in **Table 45-3** ».

Nursing databases and resource links can yield a list of evidence articles related to the question at hand (**Table 45-4** »). Many databases have a tutorial available. Some databases offer only abstracts; others offer the full text of the article. All sources and sites should be judged on their degree of credibility. Research resources can be found in various ways. One is to use a review-of-literature article that presents studies relative to a topic and ends with an evaluative statement, or recommendation, regarding the studies described. Another way is to use a primary resource, which is the original published article. Secondary resources, when

Step 2: Retrieve the Evidence

Looking for clinical evidence from research sources usually includes a review of the pertinent literature. When doing a literature review for evidence, nurses look for scientific elements in the journal article, including the abstract, or

one author is writing about the original work of another author, can also be helpful. Focusing on the most recently published materials can help narrow the number of evidence resources.

The nurse who has difficulty accessing electronic databases from work or home should make use of local reference librarians and other available resources. Many libraries, particularly at colleges and universities, have access to nursing journals both online and in print (**Box 45–4** »). The nurse who cannot get support from employers and colleagues may want to do more networking with local chapters of professional organizations such as the ANA.

The Agency for Healthcare Research and Quality (AHRQ) funds 13 Evidence-Based Practice Centers (EPCs). Through their efforts, these centers improve the quality and effectiveness of healthcare by reviewing all relevant scientific literature, synthesizing the evidence, and helping to translate the evidence-based research findings so they are more readily available to clinicians who are at the bedside providing care (AHRQ, 2015).

» **Stay Current:** For more information on the 13 Evidence-Based Practice Centers, go to <http://www.ahrq.gov/research/findings/evidence-based-reports/overview/index.html>

Case Study » Part 2

Recently, Brent Calloway read an article in his staff development journal about a research study that suggested that the use of simulation enhanced nursing competence and benefited patient safety. He wonders whether his unit could experience similar results. In the article, the nurses participating in the study reported high levels of satisfaction related to the use of simulation in a safety-controlled environment to support their learning. The results of the study also suggested that the incidence of nursing errors decreased by 30% following several sessions of simulation training.

By searching multiple databases, Brent finds several current, peer-reviewed resources, including research studies that suggest that

Focus on Diversity and Culture

Pharmacology and Genetics

Two fields of study in particular—pharmacogenetics and pharmacogenomics—represent an intersection of research, genetics, and pharmacology (U.S. National Library of Medicine, Genetics Home Reference [GHR], 2016). Pharmacogenetics emphasizes application of the research process to study the genetic basis for unexpected drug responses demonstrated by individuals (Patil, 2015). Inherited differences, particularly those related to ethnicity and race, are key considerations to pharmacogenetics researchers. For example, pharmacogenetics is used to investigate why beta-1 blocker medications have limited efficacy when used to treat congestive heart failure among some individuals who are of African American heritage (Ortega & Meyers, 2014).

By comparison, pharmacogenomics takes a broader approach to exploring the link between genetics and pharmacology. By combining pharmacology with the study of genes and their functions (GHR, 2016), pharmacogenomics focuses on examining a multitude of genes that may influence the pharmacologic response (Patil, 2015). Both pharmacogenetics and pharmacogenomics have important implications for the development of medications that will more effectively treat health problems among a culturally diverse population.

there is a correlation between simulation-based safety training and a decreased incidence of nursing-related errors in patient care. Brent is excited about exploring the impact of implementing simulation-based education to improve nursing practice in his unit and, ultimately, to promote patient safety and improve patient outcomes.

Clinical Reasoning Questions Level I

1. Which search terms would be appropriate for Brent to use when searching an online database for scholarly resources related to his topic?
2. When seeking current scholarly resources, what limits should Brent place on the publication dates?

Clinical Reasoning Questions Level II

3. What are peer-reviewed resources? What is the rationale for Brent's inclusion of only peer-reviewed resources in the research review?
4. If Brent decided to search authoritative websites for information, what criteria would be most appropriate for use in the selection of the authoritative websites?

Step 3: Evaluate the Evidence

Evidence that is gathered must be critically appraised for validity (the degree to which the study measured what it intended to measure), reliability (the ability to produce consistent results with each use), and usefulness in applying the evidence in clinical practice. Nurses must be able to critique research articles to identify the strengths and weaknesses of the studies and their resulting evidence. By doing this, nurses can discard materials that do not meet the standards for application in patient care. Appraising clinical significance answers the question “Is the comparison difference significant enough to change nursing practice?” In other words, does the study yield

Hierarchy of Research						
Least powerful evidence	Somewhat stronger evidence	More compelling evidence comes from research studies				Gold standard
Opinions of reviewers that are based on their experience and knowledge	Opinions that come from well-known experts and respected authorities	Non-experimental studies: correlational, descriptive, qualitative	Quasi-experimental studies: time series, matched case-controls	Individual experimental studies	Meta-analysis of controlled studies	Large randomized controlled studies and meta-analyses of controlled studies

Figure 45-4 » Hierarchy of research.

information that is reliable and useful enough to warrant a change in practice? Unfortunately, it is sometimes difficult to know which evidence yields best nursing practice patient care.

Measure the significance of the information gathered by rating the strength of the evidence to determine its validity and its relevance to a given clinical situation (Oncology Nursing Society, 2012). Rating the strength of evidence helps to identify best choices to support greater effectiveness and positive outcomes in specific clinical situations. To categorize scientific data, various companies and organizations use different methods to illustrate the hierarchy or levels of evidence. Assigning levels of evidence can help nurses identify the strongest evidence available for use as best practice. There is general agreement that the highest level of research (research that is considered the most reliable and valid) includes large randomized controlled studies and meta-analyses of controlled studies (**Figure 45-4** »). Following this hierarchy, nurses can rate evidence strengths, compare the results, choose the strongest ones, and apply them to patient care for best results.

Many professional nursing organizations have developed guidelines to provide their members with evidence-based information they can use in the caring interventions of their nursing specialty. For example, the Institute for Emergency Nursing Research (IENR), which was launched by the Emergency Nurses Association (ENA, n.d.a), publishes Clinical Practice Guidelines (CPGs). Based on a comprehensive literature review and analysis, CPGs rate the strength of evidence and provide recommendation levels for practice: high, moderate, weak, and not recommended for practice (ENA, n.d.b).

Another example of rating the strength of evidence is called Putting Evidence into Practice (PEP) used by the Oncology Nursing Society. PEP helps identify and qualify evidence-based interventions for patient care and teaching. The stoplight is used as an analogy to demonstrate the following categories of evidence strength:

Green light: Strong evidence supports interventions that are likely to be effective and helpful.

Yellow light: Not enough evidence is available to determine the effectiveness of the interventions as harmful or helpful.

Red light: Strong evidence indicates that interventions are likely to be ineffective or possibly harmful (Oncology Nursing Society, 2012).

As nursing clinical research grows, so too does the amount of new published materials on nursing. Strategies that nurses can use to stay abreast of current information include participating in research committees, continuing education programs, and listservs or newsletters. Participation with other nurses in a research or journal club is an excellent way to maximize critical evaluation of current articles related to specific interests.

Case Study » Part 3

When Brent Calloway discussed with the vice president of his division the use of evidence to make decisions about changing training methods to improve patient safety, she agreed that it was a good idea and was very excited about it. Brent has organized a team to help him explore the topic of using simulation for experiential learning, which could positively affect patient safety outcomes. The team includes a nurse from the staff development department who is familiar with using simulation training; two staff nurses and one nurse manager from the medical-surgical division, who would be directly affected by any changes that might be implemented; and a nurse from the quality improvement division, who has experience in developing EBP.

At the first meeting, Brent explains the group's objective. He gives each member a copy of the journal article he had previously read, and he discusses his plan for the medical-surgical division. The group members decide on a course of action after discussing several possible ways to proceed. They decide to use the PICOT question Brent developed. Members of the team are asked to do a literature search for research evidence, critically appraise the evidence they find, and bring the highest-rated evidence to the next meeting for further evaluation by the team. The team will then evaluate the EBP outcomes and decide whether to change the current practice based on any new evidence found. Everyone is very enthusiastic, and they want to do all they can to help with this project.

Clinical Reasoning Questions Level I

1. Why would careful selection of members for this project team be important for the success of the project?
2. How would each team member evaluate the research evidence?
3. In the context of research findings, what is the difference between reliability and validity?

Clinical Reasoning Questions Level II

4. What other participants might Brent have asked to be on the project team to help during this EBP process?
5. What is the value of having all team members achieve consensus regarding the clinical question?

Step 4: Apply the Evidence

Once the evidence related to the clinical question has been collected and evaluated, the nurse is ready to integrate the best evidence with the nurse's own clinical experience and the patient's personal preferences. But that process in itself is not sufficient; once the nurse (or division or healthcare team) implements the change in practice, the change needs to be evaluated for its impact on patient outcomes. This process begins at implementation, with monitoring the process to make sure the change is replicated as intended. Is it being done correctly? Does it yield the intended results? Were there any unexpected results? What areas need improvement? The nurse analyzes the data collected and decides to accept, reject, or modify the change for clinical practice. If the change shows benefits to the patient, the facility, through committee work, can choose to modify policies and procedures to reflect the new practice. The change then becomes a part of the nursing routine until it is fully integrated into the standards of care.

Individual nurses can follow this process to identify the best evidence for specific clinical questions they may have about delivering care to patients assigned to them. They can evaluate and change their routines of care to maximize positive patient outcomes, such as reducing the length of stay or promoting cost effectiveness. However, the EBP process does not end with the individual nurse. After evaluation and satisfaction with patient outcomes, nurses should expand the "EBP loop" by sharing the findings with other colleagues. The results can be disseminated in a variety of ways, both informally at the agency level and, more important, formally through presentations at national conferences and by submission of articles for publication in professional journals.

Many medical facilities and professional organizations are providing more support for EBP and the dissemination of best evidence patient care outcomes. An evidence committee may be available to facilitate the evaluation of evidence. Pilot trials may be used on one nursing unit and then rolled out to the whole facility.

If this development process sounds familiar, it is probably because the steps are very similar to those of the nursing process of assessment, diagnosis, planning, implementing, and evaluation. Where the nursing process seeks to address the patient's holistic needs, the process of EBP deals with a specific clinical question that may be researched in an attempt to improve patient outcomes related to the clinical question.

The explosion of informatics in healthcare has also generated a need for a common language that individuals can use to access and share information. This common language allows nurses to code information to track nursing care processes and revise as necessary. Information technology involves more than providing or improving access to information; it also involves developing new ways for

nurses to share information on best practice. Listservs, social media groups, blogs, and videoconferencing are just a few of the ways in which information may be shared through technology.

EBP is a continuing process because new evidence replaces older evidence; healthcare is not a static system; and over time, nurses advance their clinical expertise. What is known today may be changed tomorrow as science progresses. EBP gives a framework and set of tools that nurses can use systematically to improve as clinicians, using the best of its three components: patient preferences, clinical nursing experience, and current evidence (see Figure 45–3).

Case Study » Part 4

Evidence found by Brent Calloway's group demonstrated that simulation was an effective method of learning for nurses, as shown by several study outcomes brought before the group for discussion. The study outcomes the group included:

- Decreased time required to implement interventions
- Improved organization and completion of simulated tasks
- Improved infection control
- Improved communication skills that supported quick, efficient actions
- Increasing ability of nurses to anticipate needed patient interventions

These results were very exciting to the team and reinforced the value of how changes in the delivery of continuing education can achieve a positive impact on patient safety.

After reflecting on all the evidence, the group decided on an educational plan for the nurses using a simulation teaching strategy. The medical-surgical division would be able to use the simulation unit in staff development for nurse competence. The two nurses and nurse manager would answer questions from nursing staff and would serve as the division champions for simulation. The nurse with additional training in EBP would continue to serve as a resource to staff.

In addition, Brent developed a schedule to visit all units in the division to discuss simulation, and the group posted flyers in the staff break rooms about simulation. The vice-president of the medical-surgical division remained supportive of this EBP change process.

Two months after the first nurse competence simulation training was completed, Brent and the team reviewed safety reports related to nursing procedures. Initial results showed a 73% reduction in the number of safety problems. The nurses in the division reported an increased awareness of safety for patients because of the hands-on simulation training they had received. An increase in patient safety was demonstrated that supported better patient outcomes. As a result, other divisions in the hospital are interested in hearing more information about how the EBP change could enhance learning outcomes and positively affect patient safety in their divisions. A potential rollout for the whole hospital is on the agenda for discussion at the next quarterly management meeting.

Clinical Reasoning Questions Level I

1. Why was work done in advance to let the nurses know of an upcoming change in how things were being done?
2. What steps did Brent's team use to develop and implement the changes they sought?
3. Who ultimately benefited most from the EBP change in training? How?

Clinical Reasoning Questions Level II

4. For the EBP change in training to be successful, how important is "buy-in" from the nurses? From management? From the facility, as a whole, to support a general culture of EBP?

5. How could the project team integrate best evidence with nursing expertise and patient preferences in changing to an EBP method of training for the nurses?
6. In addition to improved patient safety outcomes, what benefits might result from implementation of EBP in this situation for the nurses? The facility?

Lifespan Considerations

Without exception, nurses must work within their scope of practice and adhere to federal, state, and local laws that govern their practice. Similarly, all patient care should be reflective of EBP. Although nursing care is tailored for individual patients according to a multitude of factors (for example, the patient's health, weight, age, allergies, culture, and personal preferences), the degree to which nursing practice is based on evidence should not vary. Any intervention either is based on current evidence or is not.

Healthy People 2020 provides an excellent source of national health objectives, which serve to highlight areas in which EBP is needed as well as the availability of evidence-based resources. The following sections provide an overview of selected *Healthy People 2020* objectives and resources related to caring for individuals throughout the lifespan.

Evidence-Based Practice in Care of Infants

Healthy People 2020 (HHS, 2016c) objectives include reducing the rate of fetal, neonatal, and infant deaths, including deaths resulting from birth defects and sudden unexpected infant deaths (SUIDs). Evidence-based resources related to newborns and infants address topics such as screening protocols for phenylketonuria and sickle cell disease (HHS, 2016d).

Evidence-Based Practice in Care of Children

Healthy People 2020 objectives include reducing child mortality rates as well as decreasing the incidence of transmission of preventable diseases among children. Increasing access to a *medical home*—which is a model of care that promotes physician-led, patient-centered, coordinated health services—for children with special needs is also an objective (HHS, 2016c). Evidence-based resources related to the care of children address topics including vaccination programs, obesity prevention, and screening for visual impairment among children between the ages of 1 and 5 years (HHS, 2016d).

Evidence-Based Practice in Care of Adolescents

For adolescents, *Healthy People 2020* objectives include reducing the mortality rate among this population as well as increasing the proportion of adolescents with special health-care needs who receive patient care within a comprehensive, coordinated, family-centered system (HHS, 2016c). Evidence-based resources related to adolescent care address topics including vaccination programs, obesity prevention, and reduction of secondhand smoke exposure (HHS, 2016d).

Evidence-Based Practice in Care of Pregnant Women

For pregnant women, *Healthy People 2020* objectives include reducing mortality rates among this population, reducing the rate of pregnancy-related complications, and reducing the occurrence of cesarean births among women who are at low risk for complications (HHS, 2016c). Evidence-based resources address topics including preventing excessive alcohol consumption among pregnant women, educating mothers about breastfeeding, and screening for illnesses such as hepatitis B and bacterial vaginosis (HHS, 2016d).

Evidence-Based Practice in Care of Adults

Healthy People 2020 objectives address numerous issues related to the care of adults, including genomics and global health (HHS, 2016a). Targeting health promotion from a genomic standpoint allows for more accurate risk prediction, diagnosis, and treatment of a variety of health alterations, such as heart disease, stroke, cancer, diabetes, and Alzheimer disease (HHS, 2016e). Goals associated with the promotion of global health include protecting the health of the national population as well as limiting the international transmission of infectious diseases during travel (HHS, 2016f). Evidence-based resources related to global health and genomics are emerging.

Evidence-Based Practice in Care of Older Adults

For older adults, *Healthy People 2020* objectives address topics including increasing the number of individuals who are up to date on basic preventive care and decreasing the incidence of health alterations such as pressure ulcers and fall-related injuries (HHS, 2016e). Evidence-based resources discuss topics including screening for illnesses such as breast cancer and colorectal cancer (HHS, 2016f).

Strategies to Implement Evidence-Based Practice

Some basic activities can provide a foundation for implementing EBP. These strategies can spark the necessary stimulus to engage in behaviors that encourage best practice. Participating in EBP contributes to the knowledge of nursing and patient care in today's healthcare systems and delivery of high-quality nursing care for best outcomes.

- Assess yourself to determine how much of your current nursing practice is evidence-based. Make a list of actions you do in a clinical day. Beside each action, make a note whether it is evidence-based, the routine everyone follows, or a shortcut or whether you perform the action that way because that is how you learned it.
- Assess the obstacles that inhibit you from using EBP more frequently. These may include internal factors, such as beliefs or misconceptions, or external factors, such as lack of management support (**Box 45-5** »).
- Practice raising questions about current clinical practices and problem solving.

- Acquire more information to correct your misperceptions of EBP.
- If you only have limited time, focus on evidence from high-yield sources—those that are current, are known for their high quality, and have content applicable to patient care.
- Go to www.guideline.gov (AHRQ) for free resource compilations of evidence reviews and practice guidelines published by a variety of groups on a wide range of topics, such as hearing screening, learning disorders, screening, treatment, and prognosis.
- Use the internet when doing searches to cut down the time needed to find good evidence choices.
- Learn how to do a critical appraisal of evidence to determine the best evidence.
- Build your awareness of how and why things are done to identify how much EBP is being used.
- Identify others interested in searching for evidence and evaluating it for collaborative opportunities such as a journal club.
- Volunteer to participate on a professional nursing practice committee.
- Participate in a research project to be a part of an EBP process.

» **Stay Current:** AHRQ sponsors evidence reports and technology assessments through systematic reviews for health literacy interventions and outcomes from their Evidence-Based Practice Centers. Search for reports of interest to you at <http://www.ahrq.gov/research/findings/evidence-based-reports/search.html>.

Box 45–5

Barriers to Evidence-Based Practice

A barrier is anything that makes it difficult to progress or succeed in achieving an objective. Even though EBP can provide nurses with the satisfaction of knowing that they have given best evidence-based care to their patients to promote high positive outcomes, some typical barriers challenge nurses in implementing EBP in their daily practice. Some common barriers nurses confront in using EBP are the following:

- Work schedule and workload demands
- Patient preferences that might conflict with best practice care
- Lack of access to technology to find evidence when needed
- Limited knowledge in skills for finding and evaluating evidence
- Lack of experience and confidence in developing strategies to promote evidence-based care
- Lack of support from supervisors or agency personnel
- Lack of access to continuing education programs (e.g., due to lack of time, lack of funding, distance from program site)
- Attitudes of individual nurses (including lack of confidence in using EBP, misperceptions about EBP, lack of motivation in integrating EBP into routines of patient care, and failure to understand the value of EBP)
- Resistance to change from traditional patient care routines.

By learning the skills of EBP and gaining confidence in it, nurses are in the best position to overcome such barriers.

REVIEW The Concept of Evidence-Based Practice

RELATE Link the Concepts

Linking the concept of evidence-based practice with the concept of cellular regulation:

1. While caring for a pediatric patient with severe stomatitis secondary to chemotherapy, the nurse is concerned because the patient's mouth ulcers are not responding to current treatment. How can the nurse ensure that he is using current EBP?
2. The nurse learns of a new treatment that has had great results with treatment-resistant stomatitis. What should the nurse do next?

Linking the concept of evidence-based practice with the concept of advocacy:

3. How can the nurse best advocate for a patient who is considering becoming a participant in a clinical trial?
4. The nurse is caring for a patient who is involved in a clinical research study. The patient says to the nurse, "I don't want to be a part of this study any longer. How do I get out of it?" What would be the nurse's therapeutic response to this patient?

- Additional review materials

REFLECT Apply Your Knowledge

You are caring for a patient with severe persistent asthma who requires daily doses of inhaled corticosteroids, with frequent use of oral steroids during periods of exacerbation. The patient has been invited to join a research study to determine the effects of a new medication for patients with severe persistent asthma. The lead researcher has provided the patient with the necessary information for informed consent. The patient has asked for time to think about it and discuss it with his spouse. When you enter the room, the patient asks, "What if I agree to participate and the medication doesn't work? Will that mean my asthma will get worse? Does that increase my chances of dying from an asthma attack?"

1. How can you best respond to the patient's questions?
2. How can you best advocate for this patient?
3. What are your ethical obligations to help this patient?

Module 46

Healthcare Systems

Module Outline and Learning Outcomes

The Concept of Healthcare Systems

Types of Healthcare Services and Settings

46.1 Differentiate the three levels of preventive healthcare systems.

Factors Affecting Delivery of Healthcare

46.2 Outline the factors affecting delivery of healthcare.

Frameworks for Providing Care

46.3 Differentiate the three common models of healthcare.

Access to Healthcare

46.4 Outline the factors that limit access to healthcare.

Nursing Care Delivery Systems

46.5 Differentiate the three models of nursing care delivery most frequently used.

Concepts Related to Healthcare Systems

46.6 Outline the relationship between healthcare systems and other concepts.

Resource Allocation

46.7 Explain the issues with allocation of resources and the nurse's role in decision making.

Healthcare Systems Exemplar

Exemplar 46.A Emergency Preparedness

46.A Analyze emergency preparedness as it relates to healthcare systems.

>> The Concept of Healthcare Systems

Concept Key Terms

Case management, 2778	Managed care, 2778	Primary prevention, 2775	Team nursing, 2782	Uninsured, 2779

Health literacy, 2778	Primary nursing, 2782	Secondary prevention, 2775	Underinsured, 2779	
Health promotion, 2776				

The concept of healthcare systems relates to the methods of healthcare delivery and management, including financing and coordination of services. Particularly in the past two decades, new cost-containment strategies and advances in technology—both informatics and medical technology—have combined to significantly change healthcare systems in the United States.

Nurses must have a solid understanding of the different types of healthcare settings and frameworks used to provide care. Some agencies use a combination of models, and each agency has its own specific policies and procedures. Nurses must understand that the concept of healthcare systems impacts all other concepts. Nurses must know the requirements of the agency in which they practice.

In addition, nurses must understand the barriers patients face to accessing healthcare, the issues they themselves face when resources are insufficient to meet patients' needs, and

their agency's and community's expectations for them when a disaster occurs.

Types of Healthcare Services and Settings

Healthcare delivery can be classified by the type of services offered. Today's healthcare systems tend to be oriented toward prevention. A **primary prevention** service focuses on health promotion and illness prevention. **Secondary prevention** services include the diagnosis and treatment of disease. **Tertiary prevention** consists of the restoration of health following an illness or accident and includes rehabilitation and palliative services.

Primary Prevention

Primary prevention attempts to avoid development of disease as much as possible and promotes healthy living. Until

the 1980s, healthcare was actually illness/disease care. Individuals typically accessed the healthcare system only when confronted with an illness or accident. The 1979 Surgeon General's Report from the federal government's *Healthy People* program laid the foundation for a national prevention agenda. Since 1979, *Healthy People* has set and monitored national health objectives to meet a broad range of health needs, encouraged collaborations across communities and sectors, guided individuals toward making informed health decisions, and measured the impact of prevention activities. *Healthy People 2020* sets a number of goals and identifies a number of leading health indicators (discussed in the module on Health, Wellness, Illness, and Injury), which, if addressed, should result in an increase in the quality and length of life and the eradication of health disparities.

Healthy People 2020 includes new initiatives that address health issues that came to the forefront of healthcare in the previous 10 years, such as dementias (including Alzheimer disease); healthcare-associated infections; early and middle childhood health; and lesbian, gay, bisexual, and transgender health (Office of Disease Prevention and Health Promotion [ODPHP], 2017a). Work has begun collecting data for *Healthy People 2030*, and the Office of Disease Prevention and Health Promotion seeks public feedback on their efforts (ODPHP, 2017b).

» **Stay Current:** For the full list of *Healthy People 2020* topics and objectives, visit www.healthypeople.gov/2020/topicsobjectives2020/default.aspx. To keep abreast of or even participate in the development of the *Healthy People 2030*, you can subscribe to the Healthy People listserv, and follow @GoHealthyPeople on Twitter.

Health promotion is another tool used to improve individuals' health. The World Health Organization (1998) defines **health promotion** as the process of enabling people to increase control over and to improve their health. While the primary purpose of health promotion is to improve an individual's quality of life, there are additional benefits. For example, preventing disease and using health promotion techniques to improve health are more cost effective than treating illness and disease; therefore, both approaches help to reduce healthcare expenses.

The nurse has an integral role in health promotion. The nurse's aim should be to teach patients how to remain healthy, thus preserving wellness. The overarching goal is to ensure that patients understand the importance of setting health goals for themselves and their children and that patients are able to assess, implement, and evaluate the goals, and modify them as their health needs change. Some examples of how nurses participate in health promotion include providing health education at every opportunity; evaluating and screening patients to identify prevention opportunities such as immunizations; and promoting wellness in the community by organizing and participating in community events such as health fairs.

Examples of current health promotion topics, identified both by *Healthy People 2020* and by individual states and communities, are childhood obesity and nutrition, physical activity across the lifespan, dental/oral health, tobacco use and smoking cessation, and health screening recommendations.

By implementing health promotion strategies, the nurse has an opportunity to step out of the secondary prevention area and into the primary prevention area. This shift increases nurses' satisfaction because they have an opportunity to contribute to the health of all patients—not just those who are ill but also those whose overall health status is free of illness, such as smokers who are disease free.

Secondary Prevention

Secondary prevention activities are aimed at early disease detection and treatment to prevent the progression of the disease and its associated symptoms. Screening is a means of early detection of diseases such as hypertension and vision or hearing problems. Screenings may be provided by primary healthcare providers and through health fairs. They may be offered to the general population or focused on groups at high risk.

Tertiary Prevention

Tertiary prevention involves restoring function and decreasing disease-related complications of an already established disease. When restoration to the previous level of functioning is not possible, care is focused on controlling symptoms and promoting the highest quality of life. Tertiary prevention includes rehabilitation and palliative care.

The three levels of prevention are summarized in **Table 46-1** ».

Healthcare Settings

Primary care is delivered in a variety of settings, including physicians' offices, hospital-based clinics, community health centers, and public health service locations (**Figure 46-1** »). Primary care should not be confused with primary prevention described in the previous section. Community health centers and public health organizations frequently offer health promotion activities at locations such as churches, shopping malls, and community cultural events.

In the context of managed care, the primary care setting is often the point of entry and the location of gatekeeping for all other care. Primary care involves the provision of health maintenance services such as routine physicals, immunizations, treatment of common acute illnesses, and support for psychosocial needs.

Secondary care is typically delivered in a hospital, outpatient surgical center, or specialist's office. The most cost-effective, efficient place of service should be selected as the optimal place of service. For example, a dermatologist may remove an adult's uncomplicated basal cell carcinoma in the office. In this instance, the office setting is the most appropriate, cost-effective place of service because removal of this type of lesion involves only a minor surgical procedure under local anesthesia.

Tertiary care that involves complicated diagnostic or therapeutic procedures may be provided in a place of service such as a hospital, a rehabilitation center, or an extended care facility. Wherever a patient receives tertiary care, the nurse, as the patient's advocate, will coordinate the patient's care and treatment and ensure the patient's compliance with treatment.

TABLE 46–1 Levels of Prevention

Level and Description	Examples
Primary Prevention	
Take action to prevent disease in generally healthy people and populations. Give people tools that empower them to improve their own health through positive actions such as smoking cessation and eating well.	<ul style="list-style-type: none"> Educate individuals, families, and populations on topics such as the importance of nutrition, exercise, dental hygiene, prenatal care, immunization, and smoking cessation. Educate employers and employees about occupational safety as well as avoidance of occupational hazards. Improve environmental sanitation and provide adequate housing and nutrition (e.g., removing lead from housing units, making fresh produce available in areas designated as food deserts).
Secondary Prevention	
Detect and then treat identified injuries and diseases early so that they can be cured or their associated symptoms and complications can be prevented or limited.	<ul style="list-style-type: none"> Perform risk assessments for healthy people who have risk factors for specific diseases such as coronary artery disease and diabetes; then work with each patient to develop and implement a risk reduction plan. Encourage regular dental, vision, and medical screening examinations for children and adults (primary care providers should follow guidelines such as <i>Healthy People 2020</i> or the recommendations of the U.S. Preventive Services Task Force when evaluating patients' screening needs). Teach patients to perform self-screening examinations such as testicular examinations and mole checks for possible melanoma. In all settings, develop and implement care plans to treat patients' illnesses and injuries (e.g., administer medication and treatment regimens) and prevent complications (e.g., turn, position, and exercise patients to prevent pressure ulcers and deep venous thromboses); ensure adequate rest, food intake, and fluid intake to promote healing and promote fecal and urinary elimination.
Tertiary Prevention	
Begins after a condition is treated and stabilized or recognized as incurable. Includes the restoration of function and decrease of complications of an established disease. If restoration to the previous level of function is not possible, care focuses on controlling symptoms and promoting the highest quality of life possible. Rehabilitation and palliative care are included in tertiary prevention.	<ul style="list-style-type: none"> Refer a patient with a new urostomy to an RN ostomy management specialist to learn how to care for and improve life with an ostomy. Refer a patient with diabetes to a registered dietitian for education on how diet can affect the complications of diabetes. Refer individuals with severe or chronic pain to a pain specialist to manage pain with an appropriate medication regimen and/or alternative treatment methods. Refer individuals with mobility issues to physical therapy or rehabilitation services to promote mobility and prevent falls and other mobility-related complications.

Figure 46–1 » Nurses practice in many healthcare settings. Clockwise from top left: **A**, a nurse in the emergency department with a patient coming in from a medical flight; **B**, a surgical nurse in the OR; **C**, a nurse in a pediatrician's office; **D**, a nurse working in a rehabilitation hospital; **E**, and a nurse in the neonatal intensive care unit. Other settings where nurses work include schools, public health departments, patient's homes, prisons, insurance companies, colleges and universities, and publishing companies.

Factors Affecting Delivery of Healthcare

A number of factors affect the ability of the nurse to deliver patient care, regardless of the competency or proficiency of the nurse or the level of care or the setting in which care is being delivered. These include changing demographics, advances in technology, and levels of health literacy of patients in the community.

Changing Demographics

By the mid-21st century, the United States will be more racially and ethnically diverse, as well as much older, according to projections released by the U.S. Census Bureau (2014). Life expectancy is also expected to increase among all groups. The other major change that will impact healthcare delivery systems is drivers of mortality. Whereas the rates of smoking have decreased among those age 25–44, the rates of obesity have dramatically increased between 1980 and 2008, doubling for adults and tripling for children. This will lead to increases in obesity-related conditions such as adverse lipid concentrations, type 2 diabetes, and hypertension.

Advances in Technology

Scientific knowledge related to healthcare continues to increase rapidly, leading to ever more sophisticated technology. Information management systems have been created and are continually being refined. Such systems support bedside charting, barcoding for medication administration, and use of online evidenced-based guidelines to provide appropriate care. Advances in laparoscopic surgical techniques have resulted in fewer hospitalizations for some surgeries because they can safely be performed at alternative sites such as surgical centers. Other treatments such as minimally invasive surgical techniques may shorten or eliminate hospital stays. Many advances in technology require specialized personnel, creating new opportunities for individuals seeking employment in the healthcare sector.

Health Literacy

Health literacy is defined as the capacity to obtain, communicate, process, and understand basic health information and services to make appropriate health decisions (Koh et al., 2012). A systematic review found that low levels of health literacy lead to a reduced ability to interpret health messages, a limited ability to take medications correctly, a lower likelihood of receiving preventive care, increased hospitalizations, and higher use of emergency care (Berkman et al., 2011). In the only population-level survey conducted by the National Center for Educational Statistics in 2003, researchers found that only a slight majority of adults had intermediate health literacy skills and 36% had a basic or below basic level. Despite this, our healthcare systems function as if all patients have literacy skills (Koh et al., 2012). For many tasks in the healthcare systems, patients must employ print literacy (writing and reading), oral literacy (listening and speaking) and numeracy (using and understanding numbers such as medication dosages).

Healthcare illiteracy and ineffective communication place patients at risk for poor health outcomes. According to the

National Institutes of Health (2013), African Americans, Hispanics, Native Americans, and Asian Pacific Islanders, representing about 25% of the U.S. population, continue to experience health disparities, including shorter life expectancy and higher rates of diabetes, cancer, heart disease, stroke, substance abuse, infant mortality, and low birth weight. Providing health education programs for these populations is one of the key strategies for overcoming this health disparity.

Health literacy also involves policies and strategies at the organizational level. Agencies that strive to be health-literate organizations continuously work to improve verbal interactions, improve written communications, link to support systems, and engage patients and caregivers as partners in care and improvement efforts. Technology also plays a role. Many agencies offer virtual patient portals and websites that provide an array of evidence-based information and resources ranging from topics such as how to prepare a child for surgery to tips on how to care for loved ones with chronic illnesses.

Frameworks for Providing Care

In the United States, the three common models of healthcare are managed care, case management, and patient-focused care. Sometimes the frameworks overlap (e.g., services may be coordinated through a case management model to patients whose health insurance plan uses a managed care model).

Managed Care

Managed care, discussed in detail in the module on Managing Care, is a method of delivering cost-effective and high-quality care. Managed care is designed to improve outcomes for groups of patients; its framework can be adapted across all healthcare settings. The primary managed care models are health maintenance organizations (HMOs) and preferred provider organizations (PPOs). HMOs are more restrictive than PPOs and require that a patient select a primary care physician who manages the patient's secondary and tertiary services. Although a PPO is less restrictive, the direct costs to the patient are higher (e.g., higher premiums, copayments, and deductibles).

Case Management

The Case Management Society of America (2012) defines **case management** as “a collaborative process of assessment, planning, facilitation and advocacy for options and services to meet an individual's and family's comprehensive health needs through communication and available resources to promote quality, cost-effective outcomes.” Multidisciplinary teams led by a case manager are at the heart of successful case management. Case management is essential when a patient has multiple care needs and requires the services of multiple providers. The goal of case management is to reach and then maintain the individual's optimal level of health, quality of life, and activities of daily living (ADLs) by ensuring that the individual's healthcare needs are met. The case manager may be a nurse, a social worker, or another healthcare team member. Case management enables patients to experience continuity of care, regardless of the location at

which the care is provided. This activity on behalf of a patient may be limited to a hospitalization or may occur across settings for patients receiving care in the community and/or at home.

Patient-focused Care

Patient-focused care is a delivery model that organizes healthcare around the expressed physical and emotional needs of the patient. Patient-focused care is generally understood to be an approach that considers patients and their families to be integral to decisions regarding healthcare delivery.

Access to Healthcare

For most Americans who have healthcare coverage through an employer, high-quality healthcare is available without a long wait and at a reasonable cost. However, such healthcare is often beyond the reach of the many Americans who work for small employers, the unemployed and underemployed, the self-employed, the poor, and members of underserved minorities. These groups face many challenges to accessing healthcare and, as a result, often have poorer health outcomes—in some cases worse than those of residents of developing countries. A 2011 report from the Agency for Healthcare Research and Quality (AHRQ, 2011), titled *National Healthcare Disparities Report*, confirms that people of racial and ethnic minority groups and those of low socioeconomic status have disproportionately more access problems than others. Inadequate access to healthcare has a large impact on society. For example, a failure to receive immunizations against or early treatment of contagious diseases can result in community outbreaks. The healthcare reform acts signed into law by President Obama in early 2010 were designed to remedy some of the disparities in access to health insurance coverage and other related problems.

Uninsured individuals are those without any type of healthcare coverage. Uninsured individuals do not qualify for public health insurance programs, such as Medicaid, and cannot buy health insurance, usually because they work for employers who do not offer health insurance coverage. Uninsured patients also include those who cannot afford to purchase insurance through their employer because the insurance premiums are too expensive. During recent decades, even individuals who were self-employed had difficulty purchasing health insurance privately, either because the premiums were unaffordable or because they were denied coverage because of preexisting conditions. One of the most popular provisions of the Affordable Care Act was that it prevented insurance companies from denying coverage based on preexisting conditions, even for those who with employer-based insurance. **Underinsured** individuals have healthcare coverage that is insufficient to meet their needs. Examples include the child who is covered under a parent's company policy, but the policy does not include immunizations, and the patient with a chronic illness whose insurance does not include coverage for medications. Continued healthcare reform may resolve these gaps in coverage.

Access to healthcare means having “the timely use of personal health services to achieve the best health outcomes” as documented in the Institute of Medicine's 1993 report titled *Access to Healthcare in America*, a document that is still widely cited today. As noted in the report and more recently quoted in *Healthy People 2020*, accessing healthcare requires three discrete steps:

1. Gaining entry into the healthcare system
2. Getting access to sites of care where the patient can receive needed services
3. Finding providers with whom the patient can communicate, develop a trusting relationship, and have individual needs met.

Lack of Health Insurance

In 2013, the rate of uninsured non-elderly had dropped to 16.7%, and it continued to drop over the next 3 years. As of January 2017, some 28 million people were enrolled through the ACA Marketplace (12.2 million) or Medicaid expansion (over 16 million) (Centers for Medicare & Medicaid Services, 2017; Macpac, 2017; Mangan, 2016). Many of these newly insured had gone without insurance for long periods of time. The largest gains in coverage were seen among poor and low-income individuals and people of color. Hispanic and Black populations had the largest declines in uninsured rates. Despite these improvements, there are still people who do not have health insurance.

The primary reason individuals are uninsured is that they cannot afford to be insured. Some 3 million poor uninsured adults earn too much money to qualify for Medicaid. People who are uninsured may delay treatment or opt not to receive it because they must choose to pay either for medical care or for basic necessities such as food and housing. Most uninsured individuals do not receive healthcare services for free or at a reduced charge and are often billed at a higher rate. In 2014, one third of uninsured adults had medical debts sufficient to put them at risk of bankruptcy (Henry J. Kaiser Family Foundation, 2015).

Children with health insurance are more likely to stay healthy and do well in school, setting them on a course for better health and better opportunities throughout their childhood and teens. Children with healthcare coverage receive preventive care; are treated for sickness and injuries when they occur; are immunized against childhood diseases; are seen for well-child visits required for participation in school and sports; and receive treatment for recurring illnesses such as ear infections. Well children are more likely to attend school regularly and have an easier time focusing on their schoolwork (Insure Kids Now, 2013).

The Affordable Care Act affected children favorably because it prevented insurance companies from denying coverage for preexisting conditions and from dropping insured individuals or their dependents because of the onset of serious illness (Henry J. Kaiser Family Foundation, 2013).

SAFETY ALERT In 1986, Congress enacted the Emergency Medical Treatment and Active Labor Act (EMTALA) to ensure public access to emergency services regardless of ability to pay. Prior to the enactment of this law, providers of emergency services often refused to treat patients who were uninsured and who could not afford to pay

for services. Under Section 1867 of the Social Security Act, Medicare-participating hospitals that offer emergency service must provide a medical screening examination (MSE) when a patient asks for examination for or treatment of an emergency medical condition (EMC), including active labor. The law requires that this service be provided regardless of an individual's ability to pay. Hospitals must also provide stabilizing treatment for patients with EMCs. If unable to stabilize a patient or if the patient requests it, the emergency care provider must arrange for an appropriate transfer (EMTALA, 2011).

Lack of a Usual Source of Care

According to the AHRQ (2011), individuals with a *usual source of care* (i.e., a facility where the individual regularly receives care) experience improved health outcomes, fewer health disparities, and lower costs. A usual source of care is sometimes referred to as a *medical home* or *healthcare home*.

If a patient has a primary care provider (i.e., a physician or nurse from whom the patient regularly receives care), trust and communication between the patient and provider are improved, resulting in the likelihood that the care provided to the patient will be appropriate and of high quality (AHRQ, 2011). A primary care provider who learns about the diverse needs of patients over time is better able to meet those needs. Despite this fact, over 40 million Americans do not receive regular care from a primary care provider.

The United States Department of Health & Human Services (USDHHS), the American Academy of Pediatrics, and the American Medical Association developed national guidelines for preventive health services for infants, children, and adolescents (**Box 46–1** >>>). These guidelines are supported by the National Association of Pediatric Nurse Associates and Practitioners (NAPNAP).

Children and families are better served when they have a usual source of healthcare that allows parents to forge an ongoing relationship and a high comfort level with their provider and increases the likelihood that they will seek healthcare for their children. Providers are able to give comprehensive, family-centered treatment because of their knowledge of the child and family, including the family's dynamics, possible risks, and need for protection. One source of such treatment is the patient-centered medical home, which is not a location but a standards-based approach to providing primary care in which the healthcare facility forges a partnership with the patient and the patient's family (**Box 46–2** >>>).

Box 46–2

Six Principles of a Patient-centered Medical Home

The most standard definition of a patient-centered medical home is provided in the *Joint Principles of the Patient-Centered Medical Home*, adopted by the American Academy of Family Physicians, American Academy of Pediatrics, American College of Physicians, and the American Osteopathic Association in 2007. This groundbreaking concept is still in use and was quoted by Andrea Bachrach et al. (2011) in *Pediatric Medical Homes: Laying the Foundation of a Promising Model of Care*.

This joint statement defines medical homes as both “an approach to providing comprehensive primary care for children, youth and adults” and “a healthcare setting that facilitates partnerships between individual patients, and their personal physicians, and when appropriate, the patient's family.” It lists seven principles that characterize medical homes. Six are listed below; the seventh (omitted here) addresses appropriate payment to medical home providers.

1. **Personal physician.** Each patient develops an ongoing relationship with a personal physician who provides comprehensive medical care from the initial visit onward.
2. **Physician-directed medical practice.** The patient's personal physician leads a healthcare team that works together and accepts responsibility for the ongoing care of the patient.
3. **Whole person orientation.** The personal physician, who is responsible not only for providing and overseeing medical care to the patient but also for ensuring that all healthcare needs are met, prevents fragmentation of care by arranging for and following up on care provided by other qualified professionals, such as specialists, and ensuring that the patient returns to the medical care home.
4. **Coordinated and integrated care.** Care must be coordinated and/or integrated across all elements of the complex healthcare system and the patient's community, and it must be provided in a way that meets the patient's cultural and linguistic needs. Coordination and integration are facilitated by using strategies such as electronic health records and health information exchanges.
5. **Quality and safety.** Quality and safety are critical elements of the medical home.
6. **Access to care.** Access to care is facilitated by systems such as open scheduling; expanded hours; and improved means of communication among patients, their personal physician or nurse practitioner, and practice staff.

Perceptions of Need

Perceived need often affects an individual's decision to access the healthcare system. Patients may not always be able to assess their own need for care. However, when they believe they need care for illness and injury and are unable to obtain it, they perceive that care is difficult to access. These perceived difficulties include delays in getting care as soon as it is wanted.

Clinical Example A

A nurse working for a large insurance company as a telephone triage nurse receives a call late at night from a member reporting that her 4-year-old daughter woke with ear pain that has not responded to acetaminophen administered by mouth 15 minutes ago. The mother reports that the child is crying in pain and requests authorization to go to the hospital emergency department. The nurse provides strategies to treat the child's pain and explains that oral analgesics require 45–60 minutes to begin taking effect. The nurse offers to make an appointment with the primary care provider in the morning. When the mother states that the child must be seen immediately, the nurse suggests that the mother take the child to a 24-hour urgent care center. The mother declines, insisting that the child be treated immediately at the emergency department.

Critical Thinking Questions

1. Does this nurse have the right to inform parents they cannot take the child to the emergency department because this is not an emergency?
2. How does the mother's perception of need affect her response?
3. What else might the nurse do to help the parent more accurately perceive the child's healthcare needs?

Uneven Distribution of Services

The distribution of healthcare services in the United States is problematic because it is uneven. Many geographic areas and populations are medically underserved. Rural areas come to mind as areas that are likely to lack medical resources; however, suburban and urban areas may also be underserved because of poverty as well as cultural and linguistic barriers to healthcare access. Another factor that causes a community or population to be underserved is a shortage of primary care professionals such as primary care physicians, nurse practitioners, nurses, and physician assistants. Availability varies from region to region, from state to state, and even within cities themselves, where the poorest communities may be underserved.

This uneven distribution is seen across professions in the healthcare field. There are 3.1 million registered nurses in the United States and the District of Columbia. Except for California and Texas, the states with the highest number are found in the eastern half of the U.S. The same pattern holds for nurse practitioners, who numbered 153,092 in 2016. Family medicine practitioners are only slightly more evenly distributed. There are no states that have enough primary care providers to meet their needs. The desirable ratio of primary care physician to population is 1 to 3000, assuming the needs of the population are average (Henry J. Kaiser Family Foundation, 2016). Uneven distribution is aggravated by the increasing number of healthcare providers who specialize. This shift to specialization decreases the number of primary care providers who are available at any given time. Specialization can be advantageous, given the complexity of healthcare today, but it is also disadvantageous because it may increase fragmentation of care and costs. Increased specialization is a factor that increases the need for care management.

Solutions

The United States has addressed and continues to address the problem of the uninsured and the underinsured in many ways. Although controversial, the most far-reaching

recent solution has been the Affordable Care Act, which was created to ensure that all U.S. citizens have access to affordable, quality care and to curb the growth of healthcare costs. The ACA will likely be changed significantly in the coming years.

» **Stay Current:** Keep abreast of the changes in healthcare and insurance laws by visiting the U.S. Department of Health & Human Services at <https://www.hhs.gov/healthcare/about-the-aca/index.html> and Medicaid.gov at <https://www.medicaid.gov/affordable-care-act>.

Other older programs include the following:

- Medicare for older adults
- Medicaid, which assists people with lower incomes and older adults who require services not covered by Medicare, such as nursing homes, as well as some people with disabilities.
- CHIP, which assists with coverage for children whose families earn too much to qualify for Medicaid coverage but too little to afford private health insurance.

Local health departments and community health centers are sources of care for individuals without health insurance or who have gaps in their coverage. Community health centers offer primary and preventive care to millions of Americans for free or at a low cost. Anyone may obtain care from these clinics regardless of income. The cost of care is determined by using a sliding scale that is based on an individual's income (HealthCare.gov, 2013). The ACA increased the funding so Medicaid pay to physicians is increased for 2 years and the availability in many states has risen by 8% (Blumenthal et al., 2015). In addition, the ACA has funded the National Health Service Corps for physicians and re-funded the Nurse Service Corps for nurses to support education and loan repayment.

As illustrated in the clinical example above, a patient's perceived need for healthcare services can be a barrier to access. It may cause patients to seek care that is unnecessary or care that is necessary but provided at an inappropriate and often more expensive place of service than needed. The nurse can change the patient's perception of need (thereby promoting appropriate and timely healthcare) by managing patient care; teaching adults about self-care and the care of their children; and teaching them when and how to access appropriate care.

Implementation of a team approach to healthcare favorably affects the availability of primary care. As physicians are teamed with nurses and nurse practitioners who manage those aspects of patient care that do not require a physician's expertise, physicians will have more time available to devote to those elements of care requiring their knowledge and skills.

Clinical Example B

Helena Alvarez is a pregnant, 19-year-old woman, who arrives at the emergency department of a small rural hospital with severe cramping pains and bleeding. She has no health insurance. No maternity services are available at this hospital, and no obstetricians are available in the community. There is a tertiary care facility about 100 miles away.

Critical Thinking Questions

1. How would you determine what options are available for providing care for Ms. Alvarez?
2. As a nurse, what are your obligations to Ms. Alvarez?

Nursing Care Delivery Systems

Three models of nursing care delivery are frequently used where patient care is provided. These are functional nursing, team nursing, and primary nursing.

Functional Nursing

Functional nursing is a task-oriented approach to care delivery. Although it is not used routinely, it may be implemented when systems are stressed by factors such as inadequate staffing resulting from nursing shortages or significant weather events such as major snowstorms. In this approach, the head nurse delegates tasks to team members who complete these specific tasks rather than caring for specific patients. For example, one nurse is responsible for delivering medications and changing dressings while another performs administrative functions such as monitoring orders and communicating with physicians and other departments to arrange for services. Functional nursing is an efficient approach because it enables the nursing team to complete many tasks in a short time. **Unlicensed assistive personnel (UAP)** are a critical component of functional nursing. They are paraprofessionals who are unlicensed but may be certified. The primary role of the UAP is to assist patients with ADLs and provide other types of basic care. UAPs act under the direction of licensed professionals such as registered nurses who delegate activities to them. When UAPs assist patients with activities such as feeding, bathing, and ambulating, registered nurses are able to focus on performing more complex tasks.

Because fewer nurses are needed, functional nursing is cost effective. However, depersonalization and fragmentation of care may result because there is limited opportunity for team members to view the patient holistically. Nurses often become dissatisfied with their role in patient care because it is limited to tasks. Patients also may be dissatisfied because they cannot identify “their nurse,” that is, one individual who is responsible for their care.

Team Nursing

Team nursing is the delivery model most frequently used today. It is a means of providing individualized care to patients that was developed in response to the fragmentation of care inherent in the functional model. The registered nurse who serves as the team leader is accountable for the care provided to the patients assigned to the team. The team leader retains responsibility and authority for the patients’ overall well-being but delegates some tasks to UAPs. Team members are assigned tasks based on their ability to perform them. While this model frees the professional nurse to attend to more complex patient care tasks, frequent changes in assignments may lead to a lack of continuity of care for patients. A modification to the team nursing concept is pod nursing. In pod nursing, larger units are broken down into smaller pods and teams of nurses and UAPs work together in closer geographical areas where they have closer access to supplies to keep them closer to their patients. This model maintains smaller teams with greater degrees of partnership (Friese et al., 2014).

Primary Nursing

In the **primary nursing** model, one nurse has 24/7 authority and responsibility for the care of an assigned group of patients. The primary nurse (PN) cares for the assigned patients during her shift from the time of admission through discharge. Primary care nursing is a relationship-based model of care. The PN is responsible for assessing patients, developing care plans, and providing direct care. When the PN is absent, an associate nurse will provide care under the guidance of the care plan developed by the PN. In this model, UAPs are actively involved in providing direct patient care and are assigned tasks by the PN or associate nurse in the PN’s absence.

Concepts Related to Healthcare Systems

Healthcare systems refers to the broad array of people, institutions, and resources that provide care to people locally, within a state, across the nation, and internationally. Care is provided at many different places of service, and the nurse must be prepared to function in each. Each of these components of the healthcare system faces its own ethical dilemmas, legal issues, managed care issues, and clinical decision-making challenges. These challenges are particularly acute in a time of disaster, when concise, accurate, and timely communication becomes even more important. For example, nurses will face ethical and legal issues associated with the provision of care in mass casualty events (MCEs) (e.g., who will not receive care, who will receive care, and when and where care will be provided). They will also be challenged as they decide what care to provide to the patients they are caring for during a disaster (e.g., when has sufficient care been provided to permit the patient to be transported, and how does one safely provide care when resources are strained?). Communication among the various emergency team members must be concise, accurate, and timely during an MCE. Nurses must use their knowledge to foster better communication. The Concepts Related to Healthcare Systems feature lists some, but not all, of the concepts integral to healthcare systems. They are listed in alphabetical order.

Resource Allocation

For more than two decades, the escalating cost of healthcare in the United States has been a concern. Gaining control over increasing healthcare expenditures has been a goal of both the government and private entities. Many factors are responsible for the increasing cost of healthcare. These include increased longevity, increases in the prevalence of chronic diseases such as diabetes, continued medical advances (which may result in more accurate diagnoses and better treatment but are often more expensive than existing methods), technologic advances, consumer demand, and defensive medicine (ordering a test or procedure to avoid litigation). Inappropriate healthcare treatment choices by consumers have also contributed to increased healthcare costs. As discussed in the module on Managing Care, employees have enjoyed the benefits of employer-negotiated

Concepts Related to Healthcare Systems

CONCEPT	RELATIONSHIP TO HEALTHCARE SYSTEMS	NURSING IMPLICATIONS
Communication	Because of the uncertainties, confusion, and sheer demands of an emergency, communications may be fragmented and difficult. Yet an emergency is the very time when clear, effective communication is critical.	<ul style="list-style-type: none"> You will immediately identify and communicate important information to the individuals in charge. You will continually communicate information with others on the team to which you are assigned. You will ensure that documentation regarding patient condition, treatments completed, and so on, is maintained and transported with the patient to ensure a smooth transition in care and to prevent harm to the patient. You will use tools for communication (e.g., SBAR) that result in concise exchanges of critical information.
Ethics	A nurse who is in the midst of a disaster faces many ethical dilemmas. Perhaps the first is whether to provide care (i.e., “show up”). The nurse, who is trained to provide the best care possible to any assigned patient, may be challenged by decisions made for the greater good, such as not providing care to individuals who are unlikely to survive and keeping care for others very basic to preserve available resources.	<ul style="list-style-type: none"> Develop an individual disaster plan for yourself and your family so that it will be easier to make a decision to participate during a disaster or not. Familiarize yourself with the disaster preparedness plans of your employer and community, which will facilitate a decision and, by virtue of having a plan in place, will make it easier to respond. Participate in disaster drills, which will enable you to understand the requirements of participation and make a quicker decision about participation. Obtain CERT (Community Emergency Response Team) Training. Never exceed your professional scope of practice, because doing so may result in loss of your license and subject you to personal liability for negligence or malpractice. Ensure that you understand the Code of Ethics and Standards of Practice of the American Nurses Association (ANA) and how they relate to emergency situations.
Legal Issues	Despite the good intentions of nurse volunteers, they must understand that state and federal law may not provide legal protection if the nurse is practicing outside of the jurisdiction where the nurse is licensed.	<ul style="list-style-type: none"> If you plan to respond to disasters, then volunteer with a disaster registry, such as federal disaster medical assistance teams nationally or locally with the American Red Cross. Doing so will provide you with the proper credentialing and training necessary to respond to a disaster, and your participation will be less problematic because you are part of an organized system. Know your state’s laws regarding emergency response, and ensure that you adhere to the requirements of your state licensing board.
Managing Care	Care coordination will be required to ensure that the needs of disaster victims are met. The leader of the disaster team will work with all present to ensure that the medical emergency response is effective.	<ul style="list-style-type: none"> Know the disaster plans for your employer and be prepared to follow them. When you report to the disaster team, immediately go to the command center to receive your assignment rather than beginning care where you stand. You may need to delegate care to other individuals; ensure that, despite the emergency, you follow the principles of delegation (e.g., confirm that the delegate has been trained to perform the procedure, understands the procedure, completes the procedure, and reports back).
Perioperative Care	One of the outcomes of triage will be determining which patients will need to go to the OR now or which ones can be stabilized and sent to the OR later.	<ul style="list-style-type: none"> Know the disaster plans for your employer and be prepared to follow them. The nurse will need to assist with quickly preparing patients for the OR, while ensuring that all critical safety procedures are done such as timeouts, site marking, and appropriate patient identification. The nurse will use tools for communications such as SBAR to ensure a safe and complete handoff.

insurance plans but, as patients, have been insulated from and are often unaware of the cost of care, resulting in uninformed decisions about the type and amount of healthcare needed. Mass advertising by pharmaceutical manufacturers and specialty treatment centers directed at consumers has also contributed to inappropriate treatment choices being made by the public.

As healthcare expenditures have increased, the need for **resource allocation**, the distribution of resources among competing groups of people or programs, has been recognized. When resources are being allocated, three levels of decision making must be considered:

Level 1: Allocating resources to healthcare versus other social needs

Level 2: Allocating resources within the healthcare sector

Level 3: Allocating resources among individual patients (AHC).

Clinical Example C

An 8-year-old boy with a chronic blood disorder requires weekly blood transfusions. The hospital struggles to maintain enough of his rare blood type. The 8-year-old arrives at the emergency department at the same time as another patient who is bleeding profusely and has the same blood type. There is enough blood for only one of these patients.

Critical Thinking Questions

1. Which patient should receive the blood? Why?
2. What models or methods should be used to make the decision? Who should be responsible for making the decision?

Examples of Resource Allocation

Rationing is one means of allocating healthcare resources. Rationing is a method used by individuals, insurance companies, and the government to prevent increases in the cost of healthcare or to reduce the cost of healthcare. Individuals ration when they decide to provide self-care for an illness or injury rather than seeking care from a healthcare provider. Methods used by insurance companies to ration healthcare resources include limiting the number of healthcare providers that patients can choose and denying coverage for services (e.g., services deemed to be experimental or those that are not supported by scientific evidence that prove their efficacy). The government also rations healthcare resources, such as inclusion of the coverage gap in Medicare Plan D (known as the “donut hole”) that sometimes forces beneficiaries to purchase fewer prescriptions (Torrey, 2012).

The Organ Procurement and Transplantation Network

One of the best-known systems of allocating certain healthcare resources is the Organ Procurement and Transplantation Network (OPTN). In the United States, on average 92 people receive a donated organ each day (USDHHS, 2017a). There are currently almost 120,000 people awaiting organ transplantation, and 75,000 are on the active waiting list. Unfortunately, there simply are not enough donated organs to meet the demand for transplants. The OPTN, a contracted service of the USDHHS, maintains the only national patient waiting list for organ transplantation. Multiple factors determine

who receives a donor organ. A few of the factors are blood and tissue type, medical urgency, organ size, time on the waiting list, and the geographic distance between the donor and the recipient (USDHHS, 2017b).

» **Stay Current:** More information on organ donation, including statistics updated daily and how to register as a donor, can be found at <http://optn.transplant.hrsa.gov>.

H1N1 Vaccine Distribution

During 2009, there was an outbreak of H1N1 influenza. Initially an inadequate supply of vaccine was available, but as H1N1 began to spread, the Centers for Disease Control and Prevention (CDC) realized that guidelines had to be developed and implemented to ensure that the most vulnerable individuals had first access to the vaccine. As more vaccine became available, the CDC (2009) rationed its distribution by considering factors such as the amount of vaccine being requested by local health departments, the speed at which the vaccine was becoming available, and the need to ensure availability for not only the community but also active-duty military personnel.

Once the vaccine arrived in local communities, further decisions were made about who could receive it if the supply was insufficient to meet the demand. Many local health departments screened potential recipients and initially administered the vaccine only to individuals with risk factors for H1N1, such as small children and adults with diagnosed respiratory disease (**Figure 46-2** »). Later, when sufficient quantities of the vaccine became available, healthcare providers were able to administer the vaccine to anyone who asked for it.

Nurses and Allocation of Resources

The role of the nurse in the allocation of resources is a collaborative one. Nurses are the largest group of health professionals, and as part of the interprofessional healthcare team, the nurse participates in allocating healthcare resources. Thus, nurses develop a significant understanding of how appropriate allocation and misallocation of healthcare resources can affect patient needs and outcomes. Nurses must be aware of and participate in discussions that affect

Source: Tim Sloan/Staff/Getty Images.

Figure 46-2 » Hundreds of county residents wait in a long line for the H1N1 vaccination shot at a clinic held by the Montgomery County Health and Human Services on October 14, 2009, at the Dennis Avenue County Health Center in Silver Spring, Maryland.

the allocation of healthcare resources in the workplace, in their communities, and at the federal level. Nurses are uniquely placed to advocate on behalf of patients when allocation of resources is being considered in their communities. They may advocate by talking with local legislators, writing to politicians, and engaging in discussions in their

neighborhoods and social groups. As working professionals, nurses have the opportunity to participate in national discussions about resources through a number of professional organizations, such as the American Nurses Association.

REVIEW The Concept of Healthcare Systems

RELATE Link the Concepts

Linking the concept of healthcare systems with the concept of oxygenation:

You are a registered nurse leading a team that includes LPNs and UAPs on a critical care unit of a hospital. You are planning care for a patient on a mechanical ventilator.

1. What aspects of this patient's care may be delegated to UAPs?
2. What factors related to the delivery of healthcare may affect your ability to provide care for this patient, and how?

Linking the concept of healthcare systems with the concept of clinical decision making:

You are a registered nurse working in the emergency department (ED) of a rural hospital. Harvesting season has brought large numbers of Spanish-speaking families to the community. Almost all of the men and many of the women are migrant workers. A mother who speaks limited English brings her 5-year-old son to the ED. She says he has been vomiting for 2 days. He has a fever of 102 degrees. She says he does not have a regular healthcare provider. He is not enrolled in any type of health insurance plan.

3. What factors will affect your ability to plan care for the child?
4. Which model of nursing care delivery would most benefit the child and his mother? Why?

Linking the concept of healthcare systems with the concept of reproduction:

5. What resources in your community are available to uninsured pregnant women?
6. Are the risks to the fetus any greater or any different when the pregnant mother is uninsured? Explain.

Linking the concept of healthcare systems with the concept of ethics:

7. What provisions of the ANA Code of Ethics address resource allocation?
8. What ethical considerations do you as an individual value that might affect how you would determine resource allocation?

- Additional review materials

REFLECT Apply Your Knowledge

Juan Santiago, 41 years old, makes an appointment with a health-care provider he has never seen before for an annual physical examination. During the nurse's initial assessment, the patient explains that he has never had a complete physical because he has always been healthy and hasn't had health insurance. After his recent college graduation, he accepted a new job that offered full healthcare benefits, so he decided it was time to take care of his health. Although he appears anxious about what will happen during the exam, he does not ask any questions and avoids making eye contact with the nurse.

During the collection of his health history, Mr. Santiago reports smoking approximately 20 cigarettes per day, drinking 2–3 alcoholic beverages per week, and, until recently, working as a landscaper, a very physically demanding job. He describes the physical requirements of his new job as "a little bit of walking but mostly desk work."

During the physical examination the nurse notes a wound the size of a quarter on the anterior aspect of Mr. Santiago's left foot. It is erythematous and warm to the touch, and a small amount of purulent drainage seeps from the side of the wound. Mr. Santiago reports that the wound has been there for more than 6 weeks. He has applied over-the-counter antibiotic cream daily but it still has not healed. The nurse asks Mr. Santiago about his weight; he admits losing about 10 pounds in the past month but denies changing his diet.

1. Describe primary, secondary, and tertiary care requirements for this patient.
2. What referrals to other healthcare providers might be appropriate to assist in the treatment plan for this patient?
3. What type of assessment of health literacy would the nurse conduct with this patient before providing written information?
4. What factors will influence care delivery to this patient? How will that alter the nurse's approach to providing care for this patient?

>> Exemplar 46.A Emergency Preparedness

Exemplar Learning Outcomes

46.A Analyze emergency preparedness as it relates to healthcare systems.

- Describe the four phases of emergency management.
- Outline the organizations responsible for emergency management and response.
- Summarize the process of triage.
- Describe the safety zones used in site-specific disaster response.
- Summarize the methods used for handling bioterrorism disasters.
- Analyze the importance of collaboration during disaster response.
- Explain the role of nurses in emergency management and response.

Overview

An **emergency** is a sudden, often unforeseen event that threatens health or safety. A public emergency necessitating assistance from outside the affected community is a **disaster**. Disasters have three things in common: little or no warning before the event; available personnel and emergency services that are overwhelmed initially; and a serious threat to life, public health, and the environment. Infectious diseases may accompany disasters or can become disasters themselves. A **pandemic** is an infection that spreads rapidly around the world.

Emergency preparedness is the act of making plans to prevent, respond to, and recover from emergencies. The CDC recommends an *all-hazards* approach to emergency preparedness. This approach provides for general preparation, including training that can be applied in a wide variety of emergency situations. The impact on health and the healthcare system is similar regardless of the nature of the disaster. **Surge capacity** refers to a community's ability to rapidly meet the increased demand for qualified personnel and resources, including healthcare resources, in the event of a disaster.

The Four Phases of Emergency Management

Emergency management consists of four phases: mitigation, preparedness, response, and recovery.

Mitigation

The **mitigation** phase, which takes place both before and after an emergency occurs, consists of identifying potential hazards, taking action to reduce the likelihood of their occurrence, and minimizing the effects of those that cannot be prevented. An example of mitigation in an individual's disaster plan would be the purchase of flood insurance by someone living in a flood zone. Implementation of warning systems for tornadoes and tsunamis are examples of mitigation by local, state, or regional agencies. Installation of a warning system prior to an occurrence of a disaster is an example of excellent disaster planning. Installation after an event is an example of using lessons learned from a disaster to reduce the effect of future occurrences. Both examples are mitigation.

Preparedness

The **preparedness** phase takes place before an emergency occurs. Risks are assessed and plans are developed to

address them. Plans are designed to save lives and to assist first response and rescue teams that are often overwhelmed by the initial demands of an emergency. Emergency plans are developed at the federal, regional, state, and local levels. The Federal Emergency Management Agency (FEMA), the Department of Homeland Security, and the CDC identify national threats, create plans at the national level, and coordinate planning efforts among many people, agencies, and levels of government. They provide guidance for the development of plans in local communities. For communities, the most critical task performed during the preparedness phase is the development of an emergency operations plan. These plans often include multiple components that address each of the many hazards and natural disasters that the community may face. They include identifying, organizing, and training emergency personnel; stockpiling equipment and supplies; implementing communication and warning systems; establishing emergency operations centers; and implementing response and evacuation plans.

Ideally, the agencies that participate in the emergency plan's development will also be involved in emergency response efforts and, therefore, will understand the risks the community may face and the responses that will be required. When agencies prepare for emergencies in advance and continually update their plans over time, their preparedness efforts will be more effective and result in better outcomes for the community.

During the preparedness phase, individual nurses must gain an understanding of their expected roles in an emergency and prepare for them. Because nurses will be required to allocate scarce resources and supplies and make unbelievably difficult patient care decisions, they must understand the ethics associated with such choices. The ANA is a good source of information to guide nurses' understanding of their roles and possible consequences. Public health nurses have a specific role to play in this phase. They plan ahead of time in their communities to assess the region for populations at risk for access and functional needs during a disaster and develop care plans to address those needs. They also conduct training drills and evaluate operational plans and work with local stakeholders (Association of Public Health Nurses [APHN], 2014).

Nurses also must be aware of their employer's response plans and have a sense of how their state and local community will operate during an emergency. Nurses who choose to become disaster volunteers should register with an agency such as the American Red Cross to ensure they are properly trained and recognized as part of an organized system (ANA, 2016).

During the preparedness phase, nurses must also develop an emergency plan for themselves and their immediate families. When this plan is complete, nurses can be confident that their families are prepared to weather an emergency in relative safety. With this assurance, nurses who choose to assist in a disaster or who are required to remain at the hospital during a disaster will be able to leave their families without delay and remain available until no longer needed. FEMA and the Red Cross are two organizations that provide detailed information to assist individuals with the development of personal emergency plans. It is important for everyone to develop a plan for themselves and their families. They must ensure that not only the adults but also the children know what to do in an emergency. Plans should address the basic emergency needs of any disaster. They should also include instructions for specific disasters, such as tornadoes, that may occur in the individual's location. Everyone should assemble a disaster kit that can be used in place or taken if evacuation is necessary. Escape routes for disasters that could occur within the home itself (e.g., gas leaks and fires) or for disasters that would require mass evacuation (e.g., floods and hurricanes) should be determined. Meeting places should be designated—someplace inside or outside the home where the family can unite. Family members should be provided contact information in case they are separated during a disaster. Someone outside of the immediate area should be identified as a central contact if family members are unable to reach each other locally. It is very important to shut off utilities as directed by emergency authorities or when forced to leave home. Insurance, medical, financial, and other vital records should be duplicated and stored in an off-site, safe location. Special needs such as medications, medical equipment, and so forth, should be considered and availability planned for. Family members should be trained in first aid, including CPR. Review and update of the emergency plan on a regular basis are critical because someday one's life may depend on it.

Despite a community's best preparedness efforts, there will be instances when a variety of factors result in failure to meet community needs. The evacuation of New Orleans in advance of hurricane Katrina and the efforts to provide shelter immediately following Katrina are stunning examples of how preparedness efforts can fail (see **Figure 46-3** »).

Emergency Response

The third phase, **emergency response**, is the implementation of emergency preparedness plans. These plans provide a means for responders to save lives, prevent additional property damage, and meet basic human needs. As soon as possible, disaster victims are triaged and given appropriate treatment. Other emergency activities include search and rescue operations, opening shelters to house survivors, and repairing utility infrastructure (**Figure 46-4** »).

Source: Rick Wilking/Reuters/Alamy Stock Photo.

Figure 46-3 » Authorities in New Orleans ordered hundreds of thousands of residents to flee on Sunday, August 28, 2005, as Hurricane Katrina strengthened into a rare, top-ranked storm and barreled toward the vulnerable U.S. Gulf Coast city. Those who had vehicles were caught in traffic jams for hours.

The emergency response plan is followed during and immediately after the emergency, simultaneously with the community's assessment of the disaster's immediate effects. Community agencies such as local law enforcement, paramedics, and emergency department personnel, as well as local governmental staff employed in the disaster response unit, are responsible for implementing the overall plan and its components. Public health nurses are part of this response effort. They ensure that logistics are in place to support community care during the crisis and provide ongoing response planning during the incidence (APHN, 2014). Federal, state, and other outside resources support local efforts by providing first aid and other emergency medical assistance and by establishing or restoring communication and transportation. Public health nurses use population-based triage to assess communicable disease outbreak impact and needed response, assessing the probability of infectious diseases and addressing them, and identifying and providing support to individuals with mental health problems.

During the preparedness phase, nurses must become familiar with the emergency plans of their employers and communities. They must also familiarize themselves with the ANA's positions on nurses' emergency and disaster responsibilities. During the emergency response phase, nurses will put this information to use. The responsibility of nurses during an emergency, like that of other first

Source: John Minchillo/AP Images.

Figure 46-4 » Medical workers assist a patient into an ambulance during an evacuation of New York University's Langone Medical Center, Monday, October 29, 2012. The New York City hospital moved out more than 200 patients, including 20 infants from the NICU, after its backup generator failed when the power was knocked out by Hurricane Sandy.

responders, is to do the greatest good for the greatest number of casualties. During an emergency, nurses will be asked to perform the fundamentals of nursing practice but will do so in a very stressful environment under extraordinary circumstances. They will be working under intense time constraints and must care for each victim quickly, then move on to the next one. They should not use their time to provide care that will be of minimal or questionable benefit. Nurses must observe both the physical and mental status of victims and ensure appropriate triage and treatment. Advanced practice nurses who have received training in emergency and trauma care will have significantly greater responsibilities than nurses with less training. During the crisis, nurses should be constantly aware of their defined scope of practice and must not exceed it even when circumstances would seem to dictate otherwise.

Recovery

The **recovery** phase takes place after the emergency and is designed to restore the community to normal balance (restoration) or create a new, safer normal by updating the community's preparedness plan to address lessons learned during the emergency (mitigation). The recovery phase includes the reconstitution of government operations and services, if necessary, and includes the provision of public assistance by the private and public sectors. Other elements of the recovery phase may include rebuilding, reemployment, and the repair of essential infrastructure. During the recovery phase, each community must reassess risks and update plans to ensure that newly identified risks are addressed. Because of their education and experience, nurses are well qualified to participate in risk assessment

and planning at the local, state, and national levels following a disaster. Nurses are also perfect candidates to educate their patients and communities about disaster preparation. In particular, public health nurses conduct rapid ongoing needs assessments at intervals to determine health and critical resource capacity after a natural disaster and work with community stakeholders to plan for any long-term health concerns following an incident. They also participate in the reconstruction of critical services and evaluate the long-term impact of the disaster consequences on the community (APHN, 2014).

Responsibility for Emergency Management and Response

State divisions of emergency management act as the **local emergency management agency (LEMA)** for each state. This is a governmental agency with expertise in public safety, emergency medical services, and management. The U.S. Department of Homeland Security has created federal guidelines called the National Incident Management System (NIMS) that local governments must follow during an emergency or disaster. Local governments have the primary responsibility for emergency management and response. In the event of an emergency, first responders such as local fire departments and emergency medical technicians will be challenged to meet the needs of the public because of the sheer volume of assistance they will be asked to provide. In situations like this, citizen volunteers often act as extensions of the first responders. For this reason, it is beneficial for a community to develop a corps of trained citizens to provide such support.

In recognition of this, FEMA has developed the **Community Emergency Response Team (CERT) program** to prepare interested community members. Participants gain an understanding of their responsibility for preparing for a disaster so they will be ready to safely assist themselves, their families, and their neighbors. The CERT program provides citizens with facts about what to expect following a major disaster in terms of immediate services; alerts citizens to their responsibility for mitigation and preparedness; trains citizens in needed lifesaving skills with an emphasis on decision-making skills, rescuer safety, and doing the greatest good for the most people; and organizing teams that act as an extension of first responder services, offering immediate help to victims until professional services are on site (U.S. Department of Homeland Security, 2016).

The CDC manages the Clinician Outreach Communication Activity (COCA) program to ensure that clinicians have up-to-date information. COCA is designed to provide two-way communication between clinicians and the CDC about emerging health threats such as pandemics, natural disasters, and terrorism. COCA keeps a list of emergency preparedness and training resources offered by federal agencies and COCA partners.

» **Stay Current:** Visit www.bt.cdc.gov/coca/training.asp for COCA's list of conferences and training opportunities and to sign up for e-mail updates from COCA.

Nursing Competencies for Emergency Response

Nurses represent the largest pool of healthcare professionals and, for this reason, are called on to assist in mass casualty events (MCEs). Training in preparation for, recognition of, and response to MCEs will be beneficial to the nurse, the nurse's family, the nurse's employer, and the community. Some of the ways in which nurses have received training regarding MCEs include reading professional journal articles, participating in mock disaster drills, volunteering in community services, obtaining CERT certification, and actual nursing during an MCE. Emergency preparedness is a necessity, regardless of the nurse's educational preparation, area of expertise, or practice setting (Whitty & Burnett, 2012).

In 2003, the International Nursing Coalition for Mass Casualty Education (INCMCE) (2003) published educational competencies for registered nurses to facilitate their response to MCEs, with a strong recommendation that these core competencies be included in initial nursing education programs (**Box 46-3** »).

The National Nurse Emergency Preparedness Initiative is a highly interactive, web-based course that provides emergency preparedness training for nurses working in hospitals/acute care, schools, public health, ambulatory care, hospice/palliative care, long-term care, occupational health, and home health settings. This training focuses on providing opportunities for dynamic and interactive application of both theory and practice through scenario-based learning.

Box 46-3

Categories of Educational Competencies for Registered Nurses Responding to Mass Casualty Incidents

Core Competencies

1. Critical thinking
2. Assessment
3. Technical skills
4. Communication

Core Knowledge Areas

1. Health promotion, risk reduction, and disease prevention
2. Healthcare systems and policies
3. Illness and disease management
4. Information and healthcare technologies
5. Ethics
6. Human diversity

Professional Role Development

1. A description of nursing roles during MCEs
2. Identification of the most appropriate or most likely healthcare role for oneself during an MCE

Source: Based on Nursing Emergency Preparedness Education Coalition. (2003). Retrieved from <http://www.nursing.vanderbilt.edu/incmce/overview.html>.

» **Stay Current:** Visit the National Nurse Emergency Preparedness Initiative website at <http://nnepi.gwnursing.org> to sign up for its interactive learning module that teaches nurses about a critical thinking framework that can be applied during disasters.

Emergency Plans

Individuals and agencies that respond to MCEs are expected to act within the framework of emergency plans that were prepared in advance. Most agencies are mandated by law to develop plans that dictate the roles and responsibilities of all individuals who will respond during emergencies, disasters, and MCEs. Individual healthcare agencies such as hospitals, health departments, and residential facilities for older adults and people with disabilities will create emergency plans that prescribe the roles and responsibilities of their own employees. All nurses not only must familiarize themselves with the policies and procedures of the agency that employs them, but also must create an individual emergency plan for themselves and their families.

Triage

The process of **triage** involves prioritizing patients for treatment based on severity of illness or injury and in light of the supplies and resources available. The objective of triage is to ensure early assessment of patients and prioritize care based on severity of symptoms. Nurses perform triage every day in emergency departments. During a mass casualty event (more than 100 victims), the demand on nurses' knowledge and skills will be even greater. Mass casualties call for the implementation of **reverse triage**, in which the most severely injured or ill victims who require the greatest resources are treated last to allow the greatest number of victims to receive medical attention. A simple color classification system (START) is used to prioritize adult patients (see **Figure 46-5** »). A separate algorithm, Jump START, has been developed for pediatric victims (**Figure 46-6** »). It is recommended that emergency medical personnel be assigned to triage. This frees physicians and nurses to provide needed care.

Site-specific Disaster Zones

When a site-specific disaster occurs, access to the site of contamination is limited and safety zones are established. Examples of such disasters are the release of weapons, such as bombs, and toxic chemical leaks due to tanker car derailment. The designated safety zones should be located uphill, upwind, and upstream from the site of the disaster. The configuration of each zone will vary based on the site of the occurrence. Topography, weather, and the physical layout (buildings, roads, and so on) will play an important role in designating the zones. The initial site of the incident is considered the hot zone. Only personnel with appropriate protective equipment are allowed in the hot zone. **Box 46-4** » provides more information on zone breakdown.

Bioterrorism

Bioterrorism is the deliberate release of viruses, bacteria, or other microbes as weapons. The U.S. public health system and primary healthcare providers must be prepared to respond to and treat the diseases caused by these agents,

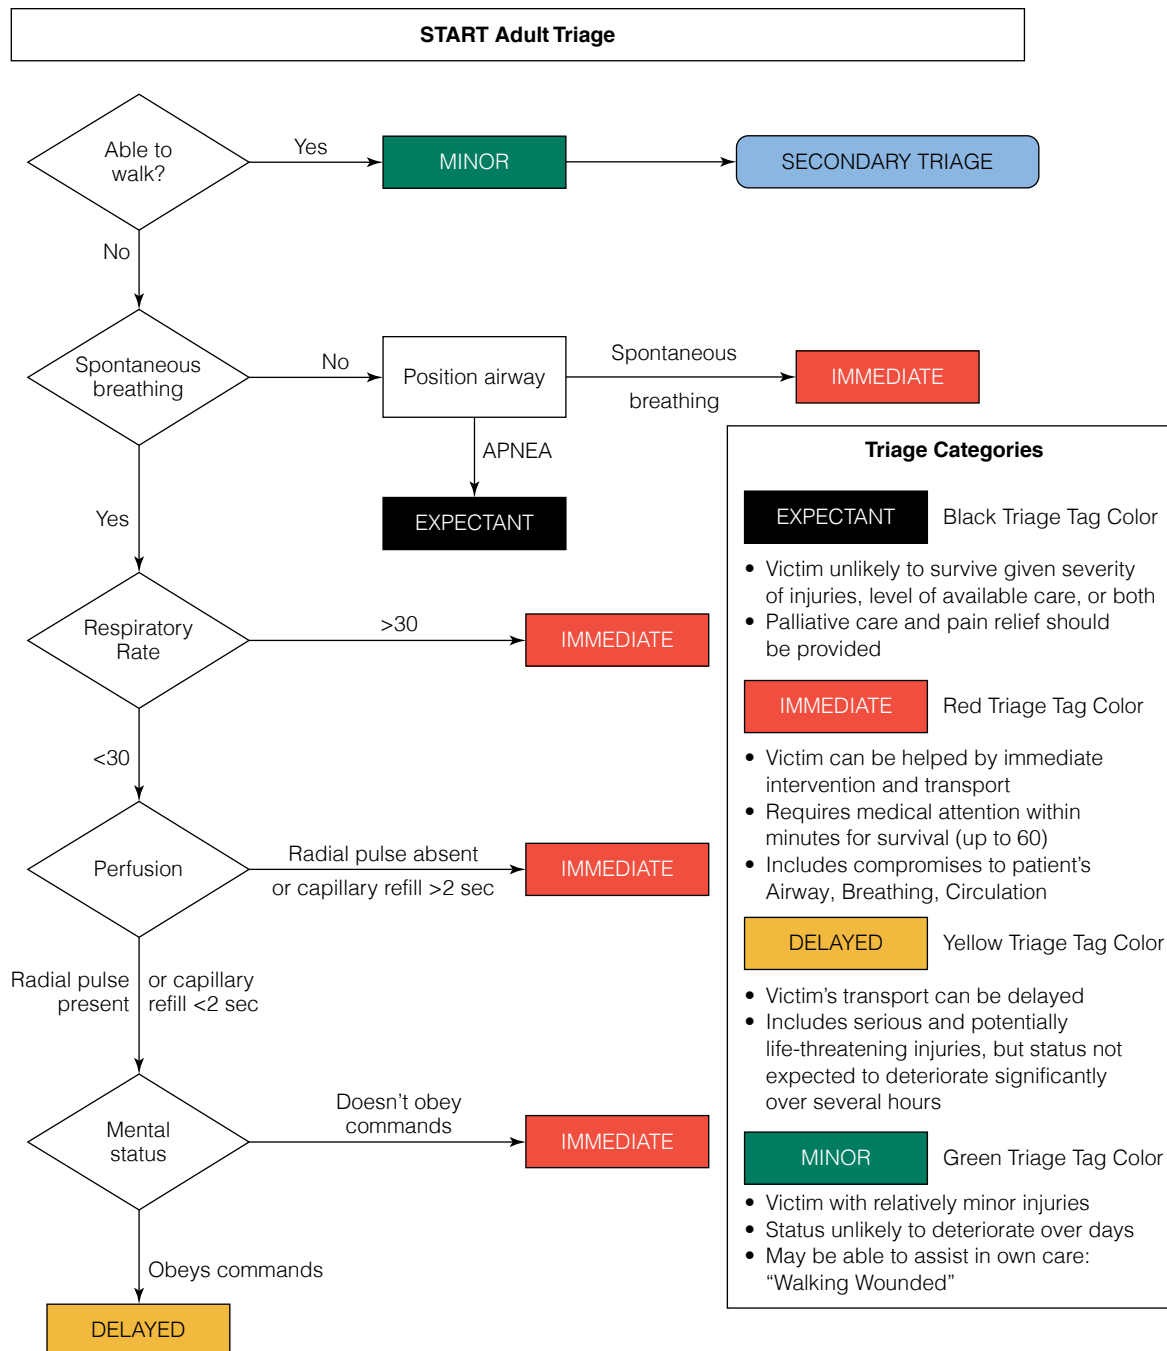

Figure 46-5 » START adult triage algorithm.

many of which are rarely seen in the United States. The CDC has assigned the highest priority to biological agents that can be easily disseminated or transmitted from individual to individual; cause a high mortality rate; have a significant impact on public health; cause public panic; and disrupt society and government. The primary agents identified by the CDC as potential bioterrorist threats are anthrax (*Bacillus anthracis*), botulism (*Clostridium botulinum* toxin), plague (*Yersinia pestis*), smallpox (variola major), tularemia (*Francisella tularensis*), and viral hemorrhagic fevers (filoviruses [e.g., Ebola and Marburg] and arenaviruses [e.g., Lassa and Machupo]) (CDC, 2013).

Nurses must be aware of the early signs and symptoms of these diseases as well as the methods of transmitting them. See **Table 46-2** ».

Immediate treatment for the primary biological agents used in terrorism is limited. Inhalation of anthrax has been effectively treated with ciprofloxacin 400 mg administered intravenously every 12 hours. There are no effective therapies for treating patients infected by most of the other viruses that could be used in a bioterrorism attack. For some viruses, a vaccine could be created to stimulate the body's immune system such that the individual may be protected from infection if exposed to the virus at a later date.

JumpSTART Pediatric MCI Triage

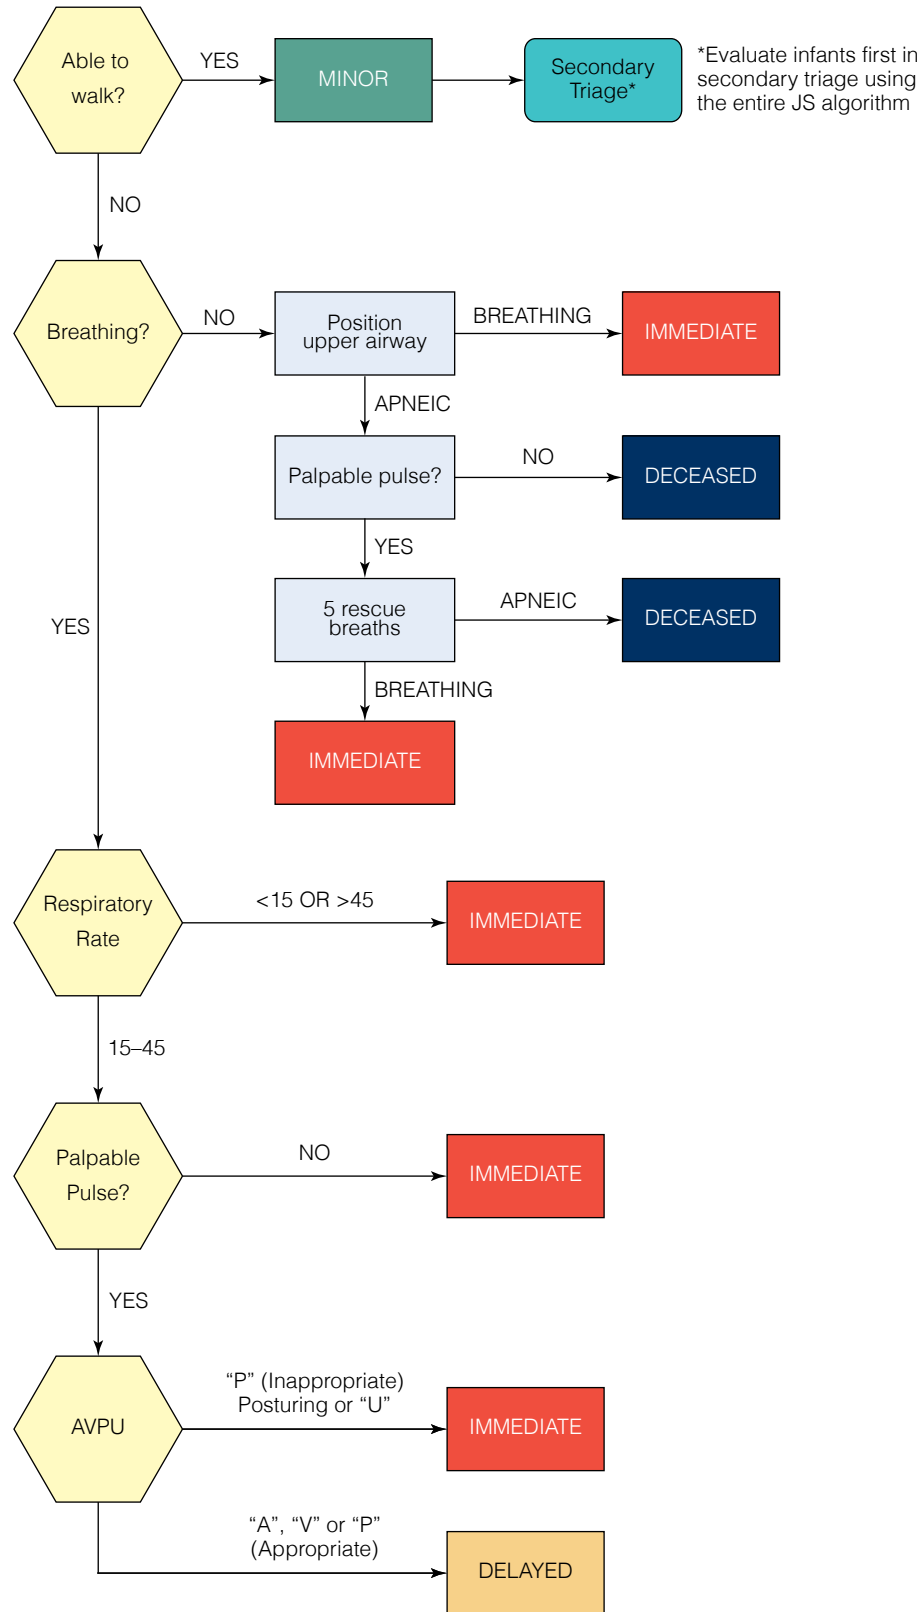

Figure 46-6 >> JumpSTART algorithm for pediatric victims.

Box 46–4

Hot, Warm, and Cold Zones

Hot Zone

The **hot zone** is the most dangerous zone because it is located immediately adjacent to the site of the disaster. All responders who enter the area must be protected by personal protective equipment (PPE) appropriate to the nature of the emergency. Because of the dangers inherent in this location, only the most basic services are performed: Victims are located; basic lifesaving measures are provided (e.g., airways are established and hemorrhages are controlled); antidotes are administered; and the dead and those who cannot be saved are identified. Decontamination of victims is not performed in the hot zone. Survivors are transported to the warm zone for decontamination. All contaminated supplies and equipment are left in the hot zone for collection and disposal at a later date.

Warm Zone

The **warm zone** (also referred to as the yellow, contamination, or contamination reduction zone) is located at least 300 feet from the

outer edge of the hot zone. Although its primary purpose is decontamination, rapid triage and emergency treatment to stabilize survivors may take place in the warm zone. Individuals who have the highest levels of contamination are treated with the highest priority. PPE is required in this zone. After decontamination is completed, victims are moved to the cold zone.

Cold Zone

The **cold zone**, also referred to as the green zone or support zone, is located outside of the warm zone and is the site where decontaminated victims are triaged and treated. It is considered to be comparatively safe, although PPE is still required in case circumstances change (for example, if wind direction shifts). The primary purpose of this zone is to provide medical services and to transport victims who require more than first aid to locations where they will be provided higher levels of service.

The Strategic National Stockpile is a program designed to ensure the immediate availability of essential medical materials to a community in the event of a large-scale chemical or biological attack. Managed jointly by the CDC and the Department of Homeland Security, it consists of large quantities of antibiotics; vaccines; and medical, surgical, and patient support supplies such as bandages, IV equipment, and airway supplies. The first component of the stockpile is a preassembled “push package” designed to meet the community’s needs in the case of an undetermined biological or chemical threat. The push packages are stored in locations that will permit delivery within 12 hours after an attack. The second component is vendor-managed inventory packages that will be shipped once the threat has been clearly identified. These packages are designed to arrive within 24–36 hours.

Collaboration

Emergency preparedness and disaster response depend on the collaboration of an interprofessional healthcare team involving local, state, and federal governmental agencies. Interprofessional training and participation in tabletop exercises, simulations, and mock incidents not only prepare the team members to assume their roles in case of disaster but also provide opportunities for frequent evaluations of the plan. These evaluations lead to a more effective emergency plan and facilitate communications across the interprofessional team that is responsible for the development, implementation, and evaluation of an emergency response plan. Nurses often have contact with members of emergency medical services (EMS) in both emergency departments and disaster situations. A brief overview of the EMS system is presented in **Box 46–5** ».

Lifespan Considerations

Emergency Considerations for Children

After a disaster such as a tornado or hurricane, it is important to keep children safe. Parents need to be aware to

make sure children do not play in or around floodwaters or around drainage ditches or storm drains. It is also important to watch out for live wires or other sources of electricity that can be harmful. Portable generators can pose safety hazards and should always be used outdoors. Children should be kept away from them. Limit the amount of media and news coverage children are exposed to, as this can be frightening to younger children (Healthy-Children.org, 2015).

Emergency Considerations for Older Adults

Older adults are particularly vulnerable to disasters. They often have chronic diseases, which can worsen quickly due to lack of food, water, and extreme heat or cold. Older adults have a greater rate of reliance on medication, oxygen, or other treatments, some of which will require electricity. Many older adults cannot survive long without certain medications or treatments. Older adults may also have limited mobility, diminished sensory awareness, inadequate thermoregulation mechanisms, and social and economic limitations that prevent adequate preparedness and limited their ability to manage during and/or after a disaster hits (CDC, 2016).

Nursing Practice

The role of the nurse in a disaster or emergency will vary based on the type of disaster, its location, the number and condition of the victims, and the personnel (e.g., command staff, first responders, emergency medical technicians, police) and supplies that are available at the time it occurs. Nurses may be called on to perform triage of patients, to perform first aid, or to stabilize patients in preparation for transfer for more advanced care.

Initially, the nurse must decide whether to assist during the disaster or not. This decision will be based on individual safety, family safety and needs, and the greater needs of the

TABLE 46–2 Biological Pathogens of Highest Concern for Bioterrorism Attacks

Pathogen	Cause	Symptoms	Transmission
Anthrax	<i>Bacillus anthracis</i> , a spore-forming bacterium Three types: ■ Cutaneous ■ Respiratory ■ Gastrointestinal	<ul style="list-style-type: none"> ■ Cutaneous: The first symptom is a small sore that becomes a blister, then progresses to a skin ulcer with a black spot in the center. All lesions are painless. ■ Respiratory: <i>Initially</i>: sore throat, mild fever and muscle aches. <i>Later</i>: respiratory symptoms, e.g., cough, chest discomfort, shortness of breath, tiredness and achy muscles. ■ Gastrointestinal: Nausea, loss of appetite, bloody diarrhea, and fever followed by bad stomach pain. 	<ul style="list-style-type: none"> ■ Cutaneous: direct skin contact with spores; often result from handling products, such as wool, from infected animals ■ Respiratory: inhalation of aerosolized spores (rare unless weaponized) ■ Gastrointestinal: eating undercooked meat or dairy products from infected animals (rare)
Botulism	<i>Clostridium botulinum</i> toxin	<p>Foodborne botulism symptoms:</p> <ul style="list-style-type: none"> ■ Usually develop within 12–36 hours after exposure. ■ May include visual effects, e.g., double vision; neurologic symptoms, including slurred speech, dysphagia, and muscle weakness that begins in the shoulders and descends through the body to the calves; and paralysis of the breathing muscles, which, if left untreated, may result in death. 	<ul style="list-style-type: none"> ■ Foodborne: individual ingests preformed toxin. ■ Infant: Occurs in small number of infants who harbor <i>C. botulinum</i> in their intestinal tract. ■ Wound botulism: Occurs when existing wounds are infected with the toxins of <i>C. botulinum</i>.
Plague	<i>Yersinia pestis</i> , a bacterium	<ul style="list-style-type: none"> ■ Pneumonic plague develops within 1–6 days of exposure. ■ Fever, weakness, rapidly developing pneumonia with dyspnea, chest pain, cough, and sometimes bloody or watery sputum 	<ul style="list-style-type: none"> ■ An old mnemonic is “The fleas and lice on rats and mice cause plague.” ■ Bubonic plague is transmitted via an infected flea bite or exposure of broken skin to infected material. ■ Pneumonic plague is of particular interest as a biological weapon because it can be released via weaponized aerosol. It can also be transmitted from individual to individual.
Viral hemorrhagic fevers (VHF)	Several distinct families of zoonotic viruses that reside in an animal reservoir host (e.g., rodent) or arthropod vector (e.g., ticks and mosquitos)	Signs and symptoms, which develop after a 5- to 10-day incubation period, vary by the type of VHF. Early signs and symptoms often include marked fever, fatigue, dizziness, myalgia, weakness, exhaustion, and a rash on the trunk. Severe cases may be accompanied by bleeding under the skin, in internal organs, or from body orifices such as the mouth, eyes, or ears. Patients rarely die from this blood loss. Severe cases may cause shock, nervous system breakdowns, coma, delirium, and seizures. Renal failure may occur in some types of VHF.	<ul style="list-style-type: none"> ■ VHFs are most commonly spread by exposure to an animal reservoir host or arthropod vector. Humans are not natural reservoirs for VHFs; however, some VHFs can be transmitted from individual to individual after an initial human has been infected.
Smallpox	Variola virus	<ul style="list-style-type: none"> ■ During the incubation period (from 7 to 17 days), an infected individual has no symptoms and is not contagious. ■ Prodromal phase (2–4 days) symptoms include a fever of 101°–104°F, head and body aches, and possibly vomiting. This phase may be contagious. ■ The early rash phase is the most contagious period. The rash first appears as spots on the tongue and in the mouth, which then progress into sores that break open, allowing large amounts of the virus to spread into the mouth and throat. The disease is highly contagious during this phase. Within 24 hours the rash, which begins on the face, spreads down and across the entire body. <p>By the third day of the rash, raised bumps develop.</p> <p>By the fourth day of the rash, the bumps fill with thick, opaque fluid and have a depression in the center that resembles a belly button—a distinguishing characteristic of smallpox. Fever increases again.</p> <ul style="list-style-type: none"> ■ Pustular rash (duration of 5 days): Pustular bumps develop (they feel like BBs under the skin), then form a crust and scab over. The scabs fall off, leaving pitted scars. The individual is contagious until all the scabs have fallen off. 	<ul style="list-style-type: none"> ■ Direct and fairly long face-to-face exposure is usually necessary under normal circumstances; however, weaponized smallpox can be spread by aerosol. ■ Direct contact with body fluids or contaminated items such as clothing or bed linen could spread the disease. ■ Humans are the only natural host of variola.
Tularemia	<i>Francisella tularensis</i>	<ul style="list-style-type: none"> ■ Sudden fever, chills, headache, diarrhea, muscle aches, joint pain, dry cough, and progressive weakness ■ If <i>F. tularensis</i> was used as a biological weapon and made airborne for exposure by inhalation, the infected people would experience severe respiratory illness, including life-threatening pneumonia and systemic infection. 	<p>Spread by bacterium found in animals (especially rodents, rabbits, and hares). Means of spread include:</p> <ul style="list-style-type: none"> ■ Being bitten by infected ticks, deerflies, other insects ■ Handling infected animal carcasses and skins ■ Eating or drinking contaminated food or water ■ Inhaling <i>F. tularensis</i>.

Box 46–5

The Emergency Medical Services System

The emergency medical services (EMS) system is a network of resources that provides emergency care and transportation, that is, prehospital care, to victims of illness, injury, or disaster. EMS personnel, who must be trained and licensed, work under the auspices of a medical director, usually a hospital-based physician, who is consulted as needed. There are four levels of EMS professionals.

EMRs and EMTs provide basic life support:

- *Emergency medical responders (EMRs)* provide initial emergency care, including assessment, opening airways, ventilating, controlling bleeding, performing CPR, stabilizing the spine and injured limbs, assisting with childbirth, and aiding other EMS personnel.
- *Emergency medical technicians (EMTs)* do everything EMRs do, but have received additional training and certification. This permits them to assist patients with prescribed medications and give aspirins, NSAIDs, oral glucose, and other medications when indicated.

AEMTs and paramedics are qualified to provide advanced life support:

- *Advanced emergency medical technicians (AEMTs)* have received advanced emergency training so they may start and administer IV fluids; give medications; and assess the need for and provide advanced airway procedures.
- *Paramedics* receive the most training and are qualified to do more in-depth assessments of patients, including the assessment of abnormal heart rhythms, and to perform some invasive procedures.

community at large. Nurses are never expected to jeopardize their own safety or the safety of their families or other rescuers by responding to a disaster. Nurses must also consider whether they have the appropriate skills to respond—that is, whether the skills of the nurse are adequate for the job or whether the job would be better left to individuals with advanced training in disaster response.

If the decision is made to participate, the nurse will follow the emergency preparedness plans created by the employing agency or within the community. The nurse must operate within the defined nursing scope of practice despite the temptation to step outside of those bounds when faced with critical care needs outside the nurse's scope of practice.

Source: Elise Amendola/AP Images.

Figure 46–7 >> EMS personnel and volunteer nurses helped care for hundreds of victims of the Boston Marathon bombings on April 15, 2013.

Individuals who choose to provide care during disasters must be aware of the ethics of doing so and the personal risk that may be involved. The American Nurses Association provides guidance in this area and is working hard to ensure that nurses who work within the framework suggested by ANA are protected from risks associated with providing care.

The injuries experienced during a disaster are specifically related to the type of disaster. For example, nurses working where an earthquake has occurred will treat multiple crush injuries. During the Boston Marathon on April 15, 2013, two explosions occurred. Nurses who had volunteered to provide medical services during the marathon suddenly found themselves in the unexpected position of caring for mass casualties who had sustained fractures, head trauma, severe abdominal injuries, and amputations (**Figure 46–7** >>>).

Nurses should assist their communities not only by providing emergency care during a disaster but also by becoming leaders as their communities prepare for potential disasters by creating or revising emergency preparedness and contingency plans.

REVIEW Emergency Preparedness

RELATE Link the Concepts and Exemplars

Linking the exemplar of emergency preparedness with the concept of professional behaviors:

1. What is the nurse's professional duty in a time of disaster?

Linking the exemplar of emergency preparedness with the concept of managing care:

2. Uninsured Americans are the most vulnerable in the event of a pandemic event. How is early recognition related to access to care?

Linking the exemplar of emergency preparedness with the concept of ethics:

3. What ethical considerations are involved when allocating scarce resources, such as medication, equipment, and healthcare personnel, during a disaster?

REFLECT Apply Your Knowledge

Ed Jones is a 75-year-old retired cabinet maker who makes small toys in the basement of his home, located on the banks of the Deep River. He is independent and a widower. His primary care physician has prescribed antihypertensive medications and monitors his blood pressure regularly. When a week of heavy rainstorms flooded Mr. Jones's neighborhood, his home sustained much water damage and most of his equipment and wood were ruined. Mr. Jones waded through waist-deep water to reach a rescue boat rather than waiting for it to pick him up. The EMTs who triage him decide to transfer him to the nearest emergency department.

You are the nurse assessing Mr. Jones. You observe that he has multiple cuts on his hands that are a result of woodworking and an ulcer on his right foot. Mr. Jones reports that the ulcer developed after

a tool fell on his foot. He adds that he has not sought medical treatment for it. His physical assessment findings reveal: T 100.7°F PO; P 96 beats/min, R 20/min, and BP 178/100 mmHg; his skin is cool and dry with multiple lesions on both hands and a stage II ulcer on his right dorsal foot with yellow-green exudate. His pain rated as 2 on a 0–10 scale with 10 being the worst pain there could be. His lungs are clear, and his heart rate is regular. No edema is noted.

1. What actions did Mr. Jones take that probably exacerbated his skin lesions?
2. What additional information is needed so that you can form nursing diagnoses for Mr. Jones?
3. What nursing diagnoses do you believe would be appropriate?

Module 47

Health Policy

Module Outline and Learning Outcomes

The Concept of Health Policy

Overview of Health Policy

47.1 Describe health policy, as an entity and as a process.

Developing Health Policies

47.2 Summarize the process of developing health policies.

Concepts Related to Health Policy

47.3 Outline the relationship between health policy and other concepts.

Federal, State, Local, and International Agencies

47.4 Outline the agencies or organizations involved in oversight or influence of health policy.

Accrediting Bodies

47.5 Analyze the role of accrediting organizations in the advancement of health policy.

Professional Associations

47.6 Analyze professional organizations' influences on health policy.

Healthcare Funding

47.7 Analyze types of health insurance and the health policies that regulate reimbursement.

Health policies drive the availability, safety, and quality of the healthcare provided in the United States. A poorly constructed policy or the absence of a needed policy can have a significant negative impact on the health and well-being of individuals or whole populations. Professional nurses must understand how healthcare policy affects patients, their own practice, and the organizations in which they work. Every day, nurses see the public's healthcare needs and can envision how new or revised health policies could improve the quality and safety of healthcare. Nurses can influence change by working with public officials at the local, community, state, and national levels as representatives of their professional association or as individual citizens.

Overview of Health Policy

The term **health policy** refers to actions taken by government bodies and other societal actors to attain specific

health-related goals. Health policies include laws, regulations, government agency guidelines, position statements, resolutions, judicial decrees, and budget priorities.

Public health policy is established in **law** (statute) and **regulation** (rules) at the federal or state levels and is therefore enforceable by the government agency responsible for implementing the policy. Public health policy is subject to influence by nongovernmental healthcare organizations and health professions associations, education accreditation agencies, and private citizens. Public health policies have powerful effects on healthcare delivery systems, the health and well-being of U.S. citizens, and professional nursing issues ranging from scope of practice and safe staffing to nursing education funding and universal access to health insurance.

Private agencies may also develop health policy. Policies generated by private associations representing the interests of healthcare organizations, health professions, or health professions education associations are not established in

law or regulation. However, they may have a significant influence, either directly or indirectly, on public policy in the areas of healthcare practice, access, research, funding, and education.

Public healthcare policy is generally first established in law. Lawmaking is the purview of the legislative branch of government. On the federal level, a bill becomes a law when it is passed by votes in both houses of Congress and signed into law by the president. Each state has a similar procedure for passing state laws, which are signed into law by the governor. Presidential vetoes, executive orders, and judicial interpretations of law also have the force of law; courts may determine the outcome of health policy if laws are vague or controversial (Milstead, 2016).

Once a law has been passed, an **executive branch agency** of the federal or state government is responsible for administering it. The Centers for Disease Control and Prevention (CDC), for example, is an executive branch agency authorized to implement laws to protect the public against exposure and spread of highly communicable disease (CDC, 2014). State executive branch agencies include state health departments and state Boards of Nursing. A state health department may have jurisdiction over local health departments and boards of health, sanitarians, and vital statistics, among other responsibilities. Boards of Nursing are authorized to implement the nurse practice act in their state, and license or discipline license holders to protect the public.

Laws provide broad mandates and are written somewhat generally to provide flexibility and so they can withstand the test of time. Therefore, the laws that create public health policy and the laws that create executive branch agencies also give the administering executive branch agencies the authority to write regulations. Regulations provide the detail that describes how the executive branch agency will carry out the law. A regulation must always refer directly to the law it seeks to amplify, and an agency cannot write rules that exceed its statutory authority; the original intent of the legislature that created the law must be honored (**Figure 47-1** >>).

Developing Health Policies

Public healthcare policies are the product of both government processes and political forces. The process often begins when legislators or leaders in executive branch health agencies commit to solve a problem or bridge a gap in services. Sometimes constituents bring problems or gaps to their legislators' attention. In other cases, special interest groups, such as health professions associations, raise awareness and begin to lobby for a new health policy. Some initial questions precede construction of a bill's first draft, such as the following:

- What population of citizens will benefit? Is it large or small? Is it underserved and economically disadvantaged?
- What is the anticipated cost of implementing the policy? Do the benefits outweigh the cost of implementation?
- Who are the stakeholders? Is there support for the policy? If not, what issues are in question?
- Is there a body of scientific evidence to support the efficacy of the policy? Are there similar models in other states that have been successful?

The four major stages in policymaking are agenda setting, government response, implementation, and evaluation. In each stage, formal and informal relationships develop between stakeholders both inside and outside of government. Those serving in government positions can include legislators, bureaucrats such as regulatory officials, the president's or governor's staff, or the courts. Stakeholders outside government can include interested citizens who may or may not be constituents of specific legislators, institutions, and professional associations or other special interest groups.

How resources are allocated, and to whom, is determined within a political framework. Influence, negotiation, bargaining, and compromise are all part of this process, which is not necessarily logical or linear (Milstead, 2016). For example, interested parties may resist certain provisions in a bill midway through the process, which may lead to a revision of the political agenda. An example of developing a health policy is described in **Box 47-1** >>.

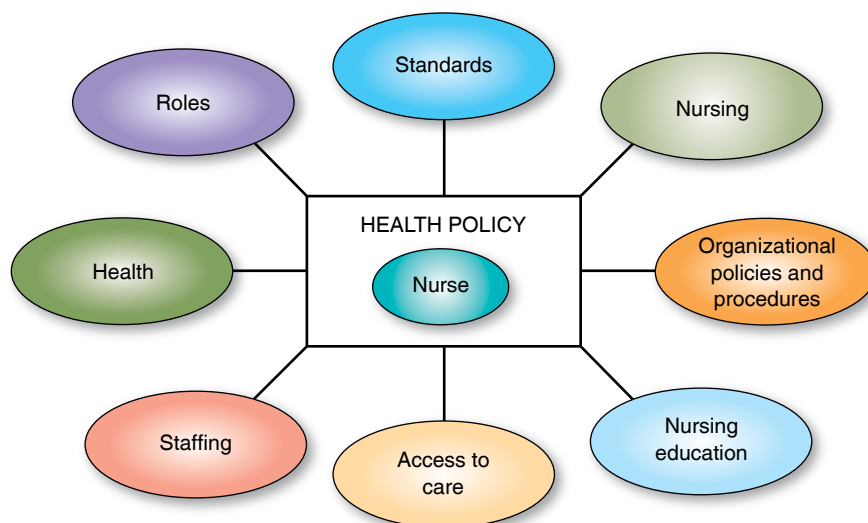

Figure 47-1 >> Why is health policy relevant to nurses?

Box 47–1

Developing an Evidence-informed Health Policy: An Example

Evidence-based practice models provide processes to address clinical problems and improve healthcare outcomes. The same processes can be used to address health policy problems. For example, opioid and heroin abuse is a significant public health problem that has reached epidemic proportions in the United States. A specific issue is that individuals who overdose on opioids are often in respiratory and cardiac arrest when EMS arrives. EMS personnel administer naloxone (Narcan) onsite, but the time between the cardiopulmonary arrest and naloxone administration may be too long to ensure a positive outcome for the individual. The literature demonstrates:

1. Individuals with an opioid addiction are at particularly high risk for overdose immediately post-rehabilitation, when their tolerance has been reduced.
2. Individuals who are most likely to be in the vicinity of the person who is overdosing are family or close friends, who may or may not have emergency medical training, supplies, or equipment.

3. The safety profile on naloxone suggests that it is about as safe for laypeople to administer as is epinephrine during anaphylaxis.

Using an evidence-informed health policy process, policymakers and stakeholders would examine the external evidence (including scientific evidence that naloxone is safe for administration by non-healthcare personnel), combine the evidence with their issue expertise (discussions with and testimony from stakeholders, professional experts, and so on), and combine that with lawmaker and stakeholder values and ethics (e.g., the value of making lifesaving naloxone available to those in a position to administer naloxone when it will be most effective: family and friends of individuals addicted to opioids) (Loversidge, 2016). This process can help to inform the dialogue necessary for the drafting of lifesaving legislation that will permit family and friends of persons addicted to opioids to have a dose of naloxone on hand, the training to administer the drug, and the education to understand the importance of follow-up by calling EMS.

Concepts Related to Health Policy

A number of concepts in the Healthcare Domain relate to health policy. These include accountability, advocacy, ethics, healthcare systems, legal issues, quality improvement, and safety. A few of these integral to health policy are discussed in the Concepts Related to Health Policy feature. They are presented in alphabetical order.

Federal, State, Local, and International Agencies

Agencies with the authority to affect the health of citizens exist at the federal, state, local, and international levels. Their missions and scope of authority differ. Some have a broad scope of responsibility; others have very specific responsibilities. Some have extensive regulatory authority; others receive authority to enact programs from their parent departments.

Federal Agencies

Healthcare policies with direct effects on the nation's health are administered through the U.S. Department of Health and Human Services (HHS) and the agencies it oversees. Other federal departments also administer policies that affect the nation's health. For example, the U.S. Department of Labor oversees policies that affect worker safety; these policies are administered through the Occupational Safety and Health Administration. The U.S. Environmental Protection Agency (2015) is responsible for protecting the environment; this also affects the nation's health.

Department of Health and Human Services

The HHS is the principal federal health agency. It has 11 operating divisions: Administration for Children and

Families (ACF), Administration for Community Living (ACL), Agency for Healthcare Research and Quality (AHRQ), Agency for Toxic Substances and Disease Registry (ATSDR), Centers for Disease Control and Prevention (CDC), Centers for Medicare & Medicaid Services (CMS), Food and Drug Administration (FDA), Health Resources and Services Administration (HRSA), Indian Health Service (IHS), National Institutes of Health (NIH), and Substance Abuse and Mental Health Services Administration (SAMHSA).

HHS is a powerful agency that administers more grant dollars than all other federal agencies combined (HHS, 2017). The 2017 HHS budget of \$1.150 trillion was allocated to fund more than 300 divisions and programs. Examples of HHS programs include those that improve maternal and infant health, protect mental health, promote better nutrition and physical activity, and prevent and manage the impact of infectious and chronic diseases and conditions (HHS, 2017).

» **Stay Current:** To learn more about the programs and services of the U.S. Department of Health and Human Services, go to <http://www.hhs.gov/programs/index.html>.

Occupational Safety and Health Administration

The Occupational Safety and Health Administration (OSHA), an agency of the U.S. Department of Labor, is tasked with ensuring the health and safety of Americans in the workplace. The OSHA legislation covers most private sector employers and their workers plus some employers and workers in the public sector. Part of OSHA's mission is to provide assistance to employers, who are responsible for providing a safe workplace and for reducing or eliminating workplace hazards. OSHA standards address a wide variety

Concepts Related to Health Policy

CONCEPT	RELATIONSHIP TO HEALTH POLICY	NURSING IMPLICATIONS
Healthcare Systems	<p>Access to healthcare is directly related to insurability. The Affordable Care Act changed the profile of insurability for millions of previously uninsured adults and children who would otherwise have been unable to afford healthcare insurance.</p> <p>Public health policies direct coding, billing, and reimbursement for care, which in turn may affect how care is provided and documented.</p>	<ul style="list-style-type: none"> Nurses may find that insured individuals use primary care services more often. Continuity of care may improve for them, especially for individuals with chronic conditions. Health policies related to managed care may have a variety of impacts on patients' healthcare. For example, one patient's health insurance plan may cover brand name prescription medication with a small copayment. A patient on another plan might have a much higher copayment for a brand name prescription; the nurse may need to work with the prescribing provider to ensure that the patient receives a prescription for the more cost-effective generic medication.
Legal Issues	<p>The U.S. Constitution grants states the authority to govern selected professions such as nursing, medicine, and pharmacy. Authority to enforce the laws, known as practice acts, is granted by law, usually to Boards of Nursing, or in some states, to an "umbrella board" that includes a division responsible for oversight of nursing.</p>	<ul style="list-style-type: none"> Current licensure is required for practice as a nurse. Nurses are held accountable for knowing the legal nursing scope of practice in their state and what actions could place their licensure status in jeopardy, as well as all regulations that accompany the nurse practice act. State Boards of Nursing also have authority to write regulations to amplify the practice act. Regulations typically address standards of safe and competent practice, delegation, and continuing education requirements.
Quality Improvement	<p>Some public health policies are enacted to advance science, translate science to practice, and support national health imperatives. The Agency for Healthcare Research and Quality (AHRQ), an agency of the Public Health Service in the U.S. Department of HHS, determines standards of healthcare quality by using a system of quality indicators. If providers are not meeting those standards, AHRQ provides training for health professionals.</p>	<ul style="list-style-type: none"> Nurses are accountable for competent, safe patient care. Part of that responsibility is becoming engaged in organizational quality improvement and quality management projects at the unit level or the organization committee level. Joint Commission–accredited hospitals typically use AHRQ quality indicators specific to their setting, which can provide helpful means to reach The Joint Commission National Patient Safety Goals and other quality improvement objectives.

of hazards in industrial and healthcare workplaces (**Figure 47-2** »). One example is the availability of emergency eye-wash stations (U.S. Department of Labor, n.d.).

» **Stay Current:** Go to www.osha.gov for the latest information from the Occupational Safety and Health Administration.

State Health Agencies

Each state mandates its own health policies and regulations in accord with federal policies and regulations. Each state has its own division or department of health and human services, with a scope of responsibility determined by that state. These departments generally report to the state's governor and are part of the executive branch of state government. State health departments enforce regulation of county health departments and may license or register healthcare facilities such as hospitals and long-term care facilities, child care centers, clinical laboratories, and other service providers such as

Figure 47-2 » OSHA regulations require use of sharps containers for discarding used needles.

Source: A. Ramey/PhotoEdit Inc.

Figure 47-3 » An instructor uses a doll to demonstrate breast-feeding techniques to a group of women in a WIC program.

portable x-ray suppliers. The departments may also be responsible for overseeing the planning and construction of medical facilities and for receiving and resolving complaints about the facilities they regulate. They are often responsible for tracking state health data and statistics; maintaining birth, death, marriage, and divorce records; and enforcing state-wide health laws, such as smoking bans.

State offices of emergency medical services (OEMSs) may be structurally connected to a larger state department, such as a state department of public safety. OEMSs are usually responsible for establishing training and certification standards for EMS personnel, accrediting training programs, overseeing the state's trauma system, and/or licensing medical transportation services. By ensuring that local emergency medical services (EMS) systems comply with the applicable regulations, OEMSs provide citizens access to high-quality emergency medical care.

Local Health Departments

At the county or municipal level, local departments of health administer health policies and offer many vital services to their communities. In counties that surround cities with large populations, both county and city health departments may exist, often with a division of responsibility. For example, the county health department may be responsible for regulating health issues with widespread effects, such as sanitation, retail food establishment safety, and waste disposal. City health departments may provide clinical, environmental, health promotion, and population-based services such as free clinics, sexual health, HIV/AIDS testing, and TB and dental clinics. City health departments are often responsible for developing and enforcing city-wide health codes and for disease monitoring.

Local departments of health may oversee child care center sanitation and food safety and typically offer community-wide disease and injury prevention programs, which may be federally supported or arise in response to local issues. Such programs include injury prevention campaigns, lead poisoning prevention efforts, and making safety equipment such as smoke detectors, children's bicycle helmets, and infant car seats available to families at no cost. Local social

services departments are typically responsible for administering Medicaid, the Child Health Insurance Program, and the Women, Infants, and Children (WIC) supplemental nutrition program, which provides food assistance to pregnant women and children under age 5 who are at risk for malnutrition (**Figure 47-3** »).

Clinical Example A

Richard Taylor is a 46-year-old man who works as an assistant to social workers in a residential homeless shelter in an underserved area of the city. An increasing number of shelter residents have been showing symptoms of active tuberculosis (TB). Social workers have been sending these individuals to the free clinic associated with the shelter for treatment. Now Mr. Taylor and his coworkers have become concerned about their own risk, even though they have taken measures to quickly identify residents at risk and work appropriately with them. Mr. Taylor finds that his city health department does not conduct TB screening, so he seeks screening at a local drugstore with a nurse-managed clinic. He tests positive for TB.

Critical Thinking Questions

1. What information should the nurse practitioner have at hand to assist Mr. Taylor to access low-cost or free treatment?
2. What recommendations could the nurse make to Mr. Taylor to advocate for improved TB risk exposure prevention for employees and residents at the homeless shelter?

International Health Agencies

International health organizations fall into three groups, depending on their funding sources and location: multilateral organizations, bilateral organizations, and nongovernmental organizations (NGOs). All the major multilateral organizations are part of the United Nations (UN). The premier international health organization is the World Health Organization (WHO), which is an intergovernmental agency related to the UN and is the only international health organization with legal authority. Bilateral agencies are governmental agencies with a home in a single country, such as the U.S. Agency for International Development. They provide aid to developing countries. NGOs, also known as private voluntary organizations (PVOs), are independent of any government. More than 130 health-related NGOs based in the United States were reported in 2013; of these, 20 were faith-based (Moss, 2014). An example is Project Hope, which provides essential medicine and supplies, volunteers, medical training, and disaster response. International health organizations typically provide support services and establish guiding policy.

Accrediting Bodies

Accreditation is a process of gaining recognition through a peer review process that evaluates the quality of an organization on the basis of the standards and criteria of the accreditation organization. Reputable accreditation organizations establish standards using a rigorous process based on evidence. Whereas state or federal licensing or certification is governmental, accreditation is private and voluntary; but achieving accreditation certifies that the organization meets quality criteria and is competent to provide the services or programs it offers. Accredited organizations must

be reevaluated at intervals specified by the accrediting body. To achieve reaccreditation, an organization must provide evidence that it has continuously evaluated its own performance, has acted to correct deficiencies and continuously improved its performance, and continues to meet the accreditation standards.

The accreditation body conducts an on-site survey to validate the organization's self-assessment and performance and to determine whether the organization meets the required standards. This occurs at the initial accreditation visit and during periodic reaccreditation visits. Benefits of accreditation and the nurse's role in the process depend on the type of accreditation.

The Joint Commission

The Joint Commission is an independent, nonprofit organization that sets standards for and accredits healthcare provider organizations, such as ambulatory care centers, behavioral healthcare providers, hospitals, and long-term care facilities. Its standards address key functions for each type of organization it accredits—for example, infection prevention and control, provision of care, treatment and services, medical management, environment of care, and performance improvement (The Joint Commission, 2016). Healthcare organizations are highly motivated to achieve Joint Commission accreditation, which brings not only greater consumer trust and respectability, but also credibility with private third-party payers, and helps organizations meet qualifications for Medicare and Medicaid reimbursement.

Although The Joint Commission is an independent, non-governmental organization, its work significantly influences national quality and safety standards and the advancement of healthcare policy. For example, since 2003, The Joint Commission has identified annual National Patient Safety Goals (NPSGs) (see the module on Safety) to help accredited organizations address specific patient safety concerns (The Joint Commission, 2015). The Joint Commission also has requirements for reporting sentinel events (see the module on Quality Improvement). The NPSGs and the Sentinel Event reporting system provide benchmarks for quality improvement processes in healthcare organizations across the country.

A nurse's role in The Joint Commission accreditation process may include helping to develop, revise, or facilitate use of policies and procedures for nursing practice that are current and evidence-based. The nurse may also participate in an organization's self-review activities. Nurses, especially those in management positions, may also be part of meetings with the accreditation survey team; survey teams are often interested in speaking with the healthcare providers who are most involved in maintaining standards at the point of care.

» **Stay Current:** Go to www.jointcommission.org for the latest information from The Joint Commission.

Clinical Example B

Darren Langdon is a 34-year-old staff RN on a medical–surgical unit in a hospital classified by The Joint Commission as a Critical Access Hospital. The nursing department has been preparing for a Joint Commission reaccreditation survey visit. Unrelated to the visit, Darren's unit has been concerned about the rate of catheter-associated urinary tract infections (CAUTI). Darren has taken the lead in gathering data about the CAUTI

rates on his unit compared to other units over the past 6 months, has done a review of the hospital's policies and procedures, has talked to the nurses on his unit about how they implement these, and has conducted a review of the current literature on CAUTI. Having learned that the current hospital policy is outdated in comparison to what he found in the literature, Darren has been encouraged by the nurse manager, his fellow staff members, and nursing leadership to draft a new policy to present to the hospital's policy and procedure committee.

The Joint Commission survey visitors come to Darren's unit during a reaccreditation survey visit. They have noticed the data on the CAUTI rates and are asking the nurse manager and staff to respond to questions about possible causes and actions. Darren's nurse manager asks him to meet with her and the visitors to discuss the unit's process and plan to address the CAUTI rates, at both the unit and organizational levels.

Critical Thinking Questions

1. What should Darren be aware of with regard to the National Patient Safety Goals? Is there a National Patient Safety Goal related to CAUTI?
2. How should Darren explain to the survey visitors the process he used to address the CAUTI problem on his unit?

Nursing Education Program Accreditation

Although nursing program accreditation is considered voluntary, most graduate nursing programs and many RN-to-BSN programs require applicants to graduate from an accredited prelicensure/BSN program as a criterion for admission. The Commission on Collegiate Nursing Education (CCNE), an autonomous arm of the American Association of Colleges of Nursing (AACN), accredits baccalaureate and graduate education programs. The Accreditation Commission for Education in Nursing (ACEN) accredits all types of nursing education programs (clinical doctorate, master's degree, baccalaureate degree, associate degree, diploma, and practical nursing education programs). The National League for Nursing Commission for Nursing Education Accreditation (NLN CNEA) was established in 2013. In the spring of 2016, the NLN CNEA issued standards of accreditation for practical nursing/vocational nursing, diploma, associate, bachelor, master's, and clinical doctorate degree programs. CNEA is an autonomous accreditation division of NLN (NLN, 2016a).

Many accrediting organizations belong to the Association of Specialized and Professional Accreditors (ASPA). The ASPA Code of Good Practice for Accrediting Bodies, which has been adopted by CCNE, states that accrediting organizations focus on educational quality, “not narrow interests, or political action” (AACN, 2016a). By conforming to this ethical principal and focusing on education quality, nursing education accreditation commissions also work toward improving the quality of nursing education and healthcare by influencing educators and the membership of their parent or affiliate organizations. AACN, the national voice for baccalaureate and graduate nursing education, has a Government Affairs division that oversees its federal policy agenda. AACN's policy agenda focuses on expanding federal funding streams to support nursing education; supporting higher education policy priorities that affect affordability, access, transparency, and diversity; and advancing federal initiatives relevant to nursing education (AACN, 2016b).

Professional Associations

Nursing associations exist to serve their specialized membership and advance the nursing profession. Professional nursing associations define standards of practice and professional behaviors, establish codes of ethics for their members, support nursing research, and participate in policy development at a level commensurate with the scope of their membership. Some associations are state branches of the national association representing all registered nurses; others serve one of the many specialized memberships.

International Council of Nurses

The International Council of Nurses (ICN), which represents more than 16 million nurses worldwide, is the world's oldest organization for health professionals. It is a federation of more than 130 national nurses' associations with the mission to "represent nursing worldwide, advancing the profession and influencing health policy" (ICN, 2015). The ICN addressed a number of key issues for nursing at the 69th World Health Assembly in Geneva, Switzerland. These included the ICN's commitment to work with world government leaders to implement an action plan to address violence as the first point of care for elder abuse and intimate partner violence and in conflict, post-conflict, and humanitarian settings. Another issue identified was the need to remove regulatory barriers on nursing scopes of practice to strengthen primary healthcare systems as a key to improving elder well-being (ICN, 2016).

Sigma Theta Tau International

Sigma Theta Tau International (STTI) is an international nursing organization with more than 135,000 active members in 500 chapters in 90 countries around the globe. It was founded in the United States in 1922 and incorporated as an international organization in 1985. Its mission is "advancing world health and celebrating nursing excellence in scholarship, leadership, and service" (STTI, 2016). Membership is by invitation to baccalaureate and graduate nursing students who demonstrate excellence in scholarship and to nurse leaders who exhibit exceptional achievements in nursing. STTI's benefits to its members include leadership summits, funding and forums for disseminating research, continuing education opportunities, and career services. STTI's Global Health Policy Position Statement states that "the membership is engaged in education, clinical practice and leadership endeavors that inform health policy at local, national, and international levels" (STTI, n.d.). Other STTI Position Statements that have policy implications include topics such as international nurse migration, global health and nursing research priorities, and universal access to affordable, high-quality healthcare.

American Nurses Association

The American Nurses Association (ANA) represents the 3.6 million registered nurses in the United States through joint membership with its constituent and state nurses' associations and direct membership in ANA. Its mission statement is "Nurses advancing our profession to improve health for all" (ANA, n.d.). The ANA fosters high standards of nursing practice, promotes the rights of nurses in the workplace, projects a positive and realistic view of nursing, and lobbies Congress

and federal regulatory agencies on healthcare issues affecting nurses and the health of Americans. There are constituent or state nurses' associations in each of the 50 states and in Guam, the Virgin Islands, and Washington, DC, as well as the Federal Nurses Association (ANA, 2016a). Membership for the Federal Nurses Association is open to registered nurses who are classified as active duty in the U.S. armed forces: Army, Navy, Air Force, or U.S. Public Health Service.

The ANA Membership Assembly and/or Board of Directors respond to current events related to the ANA's policy agenda by writing a position statement or resolution. ANA Position Statement topics include specific issues related to bloodborne and airborne diseases, consumer advocacy, drug and alcohol abuse, environmental health, and ethics and human rights. The ANA also writes issue briefs expressing the association's opinion on how federal or state laws or proposed federal rules, regulations, policies or guidelines affect nurses and patients (ANA, 2016b). In addition, the ANA publishes a number of documents that serve as guiding principles and standards for all RNs in the United States.

» **Stay Current:** Go to www.nursingworld.org for more about the American Nurses Association.

National Student Nurses Association

The National Student Nurses Association (NSNA) is a non-profit organization that mentors nursing students preparing for initial licensing as registered nurses. Students may be enrolled in associate, baccalaureate, diploma, and prelicensure (second-degree) graduate programs. NSNA is dedicated to fostering the professional development of these students by conveying "the standards, ethics, and skills students will need as responsible and accountable leaders and members of the profession" (NSNA, n.d.). NSNA membership provides opportunities for workshop participation, networking, scholarships, and career planning. NSNA also links interested members to the ANA Nursing Strategic Action Team (N-STAT program), which unites nurses across the nation who aspire to let lawmakers know their position on bills moving through Congress.

Specialty Practice Nursing Associations

Most nursing specialties are supported by a professional specialty practice association, which advances nursing practice in the affiliated specialty area and provides support to practitioners and their patients. The missions of the organizations include advocacy, education, provision of networking opportunities, and strengthening professional identities among members. Examples of specialty practice associations include the Academy of Medical-Surgical Nurses; the American Assisted Living Nurses Association; the American Association of Critical-Care Nurses; the Association of Pediatric Oncology Nurses; the Association of Women's Health, Obstetric, and Neonatal Nurses; the National Association of Orthopaedic Nurses; and the Oncology Nursing Society.

Several professional nursing associations exist to support and promote the interests of special nursing profession demographics. These include the Asian American/Pacific Islander Nurses Association, the American Assembly for Men in Nursing, the National Black Nurses Association, and the National Association of Hispanic Nurses.

Clinical Example C

Marsha Johnson, RN, BSN, graduated from a university college of nursing 10 years ago. Three years ago, she decided to continue her education and applied to an accredited certified registered nurse anesthetist (CRNA) program. She completed the program, passed the national certification exam, and was hired by a small-volume ambulatory surgery center. She competently delivers care and enjoys her advanced practice role. She works with an anesthesiologist but is the only CRNA on staff. She recently realized that as a nurse anesthetist, she has a limited number of professional contacts with other nurses employed at the center and that because the surgery center requires only one nurse anesthetist, she will not have many opportunities for interaction with peers or on-site educational opportunities specific to her role. She is starting to feel isolated.

Critical Thinking Questions

1. What professional association would you recommend to Ms. Johnson to fulfill her need for peers and CRNA-specific continuing education?
2. What networking and support is available from this association?
3. Where else could Ms. Johnson go for professional support?

National League for Nursing

The National League for Nursing (NLN), the first nursing organization in the United States, was founded in 1893 as the American Society of Superintendents of Training Schools for Nurses. The NLN's mission is "to promote excellence in nursing education to build a strong and diverse nursing workforce to advance the health of our nation and the global community" (NLN, 2016b). Its membership consists of nursing education programs, nursing faculty, and leaders in nursing education, both nurses and non-nurses. NLN nursing education program membership includes practical nursing, associate degree, baccalaureate, master's, and doctoral programs. Member services include professional development, research, student exam services, nurse educator certification, public policy, and networking (NLN, 2016c). The organization's public policy focuses on influencing policies affecting nursing workforce development, nursing education, and healthcare for underserved populations (NLN, 2015).

The American Association of Colleges of Nursing

The American Association of Colleges of Nursing (AACN) is "the national voice for America's baccalaureate and graduate nursing education" (AACN, 2016c). Its membership consists of 790 member schools of nursing, which includes baccalaureate, graduate, and postgraduate programs. AACN serves the school of nursing administrative staff, faculty, and students. It facilitates programs in instructional development, research, organizational leadership, faculty practice, and other services. AACN establishes *Essentials*, which are the standards for the education curricula of its member nursing programs. AACN's government relations team works to advance public policy related to nursing education, research, and practice. AACN has served as a leader in securing federal support for nursing education and research and has helped shape policy affecting nursing education programs and financial assistance for nursing students (AACN, 2016c).

Healthcare Funding

Perhaps the most important issue in health policy today is how healthcare is funded. Healthcare has historically been considered a market-based commodity in the United States. The sweeping social welfare legislation embodied in the Social Security Act of 1935 did not include healthcare coverage for all Americans. Blue Cross and Blue Shield, the earliest private insurance plans, were developed in the early 1930s and covered hospital and physician care. With the advent of private insurance, the political pressure to enact government-operated health insurance was diffused. No progress was made on this issue until 1965, when the federal government entered healthcare financing with Medicare and Medicaid (Pulcini & Hart, 2014).

Health insurance in the United States is available through private insurance companies and through government-funded programs for those who qualify. As part of the Affordable Care Act (ACA) passed by Congress in 2010, many individuals who did not qualify for Medicare or Medicaid and who would otherwise not have had access to health insurance gained improved access to health insurance coverage. Access to health insurance for individuals who do not qualify for Medicare or Medicaid or who do not have employer-based health insurance coverage varies from state to state and depends on policies enacted by state legislatures and Congress.

Private Healthcare System

Any health insurance not funded by government is private health insurance. Individuals purchase private health insurance plans to protect themselves from all or some of the medical, surgical, and preventive care expenses they would incur without coverage. The three basic private insurance plan types are employer-sponsored insurance, self-employment-based plans, and direct-purchase plans. There are also private insurance policies to supplement Medicare coverage.

Employment-sponsored insurance (ESI) is offered through one's employer or union. The percentage of adult Americans under 65 who subscribe to this type of health insurance fell from 69.7% in 2000 to 59.5% in 2011 (Robert Wood Johnson Foundation, 2013). Group health insurance is usually purchased by large employers that offer healthcare coverage to eligible company employees. ESI coverage may be extended to include the spouse, dependents, or domestic partner of the employee. A **domestic partner** is an unmarried partner of the same or opposite sex. Group coverage may also be purchased through voluntary and membership associations, such as professional and trade groups, bar associations, local chambers of commerce, and AARP. Benefits of group health insurance, especially when provided by large employers, may include lower premium costs (the amount of money paid for insurance coverage) and better coverage for eligible employees and their families. The employer may pay nothing toward the premium or may make partial or full payment; the employee is responsible for the premium amount not paid by the employer. The insured may also be responsible for additional costs such as deductibles, coinsurance, and copayments. Deductibles are commonly between \$100 and \$300 per individual and \$500 to \$2000 per family annually for medical care. A **copayment** is a set amount paid at the time of service (e.g., \$20 for a

primary-care physician office visit). Copayments for specialty care are usually higher than those for primary care. An out-of-pocket maximum protects the patient from catastrophic healthcare costs; if medical expenses reach a certain amount during a 12-month period, the plan covers all usual and customary fees for the remainder of the year.

Self-employment-based health insurance coverage is available only to individuals who are self-employed, and only the policyholder is covered by the plan. Individuals who are self-employed and have chronic health conditions often experience difficulty trying to purchase health insurance through private insurers.

An individual who needs private health insurance and is ineligible for group coverage purchases an individual policy. The individual purchasing an individual plan is responsible for paying the premium as well as copayments and deductibles. Individual health insurance policies are usually more expensive and coverage is more restricted than under group health coverage. A medical examination may be required to determine eligibility, and individuals with pre-existing medical conditions may find it difficult to find a company that will provide health insurance.

Types of Private Health Insurance Plans

Health insurance plans offered in the United States range from health maintenance organizations (HMOs), the most restrictive type, to indemnity plans (also known as “fee-for-service” plans), the least restrictive. Plans in the middle of the spectrum are point-of-service (POS) plans and preferred provider organizations (PPOs); both are considered managed-care plans and include features of both HMO and indemnity coverage. Usually, a greater selection of in-network providers is available in PPO and POS options than in HMOs.

Health maintenance organizations (HMOs) are insurance plans that limit coverage to care from physicians who contract with the specific HMO. Out-of-network care is not generally covered except in emergencies. HMOs may require that the person live or work in the service area. Participants must often select a **primary care provider (PCP)**, who serves as the gatekeeper to care and refers the patient to in-network hospitals and specialists when additional care is needed. HMOs typically provide a broad range of healthcare benefits; they often provide integrated care, covering preventive care and wellness.

A **preferred-provider organization (PPO)** does not require the insured to select a PCP. PPOs usually have larger networks of providers than HMOs and provide financial incentives that encourage insured persons to seek care from in-network providers. PPOs are less restrictive than HMOs but typically have higher copayments.

A **point-of-service (POS) plan** is a hybrid of an HMO and a PPO. Each time insured individuals seek healthcare, they decide which option—HMO or PPO—to use. Members pay less if they use in-network physicians, hospitals, and other healthcare providers. If they opt to use out-of-network providers, they pay higher copayments, coinsurance, and deductibles. The advantages of the POS plan are its flexibility and freedom of choice in comparison with a traditional HMO.

Indemnity plans allow the insured to self-select healthcare providers; that is, there is no network. These plans may use some managed-care techniques to control costs (e.g., preauthorization of MRIs).

The **consumer-driven healthcare plan (CDHP)** is a type of employer-sponsored coverage that combines a private insurance plan with a health savings account (HSA) or health reimbursement account (HRA). This type of plan typically has a higher deductible but lower monthly premiums. As part of the plan, the employer offers HSA or HRA accounts to all employees. Employees then save money in the HSA or HRA so that they can pay for deductibles and noncovered services. In some cases, the amount that goes into the HSA or HRA is provided by the employer as part of the employee benefits package.

Medigap Policy

A **Medigap policy** (i.e., Medicare supplemental insurance) is private health insurance designed to supplement Medicare coverage. These policies may pay copayments, coinsurance, deductibles, and “gaps” in Medicare coverage (i.e., noncovered health care costs). If an individual has a Medigap policy, Medicare will pay its share first; then the Medigap policy will pay its share. Medigap policies are required to comply with federal and state laws and must be transparent in stating they are “Medicare Supplement Insurance.” State laws designate the letters by which these policies can identify themselves.

Federally Funded Public Healthcare

The Centers for Medicare and Medicaid Services (CMS) is the federal agency and public funding system responsible for administering Medicare, Medicaid, and the Children’s Health Insurance Program (CHIP). Other public funding systems include the Veteran’s Administration (VA); the Defense Health Program (TRICARE) for military personnel, their families, and military retirees; the Indian Health Service, which covers American Indians and Alaskan Natives; and the Federal Employees Health Benefits (FEHB) Program, which covers federal employees. Federally funded healthcare is subject to relevant federal legislation.

Medicare

Medicare is a federally funded health insurance program available to people age 65 or older who have worked in a Medicare-covered employment setting, younger people with disabilities, and people with end-stage renal disease or amyotrophic lateral sclerosis (ALS). Medicare covers 16% of Americans (Kaiser Family Foundation, 2012). Four types of coverage are available through Medicare (**Box 47-2** >>>).

Medicare does not cover all medical expenses. Excluded services include long-term care, routine dental and eye care, hearing aids and the exams for fitting them, and cosmetic surgery. People often purchase Medigap policies from private companies to supplement or fill in the gaps in their Medicare coverage.

>> **Stay Current:** For additional information about CMS and its programs, visit <http://www.cms.hhs.gov>

Programs Financed at the Federal, State, and Local Levels

Medicaid

Medicaid was established in 1965 under Title 19 of the Social Security Act. It is available to certain lower-income individuals and families, the elderly, and people with disabilities who

Box 47–2

The Different Parts of Medicare

Medicare Part A (Hospital Insurance)

- Helps to cover inpatient care in hospitals.
- Helps to cover home healthcare and care in skilled nursing facilities and hospice.
- The covered individual must be age 65 or older, and either the individual or the individual's spouse must have been employed in a Medicare-covered employment setting and paid Medicare taxes for at least 10 years. Copayments, coinsurance, or deductibles may apply.

Medicare Part B (Medical Insurance)

- Helps to cover medically necessary services provided by physicians and other healthcare providers, outpatient care, home healthcare, and durable medical equipment.
- Coverage includes partial payment for office visits to physicians and other healthcare providers; outpatient services, including screening exams such as mammograms and colonoscopies; and preventive services such as flu shots.
- All individuals covered by Medicare Part B pay an annual deductible and a 20% copayment; the remaining covered costs are paid by Medicare.

Medicare Part C (Medicare Advantage Plans)

- A health coverage option run by private insurance companies approved by and under contract with Medicare.
- Includes all services covered under Parts A and B, usually includes Plan D prescription drug coverage, and may cover other services such as hearing and vision testing.
- Medicare pays the insurer for each individual enrolled in the plan. The insured must cover out-of-pocket expenses, including the Part B premium, an additional premium to the company providing the coverage, and applicable copayments.

Medicare Part D (Medicare Prescription Drug Coverage)

- A prescription drug option run by private insurance companies, such as HMOs and PPOs, approved by and under contract with Medicare.
- May help lower prescription drug costs and help protect against higher costs in the future.

Source: Data from Centers for Medicare and Medicaid Services. (2016). *Medicare and You 2016*. Retrieved from www.medicare.gov

meet the eligibility requirements. Medicaid is jointly funded and administered by states and the federal government. Each state sets its own guidelines regarding eligibility and covered services, which are then matched by federal funding. Federal mandates require coverage of certain services (e.g., hospitalization, physician services, laboratory services, radiology studies, preventive services, prenatal care, nursing home and home health services, and medically necessary transportation). The federal match enables states to ensure comprehensive health coverage for as many of their residents as possible (Pulcini & Hart, 2014). In 2014, the ACA changed the Medicaid eligibility requirements to allow more people to qualify. Also, the ACA offers additional community-based care programs as an alternative to nursing home care.

Supplemental Security Income

Supplemental Security Income (SSI) is a federal and state public assistance program funded by general taxes. SSI is designed to help aged, blind, and disabled people who have little or no income, including children who are blind and disabled. It provides cash for basic needs such as food, clothing, and housing.

Children's Health Insurance Program

Federal and matching state funding combine to provide the **Children's Health Insurance Program (CHIP)**, previously known as the State Child Health Insurance Program (SCHIP). CHIP provides health insurance coverage to children under the age of 19 whose families earn more than the Medicaid limits but cannot afford to purchase private healthcare coverage. Within broad federal guidelines, each state determines the design of its program, eligibility requirements, benefit

packages, payment levels for coverage, and administrative and operating procedures. Federal requirements mandate that states include routine checkups, immunizations, dental and vision care, inpatient and outpatient hospital care, and laboratory and x-ray services in their benefits.

State-funded Healthcare

State governments may administer programs targeting specific public health priorities, which are funded by either states or localities, frequently in combination with federal grants. Examples include maternal and child health, smoking cessation, obesity prevention, HIV/AIDS, substance abuse, and environmental health. In addition, state governments have a degree of responsibility for oversight related to the regulation of health insurance, healthcare providers, and public health activities (Pulcini & Hart, 2014).

Local/County Level Healthcare

In many states, local and county governments may fund public health initiatives or programs. Some local governments fund indigent care by subsidizing and running public hospitals and clinics. Two examples are New York City's Health and Hospital's Corporation, and Chicago's Cook County Hospital. These hospitals, which serve individuals regardless of their ability to pay, also receive a large amount of operating money from Medicaid and Medicare. Therefore, health policy at the federal and local/county levels plays a part in shaping the funding models for these subsidized institutions.

The Affordable Care Act

From the beginning, the ACA met with controversy and troubled implementation (see the Focus on Diversity and

Focus on Diversity and Culture

Implementing the Affordable Care Act

To be fully effective, even a health policy crafted to address health-care disparities may need significant overhaul either in the original language or in the implementation by federal or state agencies. The first state to implement the ACA was California, a state with a very diverse population. A study found major issues associated with its early implementation. For instance, racial disparities in enrollment were found. At the end of the enrollment period in April 2014, the percentage of new White enrollees was 7.4% higher than that of Latinos, 14% higher than that of Asian-Pacific Islanders, and more than 12 times higher than that of African Americans.

Two factors were cited for this trend. The first was that Latinos and African Americans had internet access at less than half the rate of Whites. In addition, general website difficulties and failures on the Spanish language website were cited as issues. Also, the

combination of language, fear of legal reprisal against undocumented immigrants, and unfamiliarity with both medical and insurance terms served as obstacles. Another issue the study established was that the e-verify system was set up for middle-class individuals with standard credit profiles and with access to the internet and email. The study also found that the process was not immigrant-friendly.

Despite its initial implementation difficulties, the ACA did improve access to healthcare. However, it did not make healthcare affordable for many Californians. For example, a seasonal construction worker said that his coverage minimum would have been \$240 a month, with an additional premium to add his daughter. He simply did not have the money, so he did not apply (Alliance for a Just Society, 2015).

Source: Based on Alliance for a Just Society. (2015). *Report on Breaking Barriers (Obamacare) in California*. Retrieved from http://allianceforajustsociety.org/wp-content/uploads/2015/04/BBReport_CALIF.pdf

Culture feature). However, as of January 2017, more than 20 million previously uninsured individuals had gained health-care insurance coverage through the provisions of the Affordable Care Act (Greenberg, 2017; Levey, 2017). Between 2013 and 2014, the uninsured rate dropped from 16.2% to 12.1% (Kaiser Family Foundation, 2016). As with any government-funded program, ACA came with a tax burden. The taxpayers' share of U.S. health expenditures for 2013 has been estimated to be \$1.877 trillion; this is an estimated 64.3% of national health expenditures in that year. This figure is projected to increase to \$3.624 trillion in 2024 (Himmelstein & Woolhandler, 2016).

The ACA included a number of provisions that reformed the health insurance market. These included measures to

ensure that consumers receive value for the cost of their premiums, restricts insurers from charging unreasonable health insurance premiums, and hold insurance companies accountable for unjustified premium increases. In addition, the ACA banned annual dollar limits on essential coverage such as hospitals, physician, and pharmacy benefits; required that children of the insured be covered until they turn 26 years old; required new health plans to cover certain evidence-based preventive services and eliminate cost sharing for those services; and made it possible for Americans with preexisting conditions to gain and keep their coverage. The ACA included many additional provisions that benefits the consumer and requires health insurers to provide fair, equitable coverage and transparency of information.

REVIEW The Concept of Health Policy

RELATE Link the Concepts

Linking the concept of health policy with the concept of ethics:

1. How does enacting evidence-based policies or legislation align with ethical standards of nursing?
2. Which federal law protects patient privacy?

Linking the concept of health policy with the concept of legal issues:

3. Explore the board of nursing website in your state, and find the section of law or rules related to the nurse's accountability for patient care and safety. What nursing actions or protective measures promote compliance with those sections of law or rule?

Linking the concept of health policy with the concept of safety:

4. Review The Joint Commission National Patient Safety Goals. Choose one that is relevant to a clinical area in which you have recently had experience. What nursing actions could you take to ensure that the NPSG is met?

REFER Go to Pearson MyLab Nursing and eText

- Additional review materials

REFLECT Apply Your Knowledge

Emma Jones is a 29-year-old woman who works for a small manufacturing firm. The demand for the firm's product has grown. To keep pace with the orders, the manufacturer bought some used equipment and hired more people, but the used equipment is noisier and less efficient than newer models. Ms. Jones visits the ear, nose, and throat clinic with a chief complaint of persistent ringing in her ears. As she provides her history, she and the nurse realize that the ringing began a week after the additional equipment was put into use. The ear protection that is available has to be shared because of the influx of new employees. This means that Ms. Jones and the other employees must rotate wearing ear protection. The supervisor has not yet purchased additional ear protection, and employees lack ear protection for about one quarter of their work shift.

1. What is the employer's responsibility for protecting his employees' hearing health?
2. What options does an employee have if the employer does not fulfill this responsibility?
3. As the nurse at the clinic, what could you do to advocate for a safer workplace for Ms. Jones and her fellow employees?

Module 48

Informatics

Module Outline and Learning Outcomes

The Concept of Informatics

Nursing Informatics

48.1 Analyze informatics as a key component of nursing practice.

Concepts Related to Informatics

48.2 Outline the relationship between informatics and other concepts.

Healthcare Information Systems

48.3 Explain the use of informatics in healthcare.

Computerized Medical Records

48.4 Analyze the uses of computerized medical records.

Telehealth

48.5 Analyze the use of informatics for telehealth.

Geographic Information Systems

48.6 Explain the use of geographic information systems.

Patient Education and E-Health

48.7 Analyze the use of the internet for patient education and e-health.

Ergonomic Considerations

48.8 Differentiate good ergonomics from poor ergonomics.

Informatics Exemplars

Exemplar 48.A Clinical Decision Support Systems

48.A Analyze clinical decision support systems as they relate to informatics.

Exemplar 48.B Individual Information at Point of Care

48.B Analyze individual information at point of care as it relates to informatics.

Today's healthcare professionals handle extraordinary amounts of information. At the bedside and in the examination room, nurses and other clinicians assess patients' health status and prioritize and provide care. Each action creates new data that must be recorded and used at different points of service from direct care to billing related to the cost of that care. In today's clinical environment, that information is created, stored, and accessed with the help of technology. **Biomedical informatics** is the "interdisciplinary science that deals with biomedical information, its structure, acquisition and use. Biomedical informatics is grounded in the principles of computer science, information science, cognitive science, social science, and engineering, as well as the clinical and basic sciences" (Vanderbilt University School of Medicine, 2013).

Nursing Informatics

The relationship between nursing and informatics is so critical that the American Nurses Association (ANA) recognized nursing informatics as a specialty in 1992, and the American Nurses Credentialing Center began offering board certification for nursing informatics in 1995. The ANA defines **nursing informatics (NI)** as

the specialty that integrates nursing science with multiple information management and analytical sciences to identify, define, manage, and communicate data, information, knowledge, and wisdom in nursing practice. NI supports nurses, consumers, patients, the

interprofessional healthcare team, and other stakeholders in their decision-making in all roles and settings to achieve desired outcomes. This support is accomplished through the use of information structures, information processes, and information technology (ANA, 2015).

The nursing section of the American Medical Informatics Association (AMIA) defines nursing informatics as the

science and practice (that) integrates nursing, its information and knowledge, with information and communication technologies to promote the health of people, families, and communities worldwide (AMIA adapted from IMIA Special Interest Group on Nursing Informatics, 2016).

Even in the few practices that do not yet use electronic health records (EHRs), nurses use technology every day: Cardiac monitors, mechanical ventilators, and many blood pressure cuffs use computer technology, as do most telephone systems. Informatics is an everyday occurrence in the practice of nursing.

Informatics and Health Policy

Both professional organizations and government entities recognize and support the careful, purposeful implementation of informatics in healthcare environments. The Healthcare Information and Management Systems Society (HIMSS) works to improve healthcare quality, safety, and outcomes through improving the use of information technology (IT) and systems. HIMSS is a nonprofit organization with both individual and corporate members. The American Medical Informatics Association (AMIA) is another organization dedicated to the development and application of health informatics to support patient care and teaching. The Alliance for Nursing Informatics (ANI) works to support and advance the areas of informatics leadership, practice, education, policy, and research. It works closely with other organizations such as HIMSS and AIMIA. These groups promote the use of health IT and sponsor conferences as well as policy development. The Technology Informatics Guiding Educational Reform (TIGER) initiative focuses on integrating technology and informatics competencies into nursing education as well as practice. The TIGER initiative is currently integrated into the HIMSS network.

>> Stay Current: For more information about the TIGER initiative, visit <http://www.himss.org/professionaldevelopment/tiger-initiative>.

The administrations of both President George W. Bush and President Barack Obama contributed to the use of informatics in the delivery of healthcare across the United States. Electronic medical documentation is thought to help reduce errors, reduce healthcare costs, and improve the quality of care delivered to patients. The Bush administration introduced a policy that, over the course of 10 years, would encourage the use of electronic documentation of the healthcare record. The Obama administration took this policy further with the introduction of the American Recovery and Reinvestment Act of 2009 (ARRA), which provided \$27 billion worth of incentives to healthcare providers to promote the use of electronic medical records. Through the Health

Information Technology for Economic and Clinical Health Act (HITECH), the funding is directed toward EHRs. The Centers for Medicare and Medicaid Services (CMS) and the Office of the National Coordinator for Health Information Technology (ONC) are charged with the oversight of health information technology efforts. ONC is overseeing the achievement of meaningful use objectives, which are reported back to CMS to authorize financial reimbursement. Meaningful use is built on the five pillars of health outcomes (CMS, 2016):

- Improving care coordination
- Reducing health disparities among U.S. citizens, by improving the safety and quality of care
- Ensuring the security and privacy of protected medical information
- Engaging patients and their families in the patient's care
- Improving population and public health.

As of November 2016, approximately 605,000 eligible professionals and hospitals had signed up for the meaningful use incentive program (CMS, 2017).

Informatics and Service Delivery

Informatics has broad implications for service delivery. For example, addiction and overdoses of prescription opioids are an increasing problem in the United States. Reports of overdoses have increased more than threefold since the 1990s. In 2010, prescription medication overdose caused almost 17,000 deaths (Substance Abuse and Mental Health Services Administration, 2016). Efforts are being made to enhance tracking of prescriptions of opioids through electronic tracking at the state level. In addition, the Centers for Disease Control and Prevention (CDC) works with healthcare agencies to track prescriptions and emergency department visits for overdoses in an attempt to identify people who are or have been abusers (CDC, 2016). The ability to link computerized written orders with patient EHRs on regional and national levels can help identify and monitor individuals who are at risk, and make it easier to identify people who engage in "doctor shopping" to obtain narcotics for abuse or illegal sale. Tracking mechanisms can also help identify healthcare providers who write bogus opioid prescriptions and receive a financial kickback from sellers.

One of the often-cited benefits of EHRs is improved quality of care delivered to patients. As part of the meaningful use requirements, clinical quality measures must be reported (CMS, 2013a). An example of a large quality improvement project that can be facilitated with informatics is the Surgical Care Improvement Project (SCIP). The target population is all patients who are undergoing surgery, and the goal is to reduce surgical complications and improve surgical care. Hospitals started collecting data on certain quality indicators in July 2006. This is a collaborative project between The Joint Commission and CMS, and reimbursement for surgical procedures and hospital stays is tied to meeting SCIP measures (The Joint Commission, 2012). Informatics and the ability to retrieve information from patients' EHRs can help with such large-scale projects and also help facilities identify their own quality projects and areas for process improvement.

Concepts Related to Informatics

The use of informatics has created many new challenges for nurses. Patients have increasing access to a variety of health-related information, such as recommendations for diet and monitoring weight. Nurses must be attentive to ensure that their patients are getting good-quality information and using it appropriately. It is also important to recognize that some patients will be unable or unwilling to use electronic means to access health information. Nurses are in a good position to help patients find the most appropriate means of getting and using healthcare information.

Protecting health information is also important, and vigilance is necessary to protect patient information and to ensure that protected information is not released inadvertently. The rise of social media has created ethical challenges, especially when nurses and patients know each other socially from events or activities outside the workplace. Despite the great possibilities for improving patient care through quality improvement efforts and tracking patient use of medications, nurses must take care to use informatics within established guidelines consistent with the scope of nursing practice and professional, ethical, and legal requirements. Some, but not all, of the concepts integral to informatics are outlined in the Concepts Related to Informatics feature. They are presented in alphabetical order.

Healthcare Information Systems

The increasing use of technology by healthcare facilities requires that nurses have a basic knowledge of the types of information systems used, the purposes and abilities of these systems to support patient care, and the nurse's responsibilities related to using these systems.

In the days of paper charts, only one individual at a time could access a patient's chart and add information to it. A **clinical information system** allows multiple disciplines to simultaneously access the patient's chart and record data that can be viewed and analyzed by a number of healthcare providers in real time, providing the most accurate and current information about the patient so that the best decisions about the care of that patient can be made.

A clinical information system must give the nurse the ability to access patient information and provide data necessary to execute the nursing process of assessing, diagnosing, planning, implementing, and evaluating the care of the patient. When the system is used at the point of care, the nurse can immediately record patient information based on assessment of the patient's current condition. The nurse should also have access to diagnostic data (e.g., laboratory values), diagnoses, assessments, plans, and evaluations of the patient from the viewpoint of other healthcare professionals (e.g., physicians, physical therapists). Pharmacy information, such as medication, route, dose, and time, should be available in the patient's chart in real time. The chart should also include safety features, such as warnings for drug interactions or incorrect dosages. Most clinical information systems also contain clinical decision support, which is discussed later in this module. The system should also allow the nurse to print discharge instructions to review with the patient (Duke University, 2012; Locatelli et al., 2012).

Computerized Medical Records

On the surface, a computerized medical record may appear to be nothing more than a digital form of a patient's paper chart. Many systems start out that way. However, rapid technologic advances have transformed these static charts into dynamic systems.

Purpose

The purpose of a computerized medical record is to unify a patient's entire health history into one single source of information about the patient's health, including the patient's medical and surgical histories, diagnostic tests and treatments, medications, and therapies. It is meant to be multidisciplinary and multispecialty in nature. It is meant not to simply record the past but to aid clinicians in the patient's future healthcare, improve quality of care, lower costs of care, and facilitate research. It is meant to be portable, so that if a patient lives in New York but requires emergency care in Los Angeles, all of the patient's medical information is available to help the healthcare providers in Los Angeles make the best possible decisions about the care of the patient (Open Clinical, 2016). A survey of physicians found that 78% of physicians using EHRs reported that their use enhanced patient care overall; 81% indicated it helped them access a patient's chart remotely; and 65% stated it alerted them of a potential drug error (King et al., 2014).

To deliver the best quality of care, promote safety, and maintain efficiency, computerized health records should contain the following functionality (Open Clinical, 2016):

- **Patient support.** Patients should be able to access their health records. Patients can take a more active role in their care if they have the ability to track appointments and health maintenance, monitor their weight and laboratory results, and access educational materials related to their health condition.
- **Health information and data.** Important data, such as chronic and acute medical and psychiatric diagnoses, medications, allergies, and diagnostic tests, can help clinicians make rapid decisions if necessary.
- **Administrative processes.** The ability to manage schedules, insurance information, and inventory can help healthcare facilities focus on patient-centered care.
- **Results management.** Access to past and current diagnostic tests can help clinicians recognize changes in a patient's state of health faster.
- **Reporting.** Healthcare facilities can comply more easily with regulatory requests and help report disease surveillance and patient safety matters such as medical device recalls.
- **Secure electronic communication and connectivity.** Secure and accurate communication between medical providers at different facilities that are caring for the same patient help with continuity of care and timely diagnoses.
- **Order management.** Computerized physician order entry (CPOE) helps with accuracy and decreases times from order to treatment. CPOE should be available for pharmacy, laboratory, radiologic tests, and ancillary services such as physical and occupational therapy.

Concepts Related to Informatics

CONCEPT	RELATIONSHIP TO INFORMATICS	NURSING IMPLICATIONS
Addiction	<p>EHRs give healthcare providers, including nurses, access to the patient's entire health history, not just information from this particular encounter at this particular facility.</p> <p>Linking of EHR information may help identify individuals who are at risk for opioid addiction and who are engaged in obtaining these drugs illegally.</p>	<ul style="list-style-type: none"> ■ Assess appropriate use of addictive medications; many patients have legitimate need for prescription opioids. ■ Be alert for duplicate opioid prescriptions within a patient's record, especially from multiple providers.
Ethics	<p>With social media, lines between patients and providers can be blurred.</p>	<ul style="list-style-type: none"> ■ Nurses must be aware that many employers monitor their employees' activity on social media; the legality of disciplinary action for a post showing the employee intoxicated and/or engaging in illegal activity or requiring employees to give employers their passwords is still being established. ■ Nurses must weigh the implications of "friending" patients that they care for (especially in areas with long-term interaction). ■ <i>Anticipate</i> how to handle patients who attempt to cross boundaries by using social media.
Legal Issues	<p>It is necessary to keep protected health information confidential and to ensure that the information entered in a patient's health record is accurate.</p>	<ul style="list-style-type: none"> ■ Nurses must be aware of HIPAA and HITECH rules. Among the most critical activities: <ul style="list-style-type: none"> — Keep passwords private. — Do not leave screens containing protected health information unattended. — Access charts only of patients to whom you are assigned. — Always verify that you are charting on the correct patient's chart and that the information is recorded accurately.
Nutrition	<p>Smartphone applications allow patients to determine and track the nutritional value of foods they eat.</p>	<ul style="list-style-type: none"> ■ Use of these applications may increase ease of tracking nutritional intake for the purposes of dietary recall and weight monitoring. ■ Anticipate that some patients may not have smartphones or may have minimal data plans that limit their ability to use this technology. Work with patients to establish other, convenient means to track dietary intake.
Quality Improvement	<p>With many EHRs, quality metrics can be easily tracked for improvement within a department or hospital system. Tracking information to use for quality improvement initiatives requires users to understand how to use technology correctly. Nurses must be at the table as new systems are evaluated and put in place, and they must advocate to ensure that they will receive adequate training to implement the system safely and accurately.</p>	<ul style="list-style-type: none"> ■ Assess your own comfort and ability level related to use of electronic/computer equipment. Attend and pay attention in training sessions; seek follow-up help as necessary. ■ Be alert for the possibility for error; enter information accurately the first time.
Safety	<p>EHRs can provide tools to improve patient safety such as reminders.</p> <p>Clinical Decision Support Systems are also used to ensure that appropriate protocols are used when patients meet certain criteria.</p>	<ul style="list-style-type: none"> ■ Nurses benefit from electronic reminders to assist them when they are busy to ensure that key assessments such as neurologic assessments in stroke patients are done in a timely manner. ■ Flags in the system alert nurses to complete screening tools such as falls risk or pressure ulcer screening. Healthcare providers can access evidence-based practice care bundles for patients who meet criteria for sepsis and other diagnoses.

- **Decision support.** The care of the patient can be enhanced through the use of a clinical decision support system. These systems can display best practice standards, notifications for preventive screenings, and alerts for drug interactions.

Terminology

A nurse will hear many different terms to describe a computerized medical record, and the list will probably continue to change. The two most commonly used terms are electronic medical records and EHRs.

Electronic medical records (EMRs) are similar to an electronic chart used in a clinician's office. Their focus is on diagnosis and treatment. They can help track information over time (e.g., weight, blood pressure, cholesterol readings) and identify when patients are due for routine preventive health maintenance such as vaccines and mammograms. A disadvantage of these systems is that most of them are designed to stay within a clinical setting and are not meant to travel beyond it. A patient who needs to see a specialist may need a paper printout of the EMR to take to the special appointment.

Electronic health records (EHRs) give a broader view of the patient's health. They are designed so that multiple clinicians from multiple disciplines (e.g., family practice, nursing, pharmacy, specialists) can all have simultaneous access to the patient's health information. This access provides patients with more comprehensive management of their health and is designed to improve the quality of care they receive. EHRs enhance communication with other clinicians, they provide easy access to patient information, they can provide automated formulary checks by health plans to avoid problems with prescriptions, and they can link to public health systems such as registries and communicable disease data banks (HealthIT.gov, n.d.a). One significant advantage is e-prescribing, in which healthcare providers can communicate directly with the pharmacy to order prescriptions. This can reduce errors, lower costs, and improve care (HealthIT.gov, n.d.b).

This text uses *EHR* when discussing documentation, as it is the broader, more encompassing term.

Components

Real-time documentation of patient data can help all clinicians care for the patient. The nurse should be given the tools to record assessments, nursing diagnoses, plans, interventions, and evaluations. The work that nurses have done in caring for the patient has traditionally been invisible to other disciplines, so the ability to carry the nursing process over into electronic records will help promote the work that nurses do in caring for the patient. *Uniform language* is the consistent use of the same terminology among providers, facilities, institutions, and organizations when describing all patient data, including that pertaining to assessment and treatment. Uniform language (discussed further in the exemplar on Clinical Decision Support Systems in this module) is vital for communicating to other nurses and health professionals the value that nurses provide in the care of the patient.

NANDA International (NANDA-I) has been involved in developing uniform language for nursing since the 1970s.

NANDA-I diagnoses are available in many electronic health systems (Meum, 2013). The Nursing Interventions Classifications (NIC) include both physiologic and psychologic interventions that nurses perform with patients and their families. Nurses use both NANDA-I and NIC to formulate care plans for the patient in the EHR (Meum, 2013). The Nursing Outcomes Classification (NOC) is designed to assess the outcomes of patients based on the nursing interventions performed. Both NIC and NOC have been approved for use in **Health Level 7 (HL7)** terminology, which provides a framework and composes standards "for the exchange, integration, sharing, and retrieval of electronic health information that supports clinical practice and the management, delivery and evaluation of health services" (Health Level Seven International, 2013).

Health Insurance Portability and Accountability Act of 1996

A major concern for both patients and healthcare providers is the protection of private health information. Private health information includes any details that could identify a particular patient, such as name, phone number, hospital medical record number, diagnosis, or Social Security number. The U.S. Department of Health and Human Services issued a set of privacy rules called the Health Insurance Portability and Accountability Act of 1996, commonly referred to as HIPAA. It set rules to limit who may have access to a patient's health information, whether that information is in written, oral, or electronic form. It also gives patients the right to view their own health records, make corrections to their records, and receive notification of how their information may be used or shared (e.g., for research or marketing purposes; U.S. Department of Health and Human Services, n.d.). The Health Insurance Technology for Economic and Clinical Health Act (HITECH) added more strength to the existing HIPAA protection of patients' medical information (Solove, 2013).

Nurses should use many of the same rules for protecting patient privacy that were practiced before the advent of electronic records. Information about a patient should not be discussed in public areas, such as hospital cafeterias or elevators. Any paper documents that may contain protected health information should be placed in designated shred bins. Newer considerations for nurses include not sharing passwords, not leaving a computer screen with protected health information unattended, and not posting any patient information on public social networks such as Facebook, Instagram, or Twitter (see **Box 48-1** and **Figure 48-1**). Commonsense habits related to confidentiality must be practiced. In the days of paper charts, it may have been possible to obtain unauthorized access to a neighbor's or celebrity's chart without being detected. Now it is very easy to ascertain electronically each time a patient's chart is accessed and by whom. A nurse who improperly accesses a patient's chart could face loss of employment and possible fine, loss of licensure, and/or legal action.

Despite the move to EHRs, medical fraud still occurs. The cost to Medicare and Medicaid is roughly \$98 billion and the cost to the entire healthcare systems is around \$272 billion per year. Fraud occurs through the charging of "false visits,"

Box 48–1

Social Media and the Workplace

In 2016, almost 2 billion people worldwide used some form of social media; Facebook had the largest share of users (Statista, 2016). In a study conducted in 2011, 87% of physicians surveyed reported personal use of social media, and 67% reported professional use (Federation of State Medical Boards, 2012). Social networking can pose several ethical dilemmas for healthcare providers. Some employers have demanded access to their employees' social media accounts or have monitored employees' activities. As of 2016, over a dozen states had made it illegal for employers to require employees to provide passwords or access to an employee's social media accounts, and several other states have legislation pending (Guerin, 2016).

The other challenge in the workplace is navigating the use of social media by providers. The National Council of State Boards of Nursing (NCSBN) has developed a set of media guidelines for nurses (NCSBN, 2014). They caution that inappropriate posts by nurses to social media can result in licensure and legal repercussions. Sharing any information at all about patients with your friends on social media is inappropriate and violates HIPAA and the Nursing Code of Ethics.

» **Stay Current:** Visit the website of the National Council of State Boards of Nursing to view a video of guidelines for use of social media.

Many institutions have developed policies to guide staff and providers on whether or not they can “friend” patients on Facebook. Many providers do not “friend” patients on personal Facebook, as this generally is a less professional site and reserved for their friends and family (NPR, 2015). However, social media is a powerful tool and a great way to communicate with the millennial generation, so many institutions and provider practices set up institutional Facebook, Twitter, Instagram, Pinterest, and Google Plus sites where they can distribute general information to patients. They can provide educational videos on subjects such as diabetes, remind patients to get flu shots, or disseminate other important information (U.S. News, 2014).

Social media is not the only electronic tool presenting challenges for providers. Some hospitals and healthcare offices use emails and text messages to notify physicians about a patient's status (Baum, 2015). If this information is not encrypted and includes a patient's name or other identifying factors, it may be classified as a HIPAA violation. To mitigate this risk, employers now require the use of mobile security services that protect devices at both the device and application levels so that if a device is lost or stolen, access to the sensitive data can be disabled. Text messages can also be set to delete after having been read (“Text messaging apps for hospitals,” n.d.).

overbilling for services, prescription fraud, and unnecessary ambulance transports. To combat this, CMS is enlisting patients to scrutinize their bills for charges that don't seem accurate. Nurses should educate patients about these scams and how to protect themselves (The Economist, 2014).

Quality Assurance

On the surface, the implementation of EHRs would seem likely to automatically improve the quality of patient care. It has the potential to do that, but an EHR is just a tool, and outcomes of care depend, in part, on how this tool is used.

Source: Wavebreakmedia/iStock/Getty Images.

Figure 48–1 » Do not post any information at all on any social media about any patient in your facility.

Accuracy

Recording accurate patient health information is vital, whether the nurse is using a paper or an electronic system. First encounters with an electronic charting system involve a learning curve that increases the chance of errors in recording data that will be left in a patient's chart. For example, someone who is new to the system may not know how to remove a blood pressure reading that was 225/124 because the arterial line transducer was on the floor or how to mark that reading as faulty data. In many charting systems, more than one chart may be open at the same time, so entering information on the wrong chart may be easy. An accidental click of a mouse on the wrong medication can cause the provider who is not paying attention to order or give the wrong medication. **Device integration**, which automatically enters patient vital signs into the EHR, is possible in some systems. This has increased in use and is found not only in intensive care units but also in telemetry, obstetrics, and even general care units. Device integration allows real-time accurate data to be recorded in the patient's chart directly from the device (e.g., a blood pressure monitor or cardiac monitor). It allows the nurse to more quickly analyze and interpret that data and make adjustments to the plan of care based on the most current information. In one study of ICU patients, 95% of vital signs were recorded at least once per hour, and clinicians validated most of the data within 15 minutes of its being recorded (Pizzi, 2013). As EHRs evolve, more departments are likely to use device integration.

Some EHR systems use templates and cut-and-paste functions designed to promote efficiency. For example, a pediatric clinic seeing 10 otherwise healthy children who have ear infections can use a template or cut/copy function

to forward the information that is within normal limits and just focus on the infection, saving precious time that would otherwise be spent manually clicking boxes for negative or normal findings. However, overuse of these functions can result in inaccurate data being recorded in a patient's chart, risking future decisions about medical care based on faulty information. For example, if there has been a significant change in the patient's condition and a practitioner uses a "copy forward" function to duplicate the previous day's progress notes, then care of the patient can be seriously compromised. One study found that up to 20% of material in a patient's chart was the result of copy-and-paste (Stokes, 2013). A patient's medical record is only as valuable as the information that is entered in it, and nurses have a duty to ensure that they enter only timely and accurate information. Risk management, insurance companies, and regulatory bodies as well as other clinicians will be looking at the data in the patient's record, so it is imperative that nurses take the time to learn proper documentation within the electronic system that their employer adopts.

Critical Thinking

The fact that the EHR is merely a tool cannot be overemphasized. As with paper charting, the patient and not the record should have first priority in the nurse's attention. Although it may be difficult when electronic records are used, nurses must learn to focus their attention on the patient and not the computer. Employers should give nurses adequate training on the use of their electronic system and provide mentors to help decrease the stress of adding one more activity to the nurses' already busy workload (Goldberg et al., 2012).

Clinical decision support systems are a type of artificial intelligence that analyzes data and provides information about evidenced-based practices. These systems can help improve patient safety and quality of care. However, they cannot take the place of sound nursing judgment. The use of clinical decision support systems in nursing practice is described further in the exemplar on Clinical Decision Support Systems in this module.

Uniform Language

For greater efficiency, nurses should use uniform language in their documentation. Uniform nursing diagnoses, along with uniform descriptors of nursing interventions and outcomes, can help clarify care of the patient not only to other nurses, but to other disciplines as well. Some documentation within an electronic record may have only standardized descriptors available for the end user. The use of uniform language also aids nursing research (National Association of School Nurses, 2012).

Clinical Example A

Mary Wilson is a 19-year-old with a history of grand mal seizures. She takes two antiepileptic medications: phenytoin and topiramate. Her seizures are fairly well controlled, and she has an average of three seizures per year. Ms. Wilson is getting ready to go out of state to college and visits her primary care provider for a physical before she leaves. The office has just installed a new EHR system. Because of an early regional outbreak of influenza, the office is overbooked on appointments. The practitioner that Ms. Wilson usually sees is on vacation. The other practitioner rushes through Ms. Wilson's appointment and

does not take a thorough history or discuss medications that she is taking. Ms. Wilson presents as a healthy 19-year-old, so the practitioner uses the "copy and paste healthy adult" format for her chart.

Ms. Wilson goes out of state to school. After class one day, she decides to go for a run to relieve the stress of her classes. While she is on her run, she experiences a grand mal seizure. A motorist finds her unconscious in a postictal state and calls for emergency services. Ms. Wilson is transported to the hospital, which happens to be on the same EHR system as her primary care provider. She is still not conscious when she is examined, but she has identification with her name and birthdate on it. The emergency department staff looks at Ms. Wilson's EHR, but there is no mention of her seizure disorder. She is sent for emergency CT scans and an MRI of her brain.

Critical Thinking Questions

1. What mistakes did the provider at Ms. Wilson's primary care office make with her record?
2. How did the omission of information affect the care that Ms. Wilson received at the hospital?
3. What complications regarding health insurance might arise if she is at an out-of-state school?

Telehealth

Telehealth uses telecommunications technologies (e.g., videoconferencing, streaming media, store and forward imaging, and land-based and wireless communications) to allow patients access to care that they might not otherwise be able to obtain. The terms *telehealth* and *telemedicine* are often used interchangeably, but according to the Health Resources Administration, *telehealth* is much broader and can encompass health-related education, public health, and health administration (HealthIT.gov, n.d.b). Telehealth is not meant to replace all provider face-to-face visits, but it can be used to help manage patients with chronic physical and mental disorders, particularly those who live in rural areas where access to specialists is limited or requires travel. In many states, reimbursement for telehealth visits is the same as that for in-person visits. This makes telehealth an attractive and cost-effective option for both patients and providers (Pena & Sanders, 2016). Patients still must see a provider in person, and there are limits on the number of telehealth visits that insurance will pay for. However, not all states have agreed to pay for telehealth services in the same way; for example, Texas and Arizona are more restrictive in the reimbursement and use of telehealth services (Lagase, 2016).

Research on the effectiveness of telehealth has found evidence to support its use in patients with chronic conditions and with those receiving psychotherapy as part of behavioral health. In particular, improvement in outcomes such as mortality, quality of life, and reductions in admissions were seen in patients who were followed with chronic diseases (Landi, 2016).

Benefits of telehealth include:

- **Access to healthcare is increased.** Patients in rural areas can reduce the need to travel, and they receive access to specialists that may not be available in their community.
- **Health outcomes are improved.** Increased access to care can reduce complications and increase diagnostic and treatment options from specialists.
- **Healthcare costs can be reduced.** The expenses involved in frequent long-distance travel are reduced or eliminated,

and home monitoring of chronic conditions can help reduce hospital admissions.

- **Telehealth may help with shortages of healthcare providers.** Many new graduates are not willing to move to rural communities. Telehealth can give patients access to primary care providers and specialists from other areas.

A 2016 survey by the American Telemedicine Association (ATA) found that approximately 15 million Americans had received some kind of medical care remotely in the past year. In addition, the ATA surveyed 280 healthcare executives and found that 72% of hospitals and 52% of physician groups use some kind of telemedicine program (Beck, 2016).

» **Stay Current:** Visit the website of the American Telehealth Organization for updates on current policies, including the latest on CMS reimbursement and support for telehealth (<http://www.americantelemed.org/home>).

Barriers to Patient Participation

Some patients may be reluctant to use telehealth services because their insurance company may not cover the cost (California HealthCare Foundation, 2013a, b). Older adults who lack understanding of or experience with technology may be reluctant to use telehealth services. The lack of availability of broadband internet service throughout the country also limits participation. In addition, many patients are not aware that these services exist or that their healthcare provider is willing to participate in this type of interaction. On the provider side, reimbursement challenges still exist and vary from state to state. Obtaining a license to practice across state lines varies by state. Some offer a special telehealth license, and some allow providers to practice in bordering states (Center for Connected Health Policy, 2016).

Clinical Example B

Jack Anderson is an 85-year-old retired machinist. He has an eighth-grade education and lives on a fixed income in a rural community 100 miles from a major city. He has congestive heart failure (CHF) and takes a loop diuretic (furosemide) and digoxin for his condition, both of which he gets through a mail-order pharmacy. Mr. Anderson has Medicare but tries to limit his doctor visits because he doesn't like to drive to the city, and the cost of gas puts a strain on his monthly budget. His community has high-speed internet, but Mr. Anderson has not installed it because "he moved to the country to get away from everyone."

Critical Thinking Questions

1. Discuss several factors that would make Mr. Anderson an ideal candidate for telehealth.
2. When Mr. Anderson comes in for an appointment, what could the nurse say to encourage Mr. Anderson to participate in telehealth to manage his CHF?
3. If Mr. Anderson agrees to participate in telehealth, what should the practitioner assess in each of the telehealth sessions with Mr. Anderson?

Geographic Information Systems

A **geographic information system (GIS)** uses location to capture, manage, and analyze data. This technology has been used both inside and outside of healthcare. It relies on satellite imaging and the global positioning system (GPS) to

capture geographic data. Those data are then managed and stored on a database. Healthcare policy makers, researchers, and public health professionals use GIS to understand a health problem, decide the best response to that problem, and plan ways to avoid the same or a similar problem or keep it from occurring again (HIT, 2015). GIS is being used to:

- **Identify health trends.** This combines individuals' health data from electronic records, data from wearables, and data from their environment to determine if there are clusters of cancer in an area or obesity related to certain areas or climates
- **Track the spread of infectious diseases.** Data is used to map where diseases are mostly likely to spread next and gain an understanding of vaccination rates
- **Use personal technology.** Data from wearable technologies has the ability to determine trends in heart rate and sleeping patterns of individuals and to determine if that varies in different geographic areas
- **Incorporate social media.** Through the use of social media, researchers are able to query posts or tweets for keywords such as *flu* or *influenza* to create a visual map of where the flu outbreaks are geographically located.

Public health nurses and administrators can use GIS to track where chronic disease programs should be placed, to monitor the effectiveness of these programs, to plan new treatment facilities, and to track acute health problems, among many other uses. GIS gives healthcare providers the tools to show where services are provided and where health services are needed. Gaps between available programs and the needs of the community can be identified easily (Miliard, 2014).

Patient Education and E-Health

Besides changing the ways in which healthcare providers handle and use information, informatics is changing the way patients view their health. Some studies have indicated that when patients have access to their EHRs, they feel more knowledgeable about their health and disease processes, are more engaged during visits with their primary care provider, and feel more empowered to participate in disease management and wellness activities (Woods et al., 2013). Smartphone technology offers many add-on utilities and applications. Individuals can read and monitor their blood pressure or track their blood glucose levels using smartphones. Many fitness training applications allow users to share their successes on social media sites. Other applications are available for tracking calories in certain food items, recording caloric intake for the day, and tracking weight loss.

Wearable technologies such as fitness bands (Fitbit, Garmin, Apple Watch) have become popular. Many people use them to track steps, count calories, track quality of sleep, and set fitness goals. As these devices become more sophisticated and more personalized, they will be able learn each individual's habits and give more personal advice (Ghose, 2015). As records and applications continue to evolve, this information may eventually become directly transferrable into a patient's EHR. However, the need to ensure that these devices and applications are without risk to patients and do not compromise their privacy presents a complicated challenge

to government regulators (Hamel et al., 2014). Nurses need to understand a patient's level of e-health literacy as more people turn to online sources of health information and patient portals are increasingly being used for patient information (Park et al., 2016).

Online Consumer Medical Information

E-health uses electronic information that can be retrieved online or through a mobile device to improve a person's health or healthcare (U.S. Department of Health and Human Services, 2013). A survey found that 71% searched for information online. Of those searches, 60% searched for information about prescription drugs and 35% asked their physician to make a change by either adding a drug or discontinuing a drug. Another 57% searched for a diagnosis based on their symptoms and then proposed a diagnosis to their healthcare provider. The survey also found that nearly half of Americans go online to find reviews of healthcare providers. Despite the increased use of the internet to search for information, they still track key health factors on paper or in their heads as opposed to mobile devices (Wire, 2015). Another study found that when people have difficulty accessing health services, they turn to the internet and online resources to find health information more often than do those who have good access to healthcare.

Box 48-2 » provides some information on evaluating health-related websites that is useful for both patients and nurses who want to stay current.

Box 48-2

Evaluating Web-based Health Information

When looking online for medical information, ask yourself the following questions:

- **Where does the information come from?** Reliable websites clearly indicate the source of the information. They often provide additional sources of information.
- **Who hosts the site?** Websites that end in .gov are government-sponsored; .org indicates a noncommercial sponsor; and .edu identifies an academic or university sponsor. These are usually reliable sources of information. Websites that end in .com indicate commercial sponsorship and may or may not provide accurate information.
- **What type of information is presented?** Is the information authored by a health professional or scientist? Is the information evidenced-based? Does it contain research information?
- **Is the information current?** Review dates should be clearly posted. The most current information should be used, as practices in some areas change rapidly.
- **Is the website trying to sell a product?** Websites that are promoting a product or supplement probably do not contain accurate information and should be avoided.
- **Is your privacy being protected?** Read the website's privacy policy. Do not provide personal information unless you are comfortable with how the website will handle that information.

Online Patient Medical Information

Many health facilities are using the internet to give patients access to and control over their own health records. Some of these sites are called *patient portals*. Online registration is required, and a user identification and password are needed for each visit. Through many of these portals, patients can schedule routine appointments and request prescription refills from their primary care office (**Figure 48-2** »). Patients also can communicate electronically with their health provider, although some portals are not yet encrypted to allow secure transmission of protected health information. Hospitals are using the internet to schedule some radiology procedures such as mammograms online. Some EHRs allow patients to access parts of their health records. Information such as laboratory and pathology reports, medication records, and due dates for routine screenings and immunizations may be available. The use of these services leads to higher patient satisfaction and retention within the health system (Turley et al., 2012). However, with increased access comes a concern over security of the data. A 2015 survey conducted by the Pew Research Center found that people are sensitive about their personal health information and worry about the security of the data that might be accessible online through the patient portals (Pew Research Center, 2015).

Online Administrative Tools

Patient portals can also perform administrative functions. Patients are able to view and verify their demographic and insurance information. Many providers are placing their new patient paperwork online for patients to complete before their first appointment. Some systems send automated text or voice message reminders for upcoming appointments. Other systems may send automated messages to a group of patients, such as reminders for influenza vaccinations. The patient often has the ability to view any outstanding balances and make payments online.

Many hospitals are using the internet to have patients complete questionnaires about their treatment preferences. Patients can request the gender of the physician, the distance they are willing to travel, and a language accommodated other than English.

A major health insurance program is now allowing patients to price-shop the costs of surgical procedures or diagnostic tests such as MRIs. It also allows patients to see out-of-pocket costs for each health service and keeps track of the patient's contributions to deductibles for the year (Weisman, 2013).

Health insurance companies give providers online access to information about the patient's insurance coverage, including information on providers and hospitals in the insurance company's network. Providers often can see the dates of coverage and co-pays and deductibles paid to date, and in some cases, they can obtain instant online authorization of procedures such as MRIs.

Some websites allow patients to compare health professionals based on specialty, languages spoken, and clinical training. Hospitals and nursing homes can be compared based on quality measures and demographics (e.g., location, size). Websites vary: Some use only patients' ratings, and others use less subjective data.

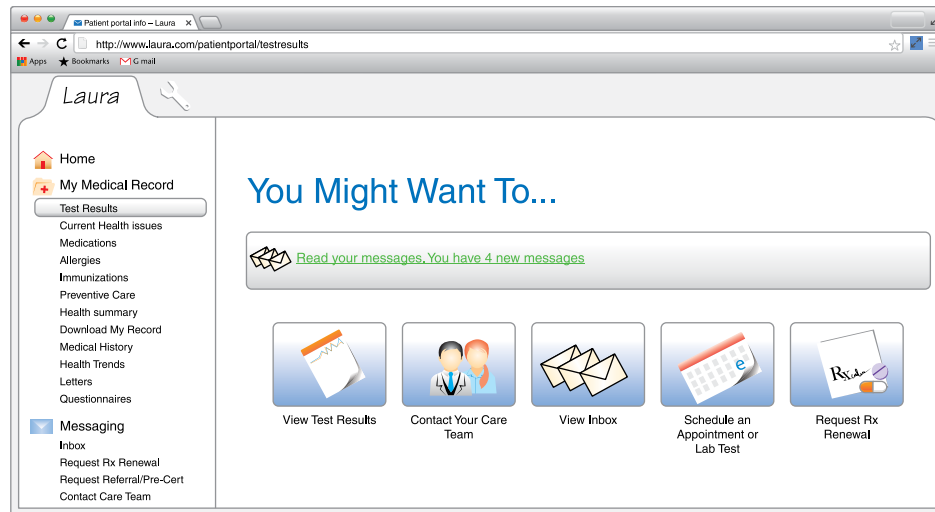

Figure 48-2 » Patients can use their patient portal to send and receive messages, view test results, schedule an appointment, and order prescription refills.

Ergonomic Considerations

More and more individuals—patients and professionals—are using technology, often for hours a day. Use of technology can impact both work flow and body mechanics. The addition of computers in healthcare may seem innocent enough, but without proper planning and implementation, it can lead to serious injuries to the user. The risk of injury increases with professions that require pushing, pulling, frequent or heavy lifting, prolonged awkward positions, or repetitive, forceful, or prolonged exertion of the hands (U.S. Department of Labor, n.d.a).

Ergonomics is “the science of fitting workplace conditions and job demands to the capabilities of the working population”

(U.S. Department of Labor, n.d.a). Ergonomics examines the type of work being done, the tools being used, and the body mechanics of both the work and the tools, and then suggests the best way to do that work with those tools to limit overuse and harm (U.S. National Library of Medicine, 2016).

For working on a computer, the goal of ergonomics is to set up a workstation that allows a neutral body position (**Figure 48-3** »). The head, neck, and torso should be in alignment. Shoulders and upper arms should be perpendicular to the floor and relaxed. The upper arms and elbows should be close to the body. Forearms, wrists, and hands should be straight and in line. When the worker is sitting, the thighs should be parallel to the floor and the feet should rest flat on

Figure 48-3 » Maintaining neutral position while working at a computer will help prevent the development of repetitive strain injuries.

the floor or be supported by a footrest (U.S. Department of Labor, n.d.a).

»Stay Current: A checklist that looks at each component of the computer system (keyboard, monitor, chair, and work surfaces) is available online at www.osha.gov/SLTC/etools/computerworkstations/checklist.html.

Workstations on wheels (WOWs) add requiring the user to pull or push them to different locations for use. The position of the monitor, keyboard, or mouse on the WOW can also lead to bad posture and injury. These carts should be as lightweight and maneuverable as possible. Ideally, the user should be able to tilt the screen at different angles, and workstation platforms should be adjustable to varying heights. See **Box 48-3** » for ways to incorporate good ergonomics in computer use.

Improper workstation setup or improper body mechanics can lead to injury. Common complaints after prolonged computer use include fatigue or pain in the neck, shoulders, back, arms, wrists, and hands. Some of these symptoms can be alleviated by proper ergonomics or breaks from the computer when possible. Sometimes simple aches and pains can lead to more serious injuries that cause disability. The two most common injuries are repetitive strain injury (RSI) and computer vision syndrome (Princeton University, University Health Services, 2017).

Repetitive strain injury, or repetitive motion disorder, occurs when the limbs are subjected to repetitive use, awkward positions, or forced positions. These injuries can affect nerves, tendons, and muscles. Tendinitis is a common occurrence, but carpal tunnel syndrome is more serious and can lead to permanent disability if not treated. Symptoms of tendinitis include pain in the wrist, elbow, shoulder, or neck; numbness or tingling in the fingers; difficulty grasping objects; and a decrease in the size of the affected hand. Treatment should not be delayed and can include changes in posture, stretching, muscle strengthening, and rest. Rest is a key component; treatment and healing require time. Carpal tunnel syndrome is a more serious repetitive strain injury caused by repeated bending or use of the fingers or wrists that results in median nerve compression. Pain, numbness, and tingling in the palm of the hand and in the thumb and index fingers or the middle fingers are common symptoms. Surgery may be required if the injury is severe enough or does not respond to conservative treatment. If left untreated,

Box 48-3

Good Ergonomics for Computer Use

- Maintain good posture whether sitting or standing, aligning your ears, shoulders, and hips.
- Avoid overreaching. Keep the keyboard and mouse within easy reach.
- Keep your wrists in a straight position and your elbows at a slightly open angle.
- Position the monitor so that you can see the screen without tilting your neck up or down or turning your head.
- Use light force when typing on the keyboard.
- Customize font sizes and screen resolution to maximize comfort.
- Take frequent breaks. Eye breaks are important as well as stretching and moving around at regular intervals.
- Ensure proper lighting and reduce glare from the screen.

If you experience numbness, weakness, or pain, seek medical attention.

Sources: Based on University of California at Los Angeles. (2012). *Tips for computer users*. Retrieved April 20, 2013, from <http://ergonomics.ucla.edu/homepage/office-ergonomics/tips-for-computer-users.html>; Princeton University, University Health Services. (2017). *Ergonomics and computer use*. Retrieved from <http://www.princeton.edu/uhs/healthy-living/hot-topics/ergonomics>; University of Michigan Health Services. (2017). *Computer ergonomics: how to protect yourself from strain and pain*. Retrieved from <https://www.uhs.umich.edu/computerergonomics>.

carpal tunnel syndrome can lead to muscle wasting, decreased sensation, and permanent disability (Princeton University, University Health Services, 2017).

Computer vision syndrome, or eyestrain, is the most common sequela of computer use. Using the computer for more than 3 hours a day puts one at risk, so many individuals are affected. Symptoms include eye fatigue, headaches, blurred vision, dry eyes, and changes in color perception. If left untreated, computer vision syndrome can lead to a decrease in work efficiency, general fatigue, and increased myopia. It can be caused by monitor glare, monitor position (too close or incorrect angle), or quick eye movements while typing and looking at a source document. Correct monitor position, anti-glare screen covers, correct lighting, and proper document placement can all help reduce the effects of computer vision syndrome. It is also important to take breaks and to blink (Princeton University, University Health Services, 2017).

REVIEW The Concept of Informatics

RELATE Link the Concepts

Linking the concept of informatics with the concept of legal issues:

1. Name three ways in which a nurse can keep protected health information secure.
2. What are some ramifications of looking up information in a local celebrity's chart if you are not taking care of that individual?

Linking the concept of informatics with the concept of addiction:

3. You are a nurse at a busy inner city emergency department. It is 3 a.m. on a Saturday when a patient comes in asking for a

narcotic prescription. She reports that she usually gets her prescription from her primary care provider for ankle pain from an old injury, but she forgot to call during the week. Describe how an EHR can assist you in caring for this patient.

4. What type of questionnaire tools could be built into an EHR to assist with screening patients for chemical dependency?

REFLECT Apply Your Knowledge

Susan Johnson is a 45-year-old RN who works in a busy medical-surgical unit. Her hospital just installed an EHR system, and because of the layout of the unit, it was decided that the nurses would chart using workstations on wheels. Susan is excited about the new computerized system and has adapted to it quickly. She usually works three 12-hour shifts a week, but a few nurses are out on maternity leave, so she has been picking up extra hours. She has been noticing

some tension and pain in her neck and shoulders, especially after her shifts.

1. What are some factors that may be contributing to the tension and pain in Susan's neck and shoulders?
2. What are some things that Susan could try to alleviate these symptoms?
3. What are some advantages to using WOWs for patient documentation?

48.A Analyze clinical decision support systems as they relate to informatics.

- Describe the role of uniform languages in clinical decision support systems.
- Describe the use of computers in nursing research.
- Describe the use of computers in nursing administration.

Exemplar Key Terms

Clinical decision support systems, 2820
Dashboard, 2821

Overview

Clinical decision support systems (CDSSs) are an important addition to EHRs. A CDSS can be a general system that is used as developed by the vendor, or it can be customized by the organization. A CDSS uses a knowledge base and programmed rules, protocols, and evidence-based guidelines to match against patient data in the EHR and deliver alerts or recommendations to the provider. A CDSS can improve patient care by through the reduction of medication errors, increase adherence to best practice protocols, and decreased costs. However, a CDSS can be challenging: If it is not set up correctly, too difficult to navigate, or creates too many alerts leading to alert fatigue, users will become frustrated, and this can impact patient care. Users also may become dependent on the system and not use their own critical thinking and judgment (Castillo & Kelemen, 2013).

Nurses' Use of Clinical Decision Support Systems

EHRs and CDSSs are designed to provide nurses with alerts, reminders, and recommendations to guide best practice and support clinical decision making. Piscotty and Kalisch (2014) conducted a literature review that examined nurses' use of these systems. They found four factors that impact the use of CDSSs: patient factors, nurse factors, technology design factors, and organizational factors. Nurses tended to use the guidelines more often early in their careers or when caring for unfamiliar patients. They also used the guidelines to back up their decisions. Technology design factors that supported use were limiting the number of reminders, strategic location of the workstations, administrative support for issues, ability to adapt the technology, and good ergonomics.

Barriers to use were heavy workload, poor interface, lack of trust in the information, and lack of reminder flexibility. Organizational support was necessary for adoption of use (Piscotty & Kalisch, 2014).

Using Research

The use of EHRs that contain clinical decision support systems should help promote best practices through nursing research and make it easier to use current nursing research at the point of care (Topaz et al., 2012). Research in the area of adoption of CDSS is helpful in understanding the barriers to using those best practices. A study by Khong et al. (2015) found that some nurses were resistant to using a CDSS and instead relied on their own "gut" instinct for how best to manage wound care or continued to conduct wound care as they had in the past.

Computers in Nursing Research

With the introduction of the EHR, computers will be available to nurses in all practice settings. Research environments will be no different. Conducting nursing research should be easier with the use of uniform language and the ability to query EHRs. The steps of the nursing research process should remain the same. Technology can assist nurses in many ways to gain additional information: The nurse can use the EHR to research the patient's medical history to determine if the patient has been prescribed a particular drug and what responses the patient experienced following administration. The nurse can use the internet to conduct a literature search to determine if there is more information on use of that drug in certain populations or to get additional information related to potential side effects. For a detailed discussion of nursing research, including a list of

nursing research databases, see the module on Evidence-Based Practice.

Computers in Nursing Administration

Many EHRs give administrators tools to manage budgets, staffing, quality initiatives, and productivity information. The use of dashboards puts all of this information at the administrator's fingertips. A **dashboard** presents information about a healthcare facility's key performance indicators and displays the information in an easy-to-read format, often with charts or graphs. Some information can be displayed in real time. EHRs can create reports that track data over short-term periods (the past week) or long-term periods (the past year).

Human Resources

Human resource departments and payroll departments can benefit from computerization by tracking personnel within the healthcare system. Professional licenses and credentials expire and must be renewed. It would be a daunting task to keep track of this information manually for a large facility that employs thousands of healthcare professionals. A computerized system can monitor license expiration and when recredentialing of a provider is required. Mandatory hospital education, employee attendance, and performance reviews can all be tracked. When government regulatory agencies make their visits, all of this information is easier to obtain and review. Payroll systems are more accurate with a computerized system. Employees can have access to their available hours of vacation and sick time and may be able to view their paycheck online a few days before they are paid.

Medical Records Management

Much of medical records management revolves around finances. The process begins when a patient schedules an appointment or enters the system on an emergency basis. An informatics system can help schedule the appointment, verify insurance coverage and co-pay information, collect the patient's demographic information, and collect any outstanding payments or co-pays. If the patient is being admitted to the hospital, the system can help with obtaining insurance authorization and assigning a room and bed that have been marked clean and available by the system (and a roommate of the same gender if it is not a private room). The patients' condition can be coded for payment based on their ICD-10, CPT, or HCPCS code (HIMSS, 2016). ICD-10 codes replaced ICD-9 codes on October 1, 2015. The International Classification of Diseases (ICD) codes are used to report inpatient procedures and medical diagnosis (CMS, 2013b). Current procedural terminology (CPT) describes surgical, medical, and diagnostic services; hearing and vision services; occupational and physical therapy services; and transportation services (such as an ambulance; American Medical Association [AMA], 2013). The Healthcare Common Procedure Coding System (HCPCS) contains two levels. Level I is the CPT coding. Level II codes a wide array of services, such as durable medical equipment, outpatient chemotherapy drugs, medical supplies,

orthotics, and prosthetics (American Academy of Professional Coders [AAPC], 2016).

Facilities Management

Another system that most nurses are unfamiliar with is materials management and supply chain. When a patient needs a surgical dressing changed, the nurse goes to the supply room and grabs a new dressing without much thought about how it got there. As in many areas of healthcare, the materials management and supply chain community pushed for standardization for efficiency and cost savings. The first standard is that each institution has a Global Location Number (GLN) instead of an account number to make location of the institution easier. The second standard is that each product used in a facility has a Global Trade Item Number (GTIN) instead of a custom item number. It is thought that these standards will help by reducing errors in shipments, streamlining recall processes, enabling facilities to negotiate better contract pricing, and improving the supplier's ability to meet contract requirements. Electronic systems, with or without barcode scanning, can help make equipment use and tracking more efficient and help reduce costs (GS1 Healthcare US Location Identification Workgroup, 2012). These systems also make it easier to keep track of supplies on hand and assist with ordering supplies or materials as they are used.

Budget and Finance

Before the patient's chart can be finalized and closed, it is reviewed to make sure all coding is correct so that proper information is sent to the billing department. Some facilities do their own billing; others hire separate companies for this. If a patient is receiving care in the hospital, there are usually two separate billing processes. One is professional billing, which covers fees for services provided by surgeons, radiologists, and anesthesiologists. The other is hospital billing, which covers room and board and supplies. Incorrect billing can result in the claim's being denied by a patient's insurance company. This denial could leave either the patient or the hospital responsible for the bill, so there is usually a process for billers to submit appeals or resolve claim denials. It is a very complicated system that can be made easier through an electronic administration system.

Reimbursement rates for procedures and diagnoses change regularly, and a computerized contract management system helps facilities track rates of reimbursement and real-time changes in policies for different health insurance plans. Pay-for-performance systems will drive areas of reimbursement such as chronic disease management and care for acute disease without causing unnecessary harm (Miliard, 2015).

Financial systems within healthcare facilities can benefit greatly from use of an electronic system. They are responsible for sharing information between billing systems, materials management, and staffing/human resources in order to determine the financial health of the facility. The data provided is crucial for making strategic decisions about a healthcare institution and in planning organizational budgets. Executives and managers can view financial information

over both short- and long-term time frames and adjust their resources and fiscal planning appropriately.

Quality Assurance and Utilization Reviews

Computerized systems facilitate the tracking of patient outcomes. Unexpected or poor patient outcomes can be tracked by risk management (the legal department of a health system). Quality outcomes information can also be easily tracked. Outcome tracking helps identify faulty processes and assists in modifying policies and procedures to improve patient outcomes for a particular diagnosis or department within a health organization. Using CDSS and quality improvement efforts, health centers can build in best practice protocols to improve blood pressure management or

standardized risk assessment tools to improve patient care and outcomes (Miliard, 2015).

Accreditation

The availability of quality metrics will make it easier to meet and document the requirements of regulatory agencies. Agencies such as the Centers for Medicare and Medicaid Services and The Joint Commission implement policies that health facilities must follow in order to receive reimbursement by many health insurance plans. There are also smaller yet still important standards that must be maintained for certification, such as trauma status from the American College of Surgeons or stroke center status from The Joint Commission. EHRs simplify the data-gathering process when each of these agencies reviews a facility for accreditation.

REVIEW Clinical Decision Support Systems

RELATE Link the Concepts and Exemplars

Linking the exemplar of clinical decision support systems to the concept of cellular regulation:

1. Discuss how clinical decision support systems could improve outcomes for patients with cancer.
2. Name three cancer screening tools that could be built into an EHR.
3. Discuss the benefits of making reminders for cancer screening available to healthcare providers and to patients.

Linking the exemplar of clinical decision support systems to the concept of health policy:

4. You are working in the operating room, and your supervisor always requires that the employees in the department enter a higher level-of-diagnosis code on each trauma patient's chart. What are some ramifications?

5. What impact does a change in a federal or state health policy have on clinical decision support systems?

REFER Go to Pearson MyLab Nursing and eText

REFLECT Apply Your Knowledge

You are the nurse manager for an orthopedic unit that has just installed an EHR system with an administrative system. You have been short-staffed for several months.

1. How can an administrative system help get more nursing positions approved for your unit?
2. What other features of an administrative system do you think will have the greatest impact on your unit and why?

Exemplar 48.B

Individual Information at Point of Care

Exemplar Learning Outcomes

48.B Analyze individual information at point of care as it relates to informatics.

- Summarize the advantages of point-of-care service delivery.
- Outline uses of computer-based patient records in community and hospital settings.

Exemplar Key Terms

Case managers, 2823
Point of care, 2822

Overview

Studies have proven that the more direct nursing care a patient receives, the better the quality and safety of the care that is delivered and the more satisfied both nurse and patient are with the care. Nurses have reported that charting is an activity that consumes much of their time and takes time away from the bedside. The ability to enter data into a

patient's chart while at the patient's bedside seems like a valid compromise. Most EHRs allow recording of vital signs, medication documentation, assessment notes, and responses to nursing intervention (**Figure 48-4** »). One of the selling points of an EHR is that charting at point of care is possible and that it helps to increase efficiency. Interventions at **point of care** refers to interventions or testing that takes place

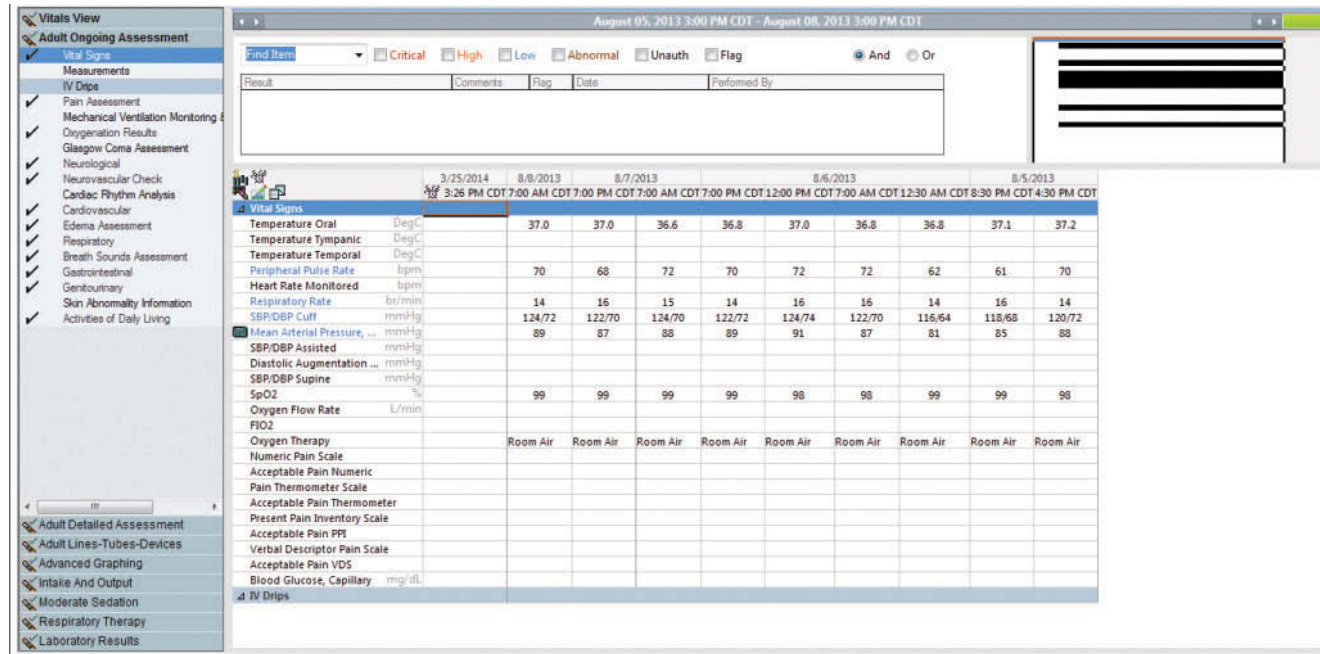

Figure 48-4 » This EHR screen displays the patient's vital signs. They can be entered by the nurse (or anyone with security rights to do so) at the bedside, and they can be displayed wherever needed.

using transportable, portable, or handheld devices near the patient (ASC Quality Collaboration, 2013). This setup provides on-the-spot information about the patient rather than having to wait for the results from blood or urine samples sent to the laboratory.

Computer-based Patient Records

Although the EHR has the potential to forever change how healthcare is delivered in the United States, it is important to understand that, in many instances, the electronic record cannot and should not replace real-time (face-to-face or telephone) communication with peers, other health professionals, and especially the patient. An acute change in the patient's condition still requires a phone call to the physician. News of pathology reports that indicate cancer should still be delivered in person by the physician and not discovered by the patient online. As systems become more advanced and interfaces more integrated, nurses must not lose sight of the human element in the delivery of care.

Patient Monitoring and Computerized Diagnostics

Advances in electronic systems are changing monitoring and tracking of patient care. Many facilities now use systems that allow electronic transmission of information such as the weight from the scale on the bed, intravenous pump rates, barcode scanning of medications that are administered, vital sign information, barcode scanning of blood administration, and ventilator settings. Many departments within a hospital or other facility may enter data about the patient into the record so that all practitioners have the information easily available rather than having to flip through a paper chart. Some examples are the laboratory

and many radiologic exams, such as MRI and CT scans (**Figure 48-5** »). With some systems, the radiologic image is available at the bedside in addition to the radiologist's report. The patient's medical administration record (MAR) also may be viewed by all providers involved in care of the patient (**Figure 48-6** »).

Community and Home Health

More than 4 million people are admitted to or reside in nursing homes and skilled nursing facilities annually; another 1 million reside in assisted living communities (CDC, 2015). In 2013, nearly 5 million patients received some degree of home healthcare (Harris-Kojetin et al., 2016). Nurses are the main providers of this care to patients, many of whom are receiving home healthcare for a chronic disease such as diabetes or congestive heart failure. It is difficult sometimes to stay current with the management of complex medical issues that home healthcare nurses are facing. The incorporation of current evidence-based clinical practice guidelines into the EHR system that is used by the home healthcare agency can improve the quality of care that these patients receive.

Case Management

Case managers help manage the care of certain patient populations, including patients with chronic medical conditions, such as diabetes; patients recovering from acute conditions, such as those receiving joint replacement; and patients managing psychiatric disorders. EHRs can assist the case manager by allowing trending of patient progress, documentation of patient education, and observation of quality metrics to help decrease readmission rates for these populations. EHRs also allow improved coordination of care between providers because they are all working off of one chart.

Figure 48-6 This EHR screen shows a medication administration record (MAR) for several regularly scheduled medications. The worksheet displays the next time the medications are scheduled to be administered.

Patient Education

Instructions for health conditions and procedures are available in most EHR systems. The patient's health problem can be identified through menus and educational information printed so that the nurse can review the information with the patient or the patient's family. Standardization of the record means that the patients will receive the same educational material whether they are being treated in the emergency department, on a surgical unit, or in a healthcare provider's office. The information contained within the educational material should be current and evidenced based, so that the task of patient

education is more accurate and meaningful. Some material may provide links to websites for additional information. Many systems can print out or be linked to educational information in different languages as well (Agency for Healthcare Research and Quality, 2016; National Learning Consortium, 2012). Note that use of standardized printed material does not negate the nurse's responsibility to (a) assess the patient or family member's ability to read and understand the information, (b) review the information in person with the patient or family member, and (c) ensure that the patient or family member understands the information prior to discharge.

REVIEW Individual Information at Point of Care

RELATE Link the Concepts and Exemplars

Linking the exemplar of individual information at point of care with the concept of assessment:

1. Discuss the advantages of being able to document the assessment of your patient at the point of care with an electronic record rather than a centralized charting location.
2. Explain how point-of-care documentation of your patient assessment can be used as an opportunity for patient teaching.

Linking the exemplar of individual information at point of care with the concept of oxygenation:

3. What point-of-care information can you obtain from an electronic medical record about the patient's past and present oxygenation status that may influence immediate nursing interventions?

4. How might point-of-care recording of pulse oximeter values have an advantage over recording them from a centralized monitoring station in the intensive care unit?

REFLECT Apply Your Knowledge

You are caring for an Albanian patient who just had his appendix removed. You log into your health system's electronic record to obtain discharge information. The patient and the family speak limited English. Albanian is not a language choice for appendectomy discharge instructions.

1. What are some options that you can use to try to educate the patient on taking care of his incision site?
2. How would you document your interventions in the electronic record?

Module 49

Legal Issues

Module Outline and Learning Outcomes

The Concept of Legal Issues

Sources and Types of Laws

49.1 Analyze the sources of laws and types of laws.

Tort Law

49.2 Analyze tort law and its implication for nursing.

Concepts Related to Legal Issues

49.3 Outline the relationship between legal issues and other concepts.

Strategies to Prevent Incidents of Professional Negligence

49.4 Outline strategies to prevent incidents of professional negligence.

The Standard of Care

49.5 Analyze the impact of the standard of care on legal issues.

Selected Laws That Affect Nursing Practice

49.6 Outline laws that affect nursing practice.

Lifespan Considerations

49.7 Differentiate considerations related to legal issues throughout the lifespan.

Legal Issues Exemplars

Exemplar 49.A Nurse Practice Acts

49.A Analyze nurse practice acts as they relate to legal issues.

Exemplar 49.B Advance Directives

49.B Analyze advance directives as they relate to legal issues.

Exemplar 49.C Health Insurance Portability and Accountability Act

49.C Analyze HIPAA as it relates to legal issues.

Exemplar 49.D Mandatory Reporting

49.D Analyze mandatory reporting as it relates to legal issues.

Exemplar 49.E Risk Management

49.E Analyze risk management as it relates to legal issues.

>> The Concept of Legal Issues

Concept Key Terms

Administrative laws, 2828	Competency, 2834	Expressed consent, 2834	Informed consent, 2833	Standards of care, 2831
Assault, 2831	Controlled Substances Act (CSA), 2835	False imprisonment, 2831	Law, 2828	Statute of limitations, 2830
Battery, 2831	Crime, 2829	Foreseeability, 2829	Liability, 2829	Statutory laws, 2828
Breach of duty, 2829	Criminal law, 2829	Good Samaritan laws, 2835	Malpractice, 2827	Tort, 2829
Causation, 2829	Damages, 2830	Implied consent, 2834	Negligence, 2829	Whistleblower, 2836
Civil law, 2829	Duty, 2829		Seven Rights, 2832	Whistleblowing, 2836

Legal issues in nursing encompass the rights, responsibilities, and scope of nursing practice as defined by state nurse practice acts and as legislated through criminal and civil laws. All patients have a privilege, demand, or claim by virtue of law or *right* (that which is proper or just) to expect competent nursing services. The nursing student must be equipped to provide safe nursing care consistent with legal requirements and to gain an awareness of ways to minimize the risks of errors due to accident, carelessness, system failures, or malpractice.

Malpractice is conduct that deviates from the standard of practice dictated by a profession. According to the 2012 Annual Report of the National Practitioner Data Bank, professional nurses were responsible for 6167 malpractice payments from 2003 to 2012. That is 4.2% of malpractice payments made during that time period (Health Resources and Services Administration [HRSA], 2014a). The number of nursing malpractice cases is associated with both the liability risks of nursing practice and an increasingly well-informed patient base.

» **Stay Current:** The National Practitioner Data Bank is an excellent source of research and information on healthcare and nursing topics. Visit their website at www.npdb.hrsa.gov for more information.

Providing safe care in light of these realities requires the nurse to have more than just a knowledge of anatomy and physiology, pathophysiology, and medications and therapies. It also requires knowledge of the regulations of healthcare providers, institutions, payment systems, and federal and state laws that are interconnected within the domain of the healthcare system. Upon enrollment, the nursing student begins learning about laws and regulations that affect nursing practice. Legal and professional regulations address both nursing practice and the practices of healthcare organizations that serve as workplaces for nurses at all levels of practice. Many healthcare agency policies and procedures exist to ensure that relevant laws are followed (1) to promote patient safety and reduce the risk for errors resulting in adverse events and (2) to protect both healthcare staff and healthcare agencies as a whole. For example, policies regarding identifying and managing patient valuables help ensure that patients' belongings are cared for and respected and also act to prevent theft or accidental loss.

To provide safe, effective care and maintain personal protection from liability, nurses must be aware of the applicable regulations they must follow in every nursing encounter. Awareness begins with understanding general legal concepts and continues as the nursing student starts to learn about the laws and regulations that directly affect the daily activities of nursing.

Sources and Types of Laws

Guido (2014, p. 2) defines **law** as the “sum total of the rules and regulations by which a society is governed.” Law is made at the federal, state, and local levels to reflect the ever-changing needs and expectations of a society. **Statutory laws** are made by the legislative branches of the government, including the U.S. Congress, state legislatures, and city and county governments. The U.S. Constitution grants the federal government power to make laws; the states have inherent power to act to maintain health, public order, safety, and welfare except where the Constitution restricts their ability to do so.

Nursing laws are examples of state statutory laws. Each state has a nurse practice act that contains the laws pertaining to nursing practice in that state. Nurse practice acts are discussed in detail in Exemplar 49.A. Other statutory laws that affect the practice of nursing include statutes of limitation, protection and reporting laws, natural death acts, and informed consent laws.

A legislative body, through statutory law, delegates the responsibility for the administration and enforcement of those laws to administrative agencies. Administrative agencies may be granted additional power to interpret those laws and enact policies or procedures by which those laws will be implemented and enforced. These policies or procedures are often referred to as **administrative laws**. State Boards of Nursing are examples of administrative agencies that are delegated the power to interpret and enforce law by the legislatures that govern them.

An overview of the sources of law is shown in **Figure 49-1** »». Selected categories of law that may affect nurses are shown in **Table 49-1** »».

Figure 49-1 »» Overview of the sources of law.

TABLE 49-1 Selected Categories of Laws Affecting Nurses

Category	Examples
Constitutional	Due process Equal protection
Statutory (legislative)	Nurse practice acts Good Samaritan acts Child and adult abuse laws Advance directives Sexual harassment laws Americans with Disabilities Act
Criminal (public)	Homicide, manslaughter Theft Arson Active euthanasia Sexual assault Illegal possession of controlled drugs
Contracts (private/civil)	Nurse and patient Nurse and employer Nurse and insurance provider Patient and agency
Torts (private/civil)	Negligence/malpractice Libel and slander Invasion of privacy Assault and battery False imprisonment Abandonment

Both criminal and civil laws have implications for the practicing nurse. **Criminal law** defines conduct that is harmful to another individual or to society as a whole and that may be punishable by fines or imprisonment. A **crime** is an act prohibited by statute or by common-law principles. Crimes are considered to be committed against the state rather than the individual. Examples of crimes include homicide, theft, and manslaughter. Crimes are classified by severity, more serious crimes being classified as *felonies* and lesser offenses being termed *misdemeanors*. Criminal laws are enforced by law enforcement and government prosecutors.

Civil law deals with the rights and duties of private individuals or citizens and is most often enforced through lawsuits. A **tort** is a civil wrong committed against an individual or an individual's property. An individual who violates tort law may be sued and compensation awarded to those wrongfully injured by those violations. Torts may be intentional or unintentional.

Tort Law

Tort law defines and addresses unintentional and intentional actions or omissions that result in harm to another person or persons or harm to another's personal property. Unintentional torts discussed here include negligence and malpractice. Intentional torts include assault, battery, false imprisonment, and invasion of privacy.

Unintentional Torts

It is especially important for nurses and other healthcare providers to understand negligence and malpractice.

Negligence

Negligence is conduct that deviates from what a reasonable person would do in a particular circumstance. The "reasonable person" standard describes an individual in society who exercises average care, skill, and judgment in conduct as a comparative standard for determining liability. According to this standard, an individual who undertakes a particular activity is ordinarily considered to have the knowledge common to others who engage in that activity; for example, a motorist must know the rules of the road. A negligent act occurs when an individual damages the person or property of another without any intent to injure. This damage may be due to carelessness on the part of the individual who committed the act. For example, a motorist who is talking on a cell phone or otherwise not paying attention and causes an automobile crash by failing to stop at a stop sign may be considered negligent and would be liable for any damages to any person or property.

In a legal action to establish negligence, the injured party needs to prove that the other party had a *duty of reasonable care*, that the other party *did not maintain reasonable care*, and that the failure to maintain such reasonable care *caused* (resulted in) *injuries* to the aggrieved party. In the example of the automobile crash, all drivers have the duty to operate their vehicles safely and follow traffic laws. If a driver fails to do so and this failure results in injury to any other person or damage to property, that driver would meet all of the criteria to be held negligent and would therefore be accountable for paying damages to the injured party.

Malpractice

When discussing negligence, it is important to note that the standard of a "reasonable person" is different for individuals in specific professional occupations. If an individual engages in an activity that requires special skills, education, training, or licensure—such as piloting a plane or providing professional nursing care—the standard by which that person's conduct is measured is the conduct of a reasonably skilled, competent, and experienced individual who is a qualified member of the group that is authorized to engage in that activity (**Box 49-1** [»](#)). Should an individual fail to meet the standard of conduct for his or her profession, this failure may be considered an instance of *professional negligence*, also known as *malpractice*.

Malpractice includes acts and omissions committed by a professional in the course of performing his or her professional duties. Malpractice is one of the most important areas of the law for nurses, because any negligent act or omission, however unintentional, may rise to the standard of malpractice and may jeopardize the professional nurse's license and, more importantly, patient safety. It is also important to remember that anyone who performs the special skills associated with a particular profession, whether qualified or not, is held to the standards of conduct of those who are properly qualified to do so, because the public relies on the special expertise of those who engage in such activities. Thus, a nursing student is held to the same standard of conduct as an experienced, licensed professional nurse.

Elements of Professional Negligence or Malpractice

Five elements of professional negligence or malpractice are required to establish **liability**, which is defined as the state of being legally obliged and responsible:

- The patient must be owed a **duty**, a legally enforceable obligation to adhere to a particular standard of care (Guido, 2014). The formation of a provider–patient relationship is the basis for finding that the healthcare provider owes a duty to the patient. A nurse–patient relationship begins when the nurse accepts responsibility for providing nursing care to a patient (North Carolina Board of Nursing, 2012).
- A deviation from the standard of care owed to the patient, called a **breach of duty**, must occur by either commission or omission. For example, the nurse has a duty to correctly administer medication to a patient. Giving the patient the wrong dose of medication would be a breach of duty.
- The element of **foreseeability** (certain events may reasonably be expected to cause specific results) must be present. The nurse should know in advance, or reasonably anticipate, that damage or injury will probably ensue from acts or omissions.
- The injury must have resulted as a direct result of the professional's breach of duty, called **causation**. Typically, a patient cannot successfully make a claim for malpractice on acquiring a healthcare-associated infection. Only if the patient could show that a specific nurse did not follow the standard of aseptic technique would the standard of causation be met.

Box 49–1

Categories and Examples of Negligence That Result in Malpractice

Failure to Follow Standards of Care

Failure to:

- Perform a complete admission assessment or design a plan of care.
- Adhere to standardized protocols or institutional policies and procedures (e.g., using an improper injection site).
- Follow a physician's verbal or written orders, if appropriate.

Failure to Use Equipment in a Responsible Manner

Failure to:

- Follow the manufacturer's recommendations for operating the equipment.
- Check the equipment for safety prior to use.
- Place the equipment properly during treatment.

Failure to Communicate

Failure to:

- Notify a physician in a timely manner when conditions warrant it.
- Listen to a patient's complaints and act on them.
- Communicate effectively with a patient (e.g., providing inadequate or ineffective communication of discharge instructions).
- Seek clarification of orders for treatment when necessary.
- Discuss medication errors with team and patient.

Failure to Document

Failure to note in the patient's medical record:

- A patient's progress and response to treatment.
- A patient's injuries.
- Pertinent nursing assessment information (e.g., drug allergies).
- A physician's medical orders.
- Information about telephone conversations with physicians, including time, content of communication between nurse and physician, and actions taken.

Failure to Assess and Monitor

Failure to:

- Complete a shift assessment.
- Implement a plan of care.
- Observe a patient's ongoing progress.
- Interpret a patient's signs and symptoms.

Failure to Act as a Patient Advocate

Failure to:

- Question discharge orders when a patient's condition warrants it.
- Question incomplete or illegible medical orders.
- Provide a safe environment.

Sources: From Anselmi, K. K. (2012). Nurses' personal liability vs. employer's vicarious liability. *MEDSURG Nursing*, 21(1), 45–48; Reising, D. (2012). Make your nursing care malpractice-proof. *American Nurse Today*, 7(1), 24–28; Tzeng, H.-M., Yin, C. Y., & Schneider, T. E. (2013). Medication error-related issues in nursing practice. *MEDSURG Nursing*, 22(1), 13–16, 50.

- The plaintiff must demonstrate that some type of physical, financial, or emotional injury or harm resulted from the breach of owed duty. If the nurse gave the wrong medication but no harm occurred, the elements are not present for malpractice.

SAFETY ALERT Nurses administering medications must know why the patient is receiving the medication, the acceptable dosage range, possible adverse effects, toxicity levels, and contraindications.

The basic purpose of a malpractice lawsuit is to award damages sufficient to restore the plaintiff to his or her original position, as far as is financially possible. The amount of the **damages**, or compensation, for the plaintiff's loss or injury may include enough money to pay for the plaintiff's medical fees associated with the injury. If the plaintiff lost the ability to work as a result of the injury, damages could include compensation for lost wages as well as for medical fees. Punitive damages may be awarded if the nurse's misconduct is deemed malicious, willful, or wanton (Guido, 2014). Punitive damages are considered punishment for misconduct (Sleasman, 2013).

Related Doctrines

Several legal doctrines, or principles, are related to negligence and malpractice. One such doctrine is *respondet superior* ("let the master answer"). A lawsuit for a negligent act or omission performed by a nurse generally will also

name the nurse's employer. Employers may also be held liable for negligence if they fail to provide adequate human and material resources for nursing care, fail to properly educate nurses on the use of new equipment or procedures, or fail to orient nurses to the facility. Another doctrine is *res ipsa loquitur* ("the thing speaks for itself"). In some cases, the harm cannot be traced to a specific healthcare provider or standard but does not normally occur unless there has been some type of negligence. An example is harm that results when a surgical instrument is inadvertently left in a patient during surgery.

Statute of Limitations

There is a limit to the amount of time that can pass between recognition of harm and bringing a suit. This is referred to as the **statute of limitations**. The exact time limitation varies by type of suit and state, but plaintiffs typically have 1 to 2 years from the time that they knew of the injury or had reason to believe that an injury was sustained to file a malpractice lawsuit. Statutes of limitations applying to minors vary from state to state; some states identify specific variances such as extended time limits for specific types of injuries.

Intentional Torts

A number of intentional torts—actions taken by an individual with the intent to perform the action—have a bearing on nursing practice. The willful nature of these actions and the intent behind them separate intentional torts from negligence and malpractice.

Assault, Battery, and False Imprisonment

Assault is the action of creating an apprehension of offensive, insulting, or physically injurious touching. Assault can occur without an individual's actually being touched. Threatening a patient who refuses to agree with starting an intravenous line is assault. **Battery**, on the other hand, is defined as willful touching of another individual (or the individual's clothes or even something the individual is carrying) that is unwanted, embarrassing, or unwarranted, such as touching done without permission or giving an injection without a patient's consent. Even the simple act of ambulation requires the patient's consent. Forcing a patient to ambulate against his or her will may be considered battery (Guido, 2014).

Guido (2014) defines **false imprisonment** as the "unjustifiable detention of a person without legal warrant to confine the person." False imprisonment includes confining the patient to his or her room or restraining the patient to the bed with the intent to restrict or prevent the patient's freedom. Detaining a patient who wishes to leave against medical advice is generally considered false imprisonment.

Because **standards of care** (the skills and learning common to their profession, including the nursing process) prohibit nurses from forcing patients to participate in treatment or to engage in any action against the patient's will, assault, battery, and false imprisonment are actions that violate standards of care and may rise to the level of civil or criminal action against the nurse.

Invasion of Privacy

According to the Fourth Amendment to the U.S. Constitution, individuals have the right to privacy. Information concerning patients is confidential and may not be disclosed without authorization. The patient's right to privacy extends to use of the patient's name as well as photographic or videographic representations of the patient (e.g., the patient's picture may not be used without proper authorization). This right extends to control of the patient's personal belongings, personal space, and immediate territory. The nurse-patient relationship is based on trust. Searching a patient's room, touching personal belongings without first requesting permission, and entering a patient's room without knocking are behaviors that potentially violate this trust. Most healthcare agencies have policies and procedures that specify to whom and under what circumstances patient information can be released, and they have appropriate procedures for managing patient environments and personal property within the agency. Failure to follow these policies could lead to a claim of invasion of privacy.

Nurses are bound by the Privacy Rule of the Health Insurance Portability and Accountability Act (HIPAA) to protect the privacy of the patient's protected health information. This includes information related to mental and physical conditions, healthcare services provided, and payment for services rendered. It also includes name, address, birth date, and Social Security number (McGowan, 2012). HIPAA protections represent the minimum requirements for privacy. State law and professional codes may afford additional protections, in which case the more strict law is enforced. HIPAA and the Privacy Rule are discussed in more detail in Exemplar 49.C.

Concepts Related to Legal Issues

Safety and legal issues are closely connected. Ensuring patient safety and preventing care errors have important legal implications for nurses, as well as implications for the health of their patients. As many as 1 in 10 patients experience adverse events, such as falls and infections, during hospital stays; approximately 15% of these events involved medication errors (Tzeng, Yin, & Schneider, 2013). Prevention measures are essential for reducing these events; equally important is properly reporting any errors that do occur. Proper reporting can minimize the impact errors have on patients and help organizations and individuals gain valuable insight into the causes of errors. Unfortunately, nurses sometimes do not report errors. If uncovered later on, these errors and the subsequent failure to report could have professional and legal ramifications.

Issues of consent are important for all nurses but present special considerations in managing care. Nurse managers must adhere to legal requirements related to safety, communication, and many other areas; they must also ensure that other members of the care team follow these requirements. When requirements are not followed by team members, the nurse manager must identify and correct the situation. In addition, managers must ensure that patient care tasks are delegated appropriately to licensed and unlicensed staff and that these tasks are carried out correctly and completely according to state nurse practice acts and facility policy.

The Concepts Related to Legal Issues feature outlines some of the many ways in which legal issues intersect with other concepts. The concepts are presented in alphabetical order.

Strategies to Prevent Incidents of Professional Negligence

Situations may arise in nursing practice that can lead to reported negligence or malpractice cases. A continuing issue in nursing is medication errors, which must be clearly documented and discussed with the patient (Tzeng et al., 2013). Other situations in which problems may arise include communicating care concerns and key information about the patient's condition; ensuring that physicians' orders are clear; understanding how to use equipment in practice; and providing appropriate mentoring, assessment, and care plans for patients (Anselmi, 2012; Lipley, 2012).

Maintaining Patient Safety

Patients often fall accidentally, which sometimes results in injury. Some falls can be prevented through appropriate use of bed alarms, side rails, and other safety measures. If a nurse fails to take appropriate measures to prevent patient injury, that nurse may be held liable for malpractice if the patient falls and is injured as a direct result. Most hospitals and nursing homes have policies regarding the use of safety devices. The nurse needs to be familiar with these policies and needs to take the indicated precautions to prevent injuries (see the modules on Mobility and Safety).

SAFETY ALERT Assess every patient for fall potential. Document all nursing measures taken to protect the patient (e.g., "Instructed patient how to use the call light").

Concepts Related to Legal Issues

CONCEPT	RELATIONSHIP TO LEGAL ISSUES	NURSING IMPLICATIONS
Cognition	Patients demonstrate the capacity to understand the benefits, risks, and alternatives for care. If this capacity exists, consent must be given voluntarily.	<ul style="list-style-type: none"> ■ Provide information about procedures and conditions appropriate to the patient's cognitive level. ■ Work with the care team to assess the patient's capacity to give consent. ■ Assist the patient with consent forms and answer any questions the patient may have. ■ Work with the surrogate decision maker if the patient lacks the capacity to provide consent.
Comfort	Patients have the legal right to receive appropriate end-of-life (EOL) care. All hospitals receiving Medicare and Medicaid funds are legally responsible to provide advance directive information and support patients' advance directive needs.	<ul style="list-style-type: none"> ■ Assess own assumptions or biases surrounding EOL care. ■ Assess self-understanding of appropriate EOL care options in your practice area. ■ Ask for support from supervisor or peers to assist in advocating for appropriate EOL care. ■ Anticipate further assessment of information patients and family members may need. ■ Be aware that advance directives (ADs) improve the EOL planning process by giving patients peace of mind and easing family conflict during health crises.
Communication	Nurses must ensure the privacy of all patient information during all care and in all care areas and must follow HIPAA regulations.	<ul style="list-style-type: none"> ■ Ensure that patient information, such as online charting, is accessible only for appropriate use by appropriate staff members. ■ Discuss with your patients how you ensure privacy. ■ Ensure that patient care is discussed only with appropriate individuals and not outside the care unit.

In some instances, ignoring a patient's complaints can result in malpractice. This type of malpractice is termed *failure to observe and take appropriate action*. For example, the nurse who does not report a patient's complaint of acute abdominal pain is negligent and may be found liable for malpractice if the patient's appendix ruptures and the patient dies. If a nurse fails to take the blood pressure and pulse and to check the dressing of a patient who has just had cardiac surgery, the nurse is omitting important assessments. If the patient hemorrhages and resulting brain hypoxia renders the patient unable to return to his or her former occupation, the nurse may be held liable for injury and loss of wages.

Incorrect identification of patients is a problem, particularly in busy hospital units. Unfortunate occurrences, such as removal of a healthy gallbladder from the wrong patient, have resulted from nurses preparing the wrong patient for surgery. Cases of mistaken identity are costly and possibly very painful for the patient and render the nurse liable for malpractice.

Using Effective Communication

Nurses interact with patients and families during the provision of care. Poor communication skills may create a perception in the patient that the nurse is less than competent. Poor communication coupled with a negative outcome can increase the chance of a malpractice claim. Clear communication of directions and explanations and provision of effective patient education regarding the patient's healthcare requirements can help decrease the risk of bad outcomes (see the module on Teaching and Learning). Attentive listening

skills demonstrate the element of caring. Accurate documentation and reporting (see the module on Communication) provide a source of information that will either support or refute allegations of malpractice. Nursing documentation should be completed according to policy and should clearly depict the timeline of care, including assessments, interventions, the patient's response to interventions, and notification of information outside treatment protocol (e.g., abnormal lab values, changes in patient assessment). Remember that this document serves as the legal record of what occurred, so the nurse should document defensively, be inclusive, and not rely on their own or the patient's memories of the details of care.

Minimizing the Risk of Medication Errors

Administration of medications has been identified as a high-risk activity for error. Prevention of medication errors requires a systems approach involving all interprofessional healthcare personnel. Nurses need to strictly apply the **Seven Rights** of medication administration:

1. **Right assessment**
2. **Right drug**
3. **Right dose**
4. **Right patient**
5. **Right route**
6. **Right time**
7. **Right documentation.**

Strategies that integrate new technology, such as barcoding and electronic records, need to be evaluated for effectiveness in reducing errors.

Nothing can replace nursing judgment in preventing errors in administering medications. Unclear orders need to be clarified. Questions need to be answered. The nurse needs to have knowledge of each medication prior to administration. A culture of safety instead of blame will facilitate identification of errors and evaluation of causes and strategies to reduce errors.

Obtaining Professional Liability Insurance

Nurses, like physicians, should carry professional liability insurance to manage their personal financial risk. Occurrence-based coverage covers incidents that occurred during the time period the policy was in effect, regardless of whether the policy was still in effect when the claim was made. Claims-made policies provide coverage only if the incident occurred and the claim was reported during the active policy period. Policies should identify limits of liability, declarations, deductibles, exclusions, reservation of rights, covered injuries, defense costs, coverage conditions, and supplementary payments.

Policies may be individual, group, or employer sponsored. Individual coverage provides the broadest coverage to the policyholder. This type of policy covers the named policyholder on a 24-hour basis as long as his or her actions fall within the scope of practice. Employer-sponsored coverage provides the narrowest coverage for the individual nurse; the policy covers only actions performed during work as an employee of the institution. Nursing students are generally required to carry liability insurance for the duration of the education program, although some programs insure students under a broad institutional policy.

The Standard of Care

The applicable state nurse practice act and administrative rules form the basis of the standard of care to which each nurse is held. They define professional conduct and the scope of practice for the licensed nurse and identify activities for all levels of personnel providing nursing care. These laws are not static, and every nurse needs to be aware of any changes. The nurse's specific job description will contribute to defining the standard of care. Employers can limit but not expand the scope of practice, and the nurse is held to functioning within the scope of employment.

Although agency policies and procedures may seem to contain overwhelming amounts of information, they serve to define the standard of care. The prudent nurse reviews and implements the policies and procedures relevant to her or his practice. If there is a conflict between current practice and policy, the nurse should be proactive in resolving the conflict through quality improvement processes (see the module on Quality Improvement).

A primary source for defining the standard of care is the prevailing national nursing standards. These include the American Nurses Association (ANA) Standards of Practice as well as specialty practice standards appropriate to a nurse's practice (e.g., standards for critical care nurses).

Nurses who follow these standards will provide their patients with the best care possible and minimize the likelihood of committing any unintentional act that may rise to the level of malpractice.

Selected Laws That Affect Nursing Practice

In addition to tort laws, a number of other laws affect nursing practice. These include laws related to informed consent and competency, as well as laws regarding the Controlled Substance Act and the Good Samaritan Act. Because states have the freedom to enact additional legislation that may further define or restrict aspects addressed by federal law, all nurses should be aware of the laws that govern or affect nursing practice in their own states.

Informed Consent

Informed consent refers to the patient's legal and ethical rights to be informed of, and give or refuse permission for, any healthcare procedure or treatment. The healthcare provider has the duty to disclose information about proposed treatment in terms the patient can reasonably understand. The healthcare provider must also disclose information about available alternatives, the risks and benefits of each treatment option, and the patient's right to refuse treatment.

General guidelines regarding the information that should be provided to the patient include the following:

- The diagnosis or condition that requires treatment
- The purposes of the treatment
- What the patient can expect to feel or experience
- The intended benefits of the treatment
- Possible risks or negative outcomes of the treatment
- Advantages and disadvantages of possible alternatives to treatment (including no treatment).

To give informed consent voluntarily, the patient must not be coerced or pressured in any manner. For example, if the patient is motivated to consent by fear of disapproval on the part of a healthcare provider, such consent is not considered to be voluntary.

Patient understanding is an essential element of informed consent. Technical words and language barriers can inhibit understanding and, when a patient has a lower literacy level, may encourage a signature without discussion of its actual meaning. Therefore, cultural competence in managing patient care is critical (Agency for Healthcare Research & Quality [AHRQ], 2012). If a patient cannot read, the healthcare provider must read the consent form to the patient, and the patient must state an understanding before signing the form. If the patient and the healthcare provider do not speak the same language, a medical interpreter must be present. However, even with an interpreter, it is important to remember that errors in translation may occur. The nurse should also consider the patient's cultural and spiritual preferences when asking a patient to make decisions about a procedure or treatment. Some religions and some cultures have specific mores that affect healthcare, although patients may or may not follow those mores (Arritt, 2014).

The nurse should follow the employing agency's specific protocols regarding informed consent. Obtaining informed consent for specific medical and surgical treatments is the responsibility of the individual who will perform the procedure. Consent must be obtained for all procedures and treatments, including nursing care. However, this does not require written consent before each occurrence. Most nurses rely on **expressed consent** (an oral or written agreement) or **implied consent** based on a patient's action. The patient either verbally indicates participation in the care or nonverbally takes actions that are consistent with the care. For example, patients who position their bodies for an injection or cooperate with the taking of vital signs are expressing implied consent. While state laws provide for protection from liability for failure to obtain informed consent, nurses need to understand implied versus obtained consent (Cole, 2012).

Competency for Consent

Competency is a legal presumption applied to individuals when they become adults. Competency gives adults the right to negotiate certain legal activities, such as making a will or entering into a contract. In most states, an individual is considered to be competent at 18 years of age unless some evidence to the contrary persuades a court to declare that individual incompetent.

Adults who have been declared legally incompetent through a court order are provided a legal guardian. The legal guardian should give healthcare providers a copy of the court order giving him or her the authority to make healthcare decisions on the other adult's behalf. Examples of adults who may be legally incompetent include those who have sustained a debilitating brain injury as a result of a motor vehicle crash and those who have profound intellectual disability.

Focus on Diversity and Culture

Cognitive Impairment and Informed Consent

Cognitively impaired adult patients present special particular concerns when it comes to informed consent. The presence of cognitive impairment does not automatically preclude a patient from giving consent, although some patients who have been declared legally incompetent by a court will have a legal guardian who must give consent. In determining whether a patient without a legal guardian is able to give informed consent, the patient's capacity to understand the benefits, risks, and alternatives for care and to make and communicate a decision must be considered (Vanderbilt Kennedy Center, 2016). This capacity can change over time and may be affected by the nature and complexity of the decision involved; therefore, the patient's capacity should be assessed and documented for each treatment. If a patient does not have the capacity to consent or it is unclear whether the patient has the capacity, decision making should be delegated to a surrogate, following agency procedure. Consent is required for elective and therapeutic surgeries, diagnostic procedures, and procedures that involve sedation or anesthesia. Consent is not required for time-sensitive, lifesaving emergency procedures (Vanderbilt Kennedy Center, 2016).

An adult may be rendered temporarily incompetent by narcotic medication or a serious fall or may gradually be rendered incompetent as a result of dementia. The nurse who has concerns about a patient's level of competency should alert the primary care provider. If the primary care provider determines that the patient is not competent for the purposes of informed consent, the provider will determine whether the emergency doctrine applies (see the Consent in an Emergency section below) or whether someone else can validly make healthcare decisions on the patient's behalf. State laws regarding consent for adults who are rendered temporarily incompetent vary. Courts generally presume continuing competency of adults unless the healthcare facility can show that the patient is unable to understand the consequences of his or her actions (Guido, 2014). All healthcare staff, including nurses, should be familiar with their state's laws and with the policies and procedures of their employing agency. Nurses should recognize the effect of issues related to competency on providing nursing care, because patients have the right to decline nursing care as well as medical procedures. The Focus on Diversity and Culture feature discusses how a patient's cognitive impairment may affect the process of obtaining informed consent.

Consent in an Emergency

In most states, the law assumes an individual's consent to medical treatment when the individual is in imminent danger of loss of life or limb and unable to give informed consent. In other words, the emergency doctrine assumes that the individual would reasonably consent to treatment if able to do so. This doctrine serves as a guiding principle that permits healthcare providers to perform potentially lifesaving procedures under circumstances that make it impossible or impractical to obtain consent. The emergency doctrine may not always apply. For example, it does not extend to allowing healthcare providers to implement a treatment or procedure to which the patient would not reasonably consent if the patient were able to do so. It also does not permit healthcare providers to provide a treatment or procedure that the patient previously refused. For example, if a patient has previously refused a procedure on religious grounds, healthcare providers may not implement the procedure if the patient becomes unconscious.

Child Participation in Healthcare Decisions

For a minor child (under age 18), a parent or guardian must give informed consent for medical treatment. Specific legal exceptions do exist, however, including situations in which the emergency doctrine applies, when the child is an *emancipated minor* (one who is no longer under parental control and manages his or her own financial affairs), when the child is a resident of a state that allows a *mature minor* to give valid consent (for example, 14- and 15-year-old adolescents who are able to understand treatment risks), when a court order to proceed with treatment exists, or when the law recognizes the minor as having the ability to consent to a specific treatment. In the majority of states, a minor who is the parent of a child may give informed consent for healthcare treatment of the child. Some states also permit teenagers of a certain age who are seeking certain types of care to do so without parental consent. Types of care that may not require

Box 49–2

Overview of Minor Consent Laws

Contraceptive Services

Twenty-one states and the District of Columbia allow all minors (age 12 years and older) to consent to contraceptive services. Twenty-five states allow only certain categories of minors to consent to contraceptive services.

Sexually Transmitted Infections Services

All states and the District of Columbia allow all minors to consent to services for sexually transmitted infections.

Prenatal Care

Thirty-two states and the District of Columbia explicitly allow all minors to consent to prenatal care.

Adoption

Twenty-eight states and the District of Columbia allow all minor parents to choose to place their child for adoption.

Medical Care for a Child

Thirty states and the District of Columbia allow all minor parents to consent to medical care for their child. The remaining 20 states have no relevant explicit policy or case law.

Abortion

Two states and the District of Columbia explicitly allow all minors to consent to abortion services. Twenty-one states require that at least one parent consent to a minor's abortion, while 13 states require prior notification of at least one parent. State laws regarding abortion may change; be sure to know the laws in your state.

Sources: Data from Guttmacher Institute. (2016b). *An overview of minors' consent law*. Retrieved from http://www.guttmacher.org/statecenter/spibs/spib_OMCL.pdf; Guttmacher Institute. (2016c). *Minors' access to contraceptive services*. Retrieved from https://www.guttmacher.org/sites/default/files/state_policy_overview_files/spib_macs.pdf; National District Attorneys Association. (2013, January). *Minor consent to medical treatment laws*. Retrieved from [http://www.ndaa.org/pdf/Minor%20Consent%20to%20Medical%20Treatment%20\(2\).pdf](http://www.ndaa.org/pdf/Minor%20Consent%20to%20Medical%20Treatment%20(2).pdf).

parental permission, depending on state law, include contraceptive services, prenatal care, mental health counseling, diagnosis and treatment of sexually transmitted infections, and treatment of substance abuse (American Civil Liberties Union [ACLU] of Ohio, 2014; Goodwin et al., 2012).

In some states, mature minors are permitted to give consent for treatment or to refuse treatment. In some cases, the minor must convince a judge that he or she is mature enough to make an independent judgment about consent for treatment. Nurses need to know the state and federal laws regarding consent as well as the agency's policies and procedures regarding informed consent (Brent, 2013). North Carolina law, for example, provides for all minors over the age of 12 to consent for contraceptive services, treatment of sexually transmitted infections, and prenatal care (Moore, 2015). For an overview of minor consent laws in the United States, see **Box 49–2** >>>.

Clinical Example A

Marvin Martinice, a 15-year-old boy with acute myelocytic leukemia, has come out of his second remission with an acute onset of fever, joint pain, and petechiae. A bone marrow transplant is one of the few remaining therapeutic options. Although Marvin has agreed to

a transplantation if a suitable donor is found, he does not want to be resuscitated and placed on life-support equipment should he go into a cardiac arrest. Marvin has talked extensively with the hospital chaplain and social worker and feels comfortable with his decision. His parents want an all-out effort to sustain his life until a donor is located.

Critical Thinking Questions

1. In general, what happens when parents and children have conflicting opinions about treatment?
2. Assume you are a nurse involved in Marvin's care. What is your role, if any, in addressing the difference of opinion between Marvin and his parents regarding available treatment options?

Controlled Substances Act

The **Controlled Substances Act (CSA)** is a federal law that requires drugs to be classified on the basis of the substance's medical use, potential for abuse, and safety risks. The classifications are referred to as schedules and are numbered from I to V; Schedules I and II have the highest potential for abuse (**Table 49–2** >>>). The CSA is enforced by the U.S. Drug Enforcement Agency, which regulates a closed system of distribution. This system provides for registration with unique identifiers for legitimate handlers of controlled substances and required record keeping that traces the flow of any drug from the time it is first imported or manufactured, through the distribution level, to the pharmacy or hospital that dispenses it, and then to the patient who receives it. Each state has its own requirements for prescribers. Nurses must abide by the rules and regulations of their state.

>>> **Stay Current:** For more information about the Controlled Substance Act, visit the Office of Diversion Control's website at www.deadiversion.usdoj.gov/21cfr/21usc.

Good Samaritan Laws

Most states have **Good Samaritan laws** that encourage healthcare providers to help victims in an emergency. These laws are designed to protect the healthcare worker from potential liability when volunteering his or her skills outside of an employment contract (**Figure 49–2** >>>). To be protected by Good Samaritan laws, a nurse must adhere to the standard of nursing.

Source: Jsteck/E+/Getty Images.

Figure 49–2 >>> Good Samaritan laws protect healthcare workers from liability when they volunteer their services in an emergency.

TABLE 49-2 U.S. Drug Schedules and Examples

Drug Schedule	Abuse Potential	Physical Dependence	Psychologic Dependence	Dependency Potential	
				Examples	Therapeutic Use
I	Highest	High	High	Heroin, peyote, marijuana, MDMA ("ecstasy")	Medical use of marijuana/cannabis limited to specific states
II	High	High	High	Morphine, opium, cocaine, oxycodone, fentanyl, methadone, amphetamine, pentobarbital	Current accepted medical use in the United States with severe restrictions; prescription required
III	Moderate	Moderate	High	Tylenol with codeine, anabolic steroids, buprenorphine, ketamine	Current accepted medical use in the United States; prescription required
IV	Lower	Lower	Lower	Alprazolam, clonazepam, lorazepam, midazolam, diazepam	Current accepted medical use in the United States; prescription required
V	Lowest	Lowest	Lowest	Cough medicine containing codeine, ezo-gabine	Current accepted medical use in the United States; no prescription required

ing care during all volunteer activities. The nurse should provide only care that is consistent with his or her level of training and licensure. Once having made the decision to render emergency care, the nurse is responsible for following through by providing the necessary care or safely placing the victim in the care of someone who can provide the appropriate care (Howie, Howie, & McMullen, 2012). Before volunteering their skills, nurses should review the nurse practice act and the Good Samaritan law in the state in which they work.

Whistleblowing Laws

Whistleblowing is the disclosure of an employer's unsafe or illegal practices and/or policies by an employee (Guido, 2014). The employee who reports such practices or policies is called a **whistleblower**. The Whistleblower Protection Act of 1989 establishes certain protections for individuals who report gross misconduct on the part of their employers to federal authorities; additional protections may vary by state. To qualify for protection under the federal act, the employee must make every effort to resolve the issue via the employer's internal reporting procedures before going outside of the organization. In addition, an employee does not qualify for protection under the act unless the employer has threatened or engaged in retaliation against the employee as a result of the employee's complaint.

Simple error or misconduct on the part of the employer does not qualify under the Whistleblower Protection Act. Typically, the activity or policy in question must violate a state or federal law or rule, and the employer must be aware that the activity or policy is a violation. Examples include billing fraud, failure to maintain safety equipment, and chronic insufficient staffing. The employee making the complaint must give the employer written notice and an appropriate amount of time to correct the issue. To be considered a whistleblower, the employee must also make or threaten to make a report to the appropriate state or federal agency.

Whistleblower laws exist to prevent retaliation by the employer against reasonable, good-faith reporting of illegal, unethical, or unsafe conduct in order to provide a safe environment for patients. However, the nurse who makes a report outside of the employing agency should be prepared for the possibility of negative consequences. These may include personal consequences such as losing the support or

friendship of coworkers. They may also include retaliatory or discriminatory actions, including dismissal, demotion, discipline, or intimidation. These actions are prohibited by the Occupational Safety and Health Act. To prevail in a discrimination claim, an employee must report discriminatory actions to the Occupational Safety and Health Administration (OSHA) before resigning from the place of employment.

Lifespan Considerations

Nurses should be aware of how legal issues may affect patients of different age groups and must understand their responsibilities for protecting their patients and themselves when these issues arise. No matter the age or condition of the patients with whom the nurse works, failure to keep up with changes in laws or regulations can endanger patients and place the nurse at risk for liability.

Legal Issues Pertaining to Infants and Children

Nurses are mandated reporters of child abuse or suspected child abuse, including physical, emotional, and sexual maltreatment. Although statutes related to reporting vary from state to state, nurses who fail to report abuse may face civil charges. Reports should be complete and accurate and should be made according to the policy of the organization for which the nurse works. In addition to reporting the abuse within the organizational framework, the nurse should personally report the abuse to the proper authorities. When abuse is reported, all pertinent information in the patient's medical record is required by law to be disclosed to the reporting agency. As such, reporting abuse or suspected abuse represents an exception to patient confidentiality rules (Merrick & Latzman, 2014).

Nurses should be aware of common signs of abuse in both infants and children. For example, bruising in infants can indicate physical abuse; vomiting, irritability, and lethargy may indicate head injury. Older children may exhibit unexplained injuries or bruises, injuries that do not match the explanations given, and untreated medical problems. Children and adolescents who report sexual abuse may exhibit no abnormal physical findings in an exam, though cultures may indicate the presence of sexually transmitted

diseases (STDs). If the parent or guardian of a child is responsible for the abuse, health history and interview information provided by that individual may be vague or intentionally misleading (Herendeen et al., 2014).

Accurate reporting of abuse and suspected abuse is essential for protecting the child and safeguarding the nurse both professionally and personally. The nurse is required to report the facts or circumstances that led to the belief that abuse occurred but does not have the burden of proof. Reports must be made in good faith and without malicious intent. Most states allow reports to be made anonymously but may encourage the reporter to provide identifying and contact information to aid in the investigation. In most states, if the reporter's identity is known, it is not disclosed to the individual suspected of committing the abuse (Child Welfare Information Gateway, 2016). Mandatory reporting is discussed further in Exemplar 49.D.

» Stay Current: Nurses should be familiar with the child abuse reporting statutes in their state. Search by state and topic at the U.S. Department of Health and Human Services' Child Welfare Information Gateway at <https://www.childwelfare.gov/topics/systemwide/laws-policies/state/>.

Legal Issues Pertaining to Adolescents

Confidentiality is a concern for some adolescents seeking care, particularly care related to contraception, sexual health, substance abuse, or mental health. Nurses should be familiar with federal and state laws related to adolescent confidentiality. Trust and honesty are essential. Nurses should ensure that patients understand that confidentiality will be maintained when possible but that confidentiality cannot be guaranteed in some circumstances. For example, if the patient is covered under a parent's or guardian's insurance, billing and benefits statements provided to the parent or guardian may include information about care. It is also important that patients understand that the authorities must be contacted if a patient is in imminent danger, if there is evidence of abuse, or if the patient has certain communicable diseases (American Academy of Family Physicians [AAFP], 2013).

Adolescent patients may wish to be examined or receive counseling separately from their parents. The nurse should make every effort to honor this request, though doing so may lead to confrontation with the parents. Understanding state statutes and organizational policy related to adolescent confidentiality is essential when situations such as this arise.

The use of electronic health records (EHRs) presents additional concerns about confidentiality for adolescents. In general, child and adolescent EHRs are set up with parents or guardians as proxy. As a result, these individuals are able to view information contained in the EHR. Some EHR systems offer customizable modules that can be configured to restrict the proxy's access to confidential or sensitive information; some systems do not. Certain information gathered during general exams—such as social or sexual history—may be accessible to parents or guardians via the EHR unless it is included with the restricted information. If the system does not allow for customization to restrict information, patients should be informed that parents or guardians can access these records (American College of Obstetricians and Gynecologists [ACOG], 2014).

When providing confidential care to adolescents, the nurse should encourage adolescents to consider involving parents or guardians in their decision making. The nurse should make it clear that this is a suggestion and not a requirement for receiving care. Patients who feel pressured to involve parents or who fear that their confidentiality may be breached may refuse treatment and may not receive the care they need.

Legal Issues Pertaining to Pregnant Women

Legal rights of pregnant women in the United States have been a subject of debate for many years. Perhaps the most famous example of this surrounds the Supreme Court's 1973 ruling in *Roe v. Wade*. In this ruling, the court deemed it unconstitutional for states to outlaw abortion during the first trimester of pregnancy and placed restrictions on states' ability to regulate abortion during the second and third trimesters. Since the ruling, abortion has remained a contentious issue in the United States. Statutes related to abortion vary from state to state and include regulations related to gestational limits, insurance coverage for procedures, and mandated counseling (Guttmacher Institute, 2016a).

In addition to statutes related directly to abortion, a number of states have passed fetal protection laws. The intent of these laws is to protect both mothers and fetuses and punish individuals who harm them. In some cases, however, these laws have raised questions about a woman's right to refuse certain tests or treatments during pregnancy (Graham, 2014).

Abortion and fetal protection laws may create ethical or moral dilemmas for nurses. It is of the utmost importance that nurses know their state's statutes and their organization's policies on these matters. In addition, nurses should understand their rights of conscientious objection and their responsibilities in the event that they choose to be a conscientious objector. Conscientious objection is the refusal by the nurse to engage in a procedure because doing so would violate his or her moral or ethical principles (Lachman, 2014). Abortion, sterilization, and contraception are reproduction-related procedures that may give rise to conscientious objection. Currently, 45 states allow individual healthcare providers to refuse to participate in abortions, and 42 states allow institutions to refuse to provide them (Guttmacher Institute, 2016). Nurses who choose to be conscientious objectors should make their refusal known in advance of the procedure to allow for necessary staffing adjustments. If advance notice is not possible, the nurse is duty bound to remain with the patient until another nurse can take over the patient's care. Failure to do so may be considered patient abandonment (Lachman, 2014).

Legal Issues Pertaining to Older Adults

In many states, nurses are mandatory reporters of elder mistreatment, which encompasses elder abuse, neglect, and exploitation; Medicare requires that nursing facilities monitor patients for signs of mistreatment. Specific types of elder mistreatment include physical, emotional, verbal, and sexual abuse. They also include neglect and financial abuse. Signs of possible elder abuse include bruises, lacerations, fractures, open wounds, and untreated injuries in various stages of

healing. Dehydration, malnutrition, and poor personal hygiene may signal elder neglect. Agitation, withdrawal, and sudden changes in behavior or financial situation may be indicative of other types of mistreatment (National Center on Elder Abuse [NCEA], n.d.). It is the nurse's responsibility to understand the reporting laws in his or her state and to report mistreatment or suspected mistreatment to the appropriate authorities. Failure to do so may result in civil or criminal penalties (Falk, Baigis, & Kopac, 2012). Even if state law does not identify them as mandatory reporters, it is advisable for nurses to report mistreatment or suspected mistreatment.

Screening and assessment are essential for identifying elder mistreatment. Patient interviews are commonly included in the assessment process, but age-related cognitive impairments can limit their effectiveness. Patients may also be hesitant to disclose mistreatment in an interview for fear that the abuse will worsen if they do so (Falk et al., 2012). Elder mistreatment can be a difficult topic to broach with patients and family members or care providers who may be involved in the mistreatment. In addition, some

signs of elder mistreatment are similar to signs associated with normal age-related changes and conditions. To help nurses better address and identify elder mistreatment, many state and national resources exist. State Boards of Nursing and the National Center on Elder Abuse offer useful information on this topic.

» **Stay Current:** The website of the National Center on Elder Abuse can be found at <https://ncea.acl.gov>.

End-of-life (EOL) care is another important consideration for nurses working with older adults. EOL encompasses both planning and delivery of care. When an advance directive (AD) exists, the nurse is bound to provide care in accordance with the patient's wishes and organizational policy. When no AD exists, patients with capacity to make EOL decisions for themselves may work with the nurse to determine the type of care they prefer (American Cancer Society, 2015). Advance directives are discussed in more detail in Exemplar 49.B. For more on EOL care, see the exemplar on End-of-Life Care in the module on Comfort.

REVIEW The Concept of Legal Issues

RELATE Link the Concepts

Linking the concept of legal issues with the concept of clinical decision making:

1. How does the nursing process support nurses in maintaining appropriate standards of care?
2. What type of consent is necessary for the nurse to take a patient's temperature and vital signs? For the patient to undergo an x-ray if a broken leg is suspected?

Linking the concept of legal issues with the concept of communication:

3. How does a change-of-shift report minimize the nurse's risk for professional negligence or malpractice?
4. What types of communication result in the best quality of patient care and are therefore most likely to prevent the nurse from being accused of malpractice?

REFLECT Apply Your Knowledge

Joanne Otunde, an RN coworker on your surgical unit, returned to work about 6 weeks ago following back surgery. Since her return, you have noticed that she is frequently and uncharacteristically late for work and has called in sick six times. Twice you have witnessed her treating a nurse's aide harshly. Ms. Glancy, a patient who is 2 days postoperative, puts her light on and tells you that she is in severe pain and that the pain medication she received did not have any effect on the pain level. She states, "It's the strangest thing. The pill never seems to work in the evenings the way it does in the daytime and at night." You report Ms. Glancy's pain to Joanne, who is her primary nurse. At the end of the shift, you and an oncoming nurse are doing the narcotic count and notice that Joanne has given six doses of the same narcotic during the shift and one dose is documented as having been given at 8 p.m. to a patient who had been discharged at 5 p.m.

1. What are your responsibilities? Should you take any action? If so, why? If not, why not?
2. What laws do you need to review? What policies?

Anatomy of a Nurse Practice Act

Typically, the following components are addressed in an NPA. Each nursing student and practicing nurse should understand the NPA for the state in which she or he is working and how each component of the NPA affects practice. Components of an NPA include the following:

- Definition of nursing
- Requirements for licensure
- Penalty for practicing without a license
- Exemptions from licensure
- Licensure across jurisdictions.

Overview

The practice of nursing is regulated at the state level through a **nurse practice act (NPA)**. An NPA is a series of state statutes that define the scope of practice, standards for education programs, licensure requirements, and grounds for disciplinary actions. The law provides a framework for establishing nursing actions in the care of patients (**Box 49–3** >>). Laws set the boundaries for and maintain a standard of nursing practice (**Figure 49–3** >>). The nurse is held accountable to the specific standards for licensure and grounds for revocation in the state of employment. For the registered nurse (RN), the provisions of NPAs are quite similar from state to state. Greater variation exists in the scope of practice for the licensed practical nurse (LPN) and licensed vocational nurse (LVN).

Each state's NPA is enforced and administered by a state board of nursing (BON), though some states use other titles for this regulatory board. BONs were established some 100 years ago to standardize the education of nurses, establish standards for safe nursing practice, and issue licenses to protect the public from unprepared, unsafe practitioners. Over the years, BONs have expanded their scope. Programs for impaired nurses, remediation of practice issues, and participation in multistate licensure compacts are all part of BONs today. BONs also act as a forum for citizens to report and discuss concerns regarding nursing services they have

received. In this way, BONs continue to work toward their goal of protecting the public health.

The state's NPA dictates the membership of the state's BON, which usually includes a mix of RNs, LPNs/LVNs, advanced practice registered nurses (APRNs), and consumers. The members of the BON are appointed according to the regulations in each state, with the exception of North Carolina. North Carolina is the only state in which licensed nurses serving on the board are elected by other licensed nurses and members of the public who serve are appointed.

Licensure

Licensure allows a nurse the legal privilege to practice nursing as defined in the state's NPA. Through the process of licensure, the BON ensures the provision of safe nursing care to the public. Typically, BONs oversee licensure through the following activities:

- Establishing and monitoring educational standards for nursing education programs
- Defining professional standards
- Examining and renewing the licenses of duly qualified applicants
- Investigating violations of the NPA
- Sanctioning (to the point of initiating prosecution against) those who violate the NPA
- Holding disciplinary hearings for possible suspension or revocation of a license
- Establishing and overseeing diversity programs in some states. The Focus on Diversity and Culture feature looks at efforts to increase diversity in the nursing workforce.

Focus on Diversity and Culture

Diversity and the Nursing Workforce

Since 2004, the Institute of Medicine (IOM) has emphasized the connection between a diverse nursing workforce and culturally competent nursing care. In particular, the IOM posits that diversity among nurses will improve access to care for minority patients and will result in greater patient satisfaction (American Association of Colleges of Nursing [AACN], 2016).

A diverse workforce begins by increasing the number of minority students enrolled in nursing programs. The AACN reports that the number of minority students in nursing programs has steadily increased since 2011, with nearly 30% of students at all levels representing minority populations. The number of male students in nursing programs has also increased; as of 2015, roughly 12% of nursing students were male (AACN, 2016).

Federal government involvement has been an important factor in these increases. Through the Nursing Workforce Diversity (NWD) program, the Health Resources and Services Administration (HRSA) is striving to increase educational opportunities for groups that are underrepresented in the registered nurse population (HRSA, 2014b). The program provides grants to schools of nursing that are committed to increasing the number of minority graduates. Recipient organizations can use funds for scholarships, stipends, and advanced education preparation. Between \$14 million and \$16 million in grants have been awarded through this program each year since 2006 (AACN, 2016).

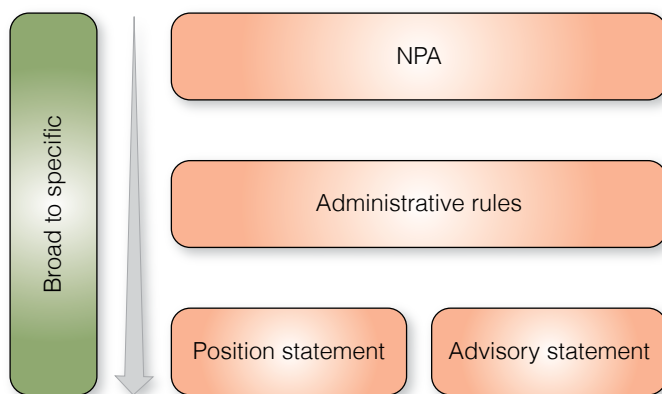

Figure 49–3 >> Relationship among nurse practice acts, administrative rules, and position/advisory statements.

Each BON oversees the administration of a licensure examination that measures the competencies needed to perform safely and effectively as a newly licensed, entry-level nurse. The National Council of State Boards of Nursing (NCSBN) has developed two licensure examinations, the National Council Licensure Examination for Registered Nurses (NCLEX-RN®) and the National Council Licensure Examination for Practical Nurses (NCLEX-PN®), for state and territory BONs to implement as part of their requirements for licensure. The NCSBN also offers two additional examinations: the National Nurse Aide Assessment Program and the Medication Aide Certification Examination (NCSBN, 2016a).

Licenses are issued by the state or territory in which the applicant nurse wishes to practice. For licensed nurses at all levels of practice, the BON monitors compliance with state laws, including maintaining continued competency and annual renewal of licensure. To maintain the privilege to practice afforded by the license, the individual nurse is required to demonstrate awareness and application of standards of nursing care and meet his or her responsibilities to both patients and the healthcare system. The board is also responsible for taking action against nurses who have exhibited unsafe nursing practice or otherwise engaged in professional misconduct or who fail to meet requirements for licensure renewal.

Each BON details what charges of professional misconduct may result in the revocation or suspension of a nurse's license. Most BONs will take action against the nurse who is found guilty of charges that include the following:

- Giving false information or withholding material information from the board in procuring or attempting to procure a license to practice nursing.
- Being convicted of or pleading either guilty or *nolo contendere* to any crime that indicates the nurse is unfit or incompetent to practice or has deceived or defrauded the public. In pleading **nolo contendere**, the individual neither admits nor denies that he or she has committed the crime but agrees to a punishment (usually a fine or jail time) as if guilty. Usually, this type of plea is entered because it can-

not be used as an admission of guilt if a civil lawsuit is initiated following the conclusion of a criminal trial.

- Engaging in conduct that endangers the public health.
- Being unfit or incompetent to practice by reason of deliberate or negligent acts or omissions, regardless of whether actual injury to the patient is established.
- Engaging in conduct that deceives, defrauds, or harms the public in the course of professional activities or services.

National Council of State Boards of Nursing

The NCSBN provides leadership to advance regulatory excellence for public protection. The membership of the NCSBN includes BONs in the 50 states, the District of Columbia, and four U.S. territories (Guam, Virgin Islands, American Samoa, and the Northern Mariana Islands). Four states (California, Georgia, Louisiana, and West Virginia) have separate BONs for RNs and LPNs/LVNs.

The NCSBN offers a number of services that support member BONs. It is responsible for developing the licensure and assessment exams mentioned earlier. In addition, the NCSBN offers continuing education opportunities via its e-learning community.

The NCSBN also serves as an important source of data and research about nursing practice (**Box 49-4** >>>). It maintains a central nursing database called Nursys that coordinates nurse licensure information for the United States. It also works with BONs to promote uniform regulation of nursing practice. The Nurse Licensure Compact is an important outcome of these activities.

>> **Stay Current:** Contact information for state Boards of Nursing and information about licensure and NCSBN research can be found at <https://www.ncsbn.org/boards.htm>.

Nurse Licensure Compact

The **mutual recognition model** of nurse licensure allows a nurse to have a single license that confers the privilege to practice in other states that are part of the Nurse Licensure

Box 49-4

NCSBN Research in 2015

National Nursing Workforce Survey

- Collected demographic and other information related to the supply of RNs and LPNs/VNs in the United States.
- Explored trends in the nursing workforce and compared them to trends in past years' surveys.
- Examined the impact that telehealth is having on nursing practice.

National Simulation Study

- Explored the role and outcomes of simulation training in nursing education.
- Used a three-phase approach to study the current use of simulation, to examine the impact of simulation in place of traditional

clinical hours, and to follow clinical practice of nursing graduates trained using simulation.

- Identified simulation as an important preparatory tool for student nurses.

Transition to Practice

- Explored the issues that lead to high attrition rates and stress in new nurses.
- Worked with a variety of nursing organizations to develop a standardized model to aid in retention of new nurses and to improve outcomes for patients cared for by these nurses.
- Designed e-learning modules to supplement the newly developed model.

Box 49–5

Mutual Recognition Model

- Each state has to enter into an interstate compact, called the Nurse Licensure Compact (NLC), that allows nurses to practice in more than one state.
- Multistate licensure privilege means the nurse has the authority to practice nursing in another state that has signed an interstate compact. It is not an additional license.
- A nurse must have a license in his or her primary state of legal residency if that state is an NLC state.
- The states continue to have authority in determining licensure requirements and disciplinary actions.
- The nurse is held accountable for knowing and practicing the nursing practice laws and regulations in the state where the patient is located.
- Enactment does not change a state's nurse practice act.
- Complaints and/or violations are addressed by the home state (place of residence) and the remote state (place of practice).
- RNs and LPNs/LVNs are included in the interstate compact or NLC. Since 2002, there has been a separate APRN Compact. A state must be a member of the NLC for RNs and LPNs before entering into an APRN Compact. A state must adopt both compacts to cover LPNs/RNs and APRNs for mutual recognition.

Source: National Council of State Boards of Nursing (NCSBN). (2016b). *Nurse licensure compact: Information for new grads*. Retrieved from https://www.ncsbn.org/NLC_New_Grads.pdf.

Compact (**Box 49–5** >>). Monitoring the nurse's license and taking any needed disciplinary actions are the responsibilities of the state that issues the license. It is similar to the driver's license model: A single license to drive is issued in the individual's state of primary residency, but this license also gives the individual the privilege to drive in other Drivers' License Compact states.

SAFETY ALERT When practicing in a mutual recognition state, the nurse is held accountable for following the laws and rules of the state in which he or she is practicing or where the patient is located, not the state that issued the license.

To achieve mutual recognition, each state must enact legislation or regulations authorizing the Nurse Licensure Compact. States that enter the compact also adopt administrative rules and regulations for implementation of the compact. Twenty-five states are currently part of the compact.

>> **Stay Current:** For information on states participating in the compact, go to <https://www.ncsbn.org/nurse-licensure-compact.htm>.

Credentialing

Although a nursing license grants the legal privilege to practice, **credentialing** is the formal identification of professionals who meet predetermined standards of professional skill or competence. The federal government has used the term **certification** to define the credentialing process by which a nongovernmental agency or association recognizes the professional competence of an individual who has met certain predetermined qualifications specified by the agency or

association. The American Nurses Credentialing Center (ANCC), a subsidiary of the ANA, provides credentialing programs to certify nurses in specialty practice areas, recognizes healthcare organizations for nursing excellence through the Magnet Recognition Program, and accredits providers of continuing nursing education and nursing specialty organizations.

Federal organizations, such as The Joint Commission and the Centers for Medicare and Medicaid Services, and federal guidelines affect the standards of care the nurse is held accountable for practicing. Individual healthcare agencies must implement policies, procedures, and job descriptions to ensure that the nurses they employ follow all applicable regulations and guidelines. The nurse needs to know the employing institution's policies and procedures and the specific job descriptions of the licensed and unlicensed nursing personnel. The purpose of knowing the standards of care is to protect both the patient and the nurse.

The impact of laws and standards on nurses is profound (**Figure 49–4** >>). The professional nurse is held accountable for many standards and statutes. Knowledge of the laws that regulate and affect nursing practice enables the nurse to practice within current legal principles and be aware of his or her legal obligations and responsibilities.

Nursing Students

Each NPA addresses the duties and responsibilities of nursing students in that state. Typically, this includes language that allows nursing students the privilege to practice nursing without a license while engaged in the clinical practicum of an approved nursing education program under the supervision of qualified faculty. Nursing students have the ultimate **responsibility** (accountability for their actions that includes the obligation to answer for an act done and to repair any injury one may have caused) for their own actions. Guidelines for clinical performance for nursing students include the following (Virginia Board of Nursing, 2012):

1. Provide safe nursing care.
2. Understand program and facility policies and procedures before undertaking any clinical assignment.
3. Demonstrate knowledge about the patient's condition, interventions, medications, and treatments.

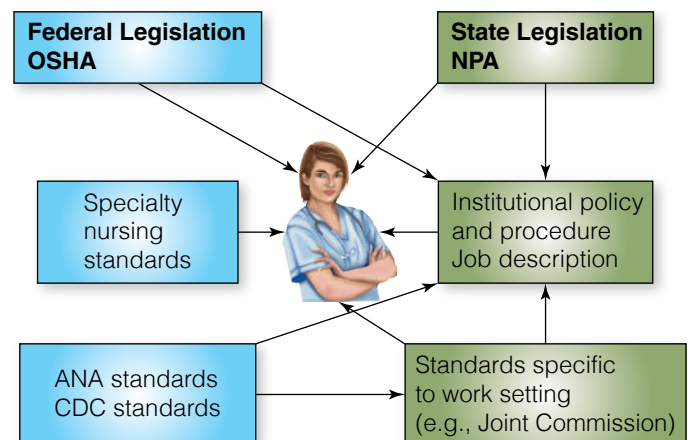

Figure 49–4 >> Impact of laws and standards on nurses.

4. Perform care only to the highest level of nursing knowledge; if you are unprepared for a clinical assignment, inform your instructor.
5. Seek help before beginning a procedure about which you are unsure; if the instructor is not readily available, allow the staff nurse to perform the intervention.

Nursing students are held accountable to the same standard of care as licensed nurses. Nursing faculty members are held accountable for appropriate assignment and supervision of students.

SAFETY ALERT Student nurses do not practice on a faculty member's license. The only individual who can legally practice on a license is the individual whose name appears on the license.

Standards of Practice

Nursing, as a profession, has a responsibility to self-regulate by defining the practice of nursing, researching and developing the practice, establishing standards of practice, and providing for the education and credentialing of nurses. The ANA, the largest professional nursing organization, has established Standards of Clinical Nursing Practice. These address both standards for nursing care and standards for professional performance. Standards of practice are also available for various nursing specialties, including pediatric nursing, nurse anesthesia practice, critical care nursing, and psychiatric nursing.

REVIEW Nurse Practice Acts

RELATE Link the Concepts and Exemplars

Linking the exemplar of nurse practice acts with the concept of addiction:

1. What resources does your state's board of nursing offer for nurses who are struggling with substance abuse?
2. What would you do if you realized that a nurse you were working with was under the influence of drugs or alcohol? Explain.

Linking the exemplar of nurse practice acts with the concept of accountability:

3. What does your state's Nurse Practice Act say about the accountability of nursing students? How is that different from what the NPA says about the accountability of registered nurses?
4. How does your state's board of nursing support or assist nurses in their professional development?

REFLECT Apply Your Knowledge

Sarah Coulton is a registered nurse who works with you in a primary care clinic. Her husband has been notified that his employer is transferring him to another state, and Sarah and her family will be moving in a couple of months.

1. Where will Sarah be able to find information on which states have mutual recognition with your state?
2. What steps might Sarah need to take if she learns that she is moving to a state that is not part of the Nurse Licensure Compact?

Exemplar 49.B Advance Directives

Exemplar Learning Outcomes

49.B Analyze advance directives as they relate to legal issues.

- Describe types of healthcare advance directives.
- Outline elements of advance directives.
- Explain the role of the nurse in assisting families with advance directives.

Overview

A **healthcare advance directive** (sometimes referred to as an AD) is a legal document executed by an individual that expresses that individual's desires regarding medical treatment that may be used if and when the individual is no longer able to communicate his or her preferences directly (Ryan & Jezewski, 2012). The patient's right to use ADs is guaranteed in the Patient Self-Determination Act. The **Patient Self-Determination Act** is a federal law requiring

Exemplar Key Terms

Durable power of attorney for healthcare, 2843

Healthcare advance directive, 2842

Living will, 2843

Patient Self-Determination Act, 2842

healthcare institutions that receive federal funding (but not individual healthcare providers) to do the following:

1. At the time of admission, give patients a written summary of:
 - Healthcare decision-making rights. (Each state has developed such a summary for hospitals, nursing homes, and home health agencies to use.)
 - The facility's policies with respect to recognizing ADs.

Focus on Diversity and Culture

Advance Directives

A majority of Americans feel that individuals have the right to direct what sort of medical treatment they receive at the end of life. Despite this widespread belief, fewer than one third of Americans have established ADs—and this percentage is even lower among people of color. As a result, members of minority groups are significantly less likely than White Americans to have their final wishes followed (Benson & Aldrich, 2012; Minority Nurse, 2013).

There are multiple reasons why people of color are less likely to have ADs than their White counterparts. For example, individuals who do not understand English and those who are non-native speakers may find it difficult, if not impossible, to understand AD forms and/or the terminology used by healthcare workers when discussing ADs. Still other individuals might not create ADs because of cultural beliefs, mistrust of the healthcare system, or inaccurate perceptions of how ADs actually work. Some Chinese patients, for instance, tend to view death as a taboo subject, and they may believe that planning for EOL care will doom them to dying in the near future. Similarly, some African American patients may view ADs as a sign that they've given up on God or abandoned hope for recovery. Some African Americans further believe that ADs are unnecessary because their family will make the right decisions for them, or they fear that they won't actually receive the care described in their ADs because of past instances of institutional racism in healthcare. In comparison, Latino patients may lack ADs because they are unfamiliar with the concept. Some members of Latino populations may also believe that hospice care is the same thing as nursing home

care and thus violates their traditional cultural belief that sick and dying individuals be cared for in the home by family members (Minority Nurse, 2013). Yet other possible explanations for differences in AD use among minority groups include lower health literacy levels, physician bias, and reduced access to care (Fischer et al., 2012).

Nurses are in an ideal position to help people of color better understand the value of ADs and establish these documents as needed. One key step is to encourage patients to discuss EOL issues with their loved ones; here, the nurse should emphasize the importance of the discussion itself rather than the need to obtain a signed AD. To foster such discussions, nurses should approach the topic in a manner that is appropriate to each patient's cultural, religious, and personal preferences. This requires that nurses be knowledgeable about other cultures and try to consider the situation from their patients' point of view. It is often useful to frame ADs as positive devices that clarify what care measures an individual wants, rather than what measures he or she wishes to avoid. Patients may also find reassurance in the idea that ADs relieve their loved ones of the burden of making life-or-death decisions on their behalf. Nurses should be sure to explain any unclear or culturally sensitive terminology used in AD documents. In addition, nurses can further promote AD adoption by encouraging their employers and other healthcare organizations to use EOL planning documents that are simple to read and understand, as well as culturally and linguistically appropriate to various communities (Minority Nurse, 2013).

2. Ask patients whether they have an AD and document the AD's existence in the medical record. (It is up to the patient to provide a copy of the AD.)
3. Educate staff and community about ADs.
4. Ensure that the individuals know that the facility never discriminates on the basis of whether or not the individual has an AD.

Competent patients may execute ADs at any time. ADs are formal, written documents that typically outline the patient's desires regarding the following:

- Use or withholding of hydration and/or total parenteral nutrition
- Resuscitation or intubation in the event of a life-threatening emergency (Do-not-resuscitate and do-not-intubate orders are discussed in the exemplar on End-of-Life Care in the module on Comfort)
- The individual with the authority to make decisions on the patient's behalf in the event the patient is unable to do so (referred to as a healthcare surrogate)

Types of ADs include the living will and the durable power of attorney for healthcare. A **living will** provides specific instructions about what medical treatment the patient chooses to omit or refuse (e.g., ventilator support) in the event that the patient is unable to make such a decision. Through a **durable power of attorney for healthcare**, the patient may designate another individual (usually a family member, significant other, or close personal friend) as *healthcare surrogate* or *healthcare proxy*

and give that individual power to make healthcare decisions on behalf of the patient if the patient is unable to do so. These may be combined into a single document or may be two separate documents. The Focus on Diversity and Culture feature looks at the use of ADs by various populations.

» **Stay Current:** Information about advance directives can be found at the Health in Aging Organization website at <https://www.nia.nih.gov/health/publication/end-life-helping-comfort-and-care/planning-end-life-care-decisions>.

Clinical Example B

Gary Casper, a 65-year-old man, has been in the hospital several times in the past year with a deteriorating diagnosis. After Shondra Lewis, the patient's RN, completes her assessment of Mr. Casper's current condition and his concerns, she contacts the case management department for assistance with his concerns regarding his end-of-life care choices. Ms. Lewis tells the case manager that the patient's wife will not allow him to prepare an AD, which Mr. Casper wants to do, since he decided to be DNR on this current admission. The next day, the social worker meets with Mr. Casper separately from his wife to discuss his right for self-determination and how to prepare an AD form. Mr. Casper is relieved that he can complete the form in the hospital, but he is concerned that his wife will still be able to prevent this, as he does not want her to have a power of attorney for him. Plans are put in process for Mr. Casper to complete the advance directive with appropriate staff and another family member while the physician speaks with Mrs. Casper in a conference room.

Critical Thinking Questions

1. How did the staff support this patient's right to self-determination?
2. Did the physician violate the wife's right to be with her spouse in this case? Explain.
3. How can nursing staff further assist Mr. Casper in facing end-of-life care choices?
4. How can the staff support Mrs. Casper as she faces the end of her husband's life?

Elements of an Advance Directive

A broadly drafted AD usually gives an agent or surrogate decision maker authority to do the following:

- Consent to or refuse any medical treatment or diagnostic procedure relating to the individual's physical or mental health, including artificial nutrition and hydration.
- Hire or discharge medical providers, and authorize admission to medical and long-term care facilities.
- Consent to measures for comfort care and pain relief.
- Have access to all medical records.
- Take whatever measures are necessary to carry out wishes, including granting releases or waivers to medical facilities and seeking judicial remedies if problems arise.

Each state, through legislation, determines the specific requirements for healthcare ADs. In most states, ADs must be witnessed by two people and do not require review by an attorney. Many states require that a specific legislated form be used. The majority of states do not permit relatives, heirs, or primary care providers to serve as witnesses for ADs (Ryan & Jezewski, 2012). In some states, the patient has the option to limit the authority of the healthcare agent as desired. Nurses working with a patient who has an AD should ensure that they understand what the patient's AD includes and should know the laws in the state related to self-determination as well as the employing agency's policies and procedures for following ADs.

Figure 49-5 » shows an example of a healthcare AD that combines a living will declaration and a durable power of attorney for healthcare.

» **Stay Current:** Samples of state-specific forms can be obtained from the National Hospice and Palliative Care Organization at www.nhpco.org.

One popular AD is Five Wishes. This form was developed to simplify the process of drafting an AD and is specifically designed to address not only the healthcare aspects of EOL, but the emotional and spiritual issues as well (Aging with Dignity, 2015). The form addresses five areas:

1. The person who will make care decisions when the patient cannot
2. The kinds of medical treatment the patient does and does not want
3. The level of comfort the patient would prefer
4. The way the patient would prefer to be treated by others

5. The information the patient would like his or her loved ones to know.

Specific concerns in each of these areas is addressed via questions on the form. Patients circle or cross out answers or write one- or two-sentence responses to these questions (Aging with Dignity, 2015). Questions and responses are written in simple language that is easy for laypeople to understand.

Five Wishes is widely used, and 42 states currently accept the form as an AD. Patients 18 and older may use the form. It is available in 27 languages (Aging with Dignity, 2015). Five Wishes does not meet the technical requirements for an AD in Alabama, Indiana, Kansas, New Hampshire, Ohio, Oregon, Texas, and Utah. Patients living in these states who wish to use the Five Wishes AD must append it to the government-approved AD form required by their state.

Role of the Nurse

Patients and families often have difficulty making advance treatment decisions for EOL matters. The nurse should reassure them that if they make a decision and have an AD, they will have the option to change their decision. For example, the patient may have decided not to have ventilator support in the case of terminal illness, but when the situation occurs, the patient has the right to change his or her mind or take more time to make the decision.

SAFETY ALERT Nurses can assist patients and their families by instructing patients to provide a copy of their advance directives to their next of kin, primary healthcare providers, and any healthcare facility to which they are admitted, including emergency departments, rehabilitation facilities, and senior living centers.

The nurse needs to assess whether the patient and family have an accurate understanding of life-sustaining measures. Patients and families may misunderstand what actions may sustain life and base their decisions on these misconceptions. The nurse needs to incorporate teaching in this area and continue to be supportive of patients' decisions. The Evidence-Based Practice feature looks at additional aspects that may affect a patient's likelihood to have an AD.

For patients without an AD who no longer have capacity to make decisions, a surrogate may be selected. Nurses may be involved in assessing a patient's capacity, but selection of a surrogate is typically dictated by the state. Generally, the spouse is the first choice as surrogate, followed by an adult child, a parent, and an adult sibling. Decision making by the surrogate is generally governed by one of two criteria. The first is the substituted judgment standard. With this standard, the surrogate infers the choice the patient would make on the basis of past conversations with the patient or knowledge of the patient's beliefs and values. The second is the best interest standard. With this standard, the surrogate weighs the benefits and risks of treatment options and selects the one that he or she believes will be most beneficial for the patient.

POWER OF ATTORNEY FOR HEALTH CARE

(1) **DESIGNATION OF AGENT:** I designate the following individual as my agent to make health care decisions for me: _____

(Name of individual you choose as agent)

(address) (city) (state) (zip code)

(home phone) (work phone)

OPTIONAL: If I revoke my agent's authority or if my agent is not willing, able, or reasonably available to make a health-care decision for me, I designate as my first alternate agent:

(Name of individual you choose as first alternate agent)

(address) (city) (state) (zip code)

(home phone) (work phone)

OPTIONAL: If I revoke the authority of my agent and first alternate agent or if neither is willing, able, or reasonably available to make a health care decision for me, I designate as my second alternate agent:

(Name of individual you choose as second alternate agent)

(address) (city) (state) (zip code)

(home phone) (work phone)

(2) **AGENT'S AUTHORITY:** My agent is authorized to make all health care decisions for me, including decisions to provide, withhold, or withdraw artificial nutrition and hydration, and all other forms of health care to keep me alive, **except** as I state here:

(3) **WHEN AGENT'S AUTHORITY BECOMES EFFECTIVE:** My agent's authority becomes effective when my primary physician determines that I am unable to make my own health care decisions unless I mark the following box. If I mark this box ☐, my agent's authority to make health care decisions for me takes effect immediately.

(4) **AGENT'S OBLIGATION:** My agent shall make health care decisions for me in accordance with this power of attorney for health care, any instructions I give below, and my other wishes to the extent known to my agent. To the extent my wishes are unknown, my agent shall make health care decisions for me in accordance with what my agent determines to be in my best interest. In determining my best interest, my agent shall consider my personal values to the extent known to my agent.

(5) **AGENT'S POSTDEATH AUTHORITY:** My agent is authorized to make anatomical gifts, authorize an autopsy, and direct disposition of my remains, except as I state here or elsewhere in this form:

INSTRUCTIONS FOR HEALTH CARE

Strike any wording you do not want.

(6) **END-OF-LIFE DECISIONS:** I direct that my health care providers and others involved in my care provide, withhold, or withdraw treatment in accordance with the choice I have marked below: **(Initial only one box)**

☐ (a) **Choice NOT To Prolong Life**

I do not want my life to be prolonged if (1) I have an incurable and irreversible condition that will result in my death within a relatively short time, (2) I become unconscious and, to a reasonable degree of medical certainty, I will not regain consciousness, or (3) the likely risks and burdens of treatment would outweigh the expected benefits, **OR**

☐ (b) **Choice To Prolong Life**

I want my life to be prolonged as long as possible within the limits of generally accepted health care standards.

(7) **RELIEF FROM PAIN:** Except as I state in the following space, I direct that treatment for alleviation of pain or discomfort should be provided at all times even if it hastens my death:

DONATION OF ORGANS AT DEATH

(8) Upon my death: (mark applicable box)

☐ (a) I give any needed organs, tissues, or parts,

OR

☐ (b) I give the following organs, tissues, or parts only: _____

☐ (c) My gift is for the following purposes:

(strike any of the following you do not want)

(1) Transplant

(2) Therapy

(3) Research

(4) Education

(9) **EFFECT OF COPY:** A copy of this form has the same effect as the original.

(10) **SIGNATURE:** Sign and date the form here:

(date) (sign your name)

(address) (print your name)

(city) (state)

(11) **WITNESSES:** This advance health care directive will not be valid for making health care decisions unless it is either: (1) signed by two (2) qualified adult witnesses who are personally known to you and who are present when you sign or acknowledge your signature; or (2) acknowledged before a notary public.

Figure 49-5 » Sample advance healthcare directive.

Evidence-Based Practice

End-of-Life Care for Patients with Terminal Cancer

Problem

When working with patients diagnosed with terminal cancer, nurses must be prepared to discuss advance directives (ADs). If an AD does not exist, the nurse needs to understand the complex psychosocial and emotional issues the patient is experiencing and incorporate these into a compassionate, professional conversation about end-of-life (EOL) care. When doing so, the nurse should understand that patient wishes related to EOL are tied to a number of complex influences.

Evidence

Miljoković et al. (2015) surveyed adults with cancer about the existence of and attitudes toward do not resuscitate (DNR) and allow natural death (AND) orders. The researchers discovered that, although the patients surveyed were identified as terminal by their physicians, only 42% considered themselves terminally ill. In addition, only 50% of patients had a DNR or AND order in place. Patients were increasingly likely to create DNR or AND orders as their prognosis worsened and their survival time shortened. In addition, the researchers hypothesized that the concept of an AND order might be more acceptable than a DNR order for emotional reasons, but patients did not exhibit a statistically significant preference for one type of order over the other.

Crosby et al. (2016) explored the link between gender and DNR orders in patients with cancer. The researchers discovered that female patients were 1.3 times more likely to have DNR orders early in their illness than male patients. They also discovered that female physicians were 1.5 times more likely to write early DNR orders for their female patients than for their male patients. The researchers did not find a similar correlation in male patient–male physician pairs. Age at time of diagnosis, comorbid conditions, and disease progression were also found to be factors in the timing of DNR order creation.

Ahmed and colleagues (2015) looked specifically at DNR orders in patients with lung cancer. Their research revealed that, while patients at all disease stages typically received family support for creating DNR orders, patients' uncertainty about the extent of their

disease and amount of time remaining were key factors in DNR order preparation. Most patients indicated that, even if they did not have a DNR order in place, they had considered the need for one; many had also sought advice about DNR orders from their physicians. A primary area of concern for patients without DNR orders was linked to hope; many patients felt that creating a DNR order was akin to giving up hope for long-term survival. Others indicated concern about the reversibility of DNR orders and the quality of care they would receive if healthcare providers knew they had a DNR in place.

Implications

Patients diagnosed with terminal cancer have differing views on ADs, and individual patient opinions related to ADs may be affected by prognosis, time remaining, gender, and feelings of hope. It is essential that the nurse not make assumptions about whether a patient has an AD; it is equally important that the nurse use tact and understanding when addressing this complex issue with a patient. In addition, the nurse should ensure that the patient understands the legal aspects of DNR orders, including the reversibility of orders and the process that must be undertaken to change a DNR order. The nurse should also make clear the healthcare providers' legal obligation to provide high-quality care even in the presence of a DNR order.

Critical Thinking Application

1. Why might a patient's perception of the terminal nature of a cancer diagnosis affect the patient's likelihood of having a DNR or AND order?
2. What reasons might explain the higher likelihood of female patients with cancer to have DNR orders earlier than male patients? Why is the female patient–female physician information important to consider?
3. Why is family support for creation of a DNR order important in working with a terminally ill patient with cancer? How can the nurse leverage this support?

REVIEW Advance Directives

RELATE Link the Concepts and Exemplars

Linking the exemplar of advance directives with the concept of cognition:

1. Why might it be advisable to discuss development of ADs with a patient who is in the early stages of Alzheimer disease?
2. How might a patient with schizophrenia benefit from an AD that includes instructions related to psychiatric care and treatment?

Linking the exemplar of advance directives with the concept of communication:

3. What communication strategies would you use to address the need to develop ADs with a patient? With the patient's family members?
4. What communication strategies would you use to help a family member understand that his mother is no longer able to make her own decisions and it is time to review and follow the ADs that she put in place?

REFLECT Apply Your Knowledge

Heather King is a 53-year-old woman who is hospitalized with a newly diagnosed malignant brain tumor. She has signed an AD that indicates she does not want any extraordinary measures to keep her alive if she has an incurable or irreversible condition that will result in her death within a relatively short period of time. The neurosurgeon has presented her with treatment options. Ms. King refuses treatment for the tumor, requesting only palliative care "until the time comes." Her husband speaks to the neurosurgeon outside of Ms. King's room, stating, "I want everything possible done! The children and I have discussed this, and we don't agree with not treating the tumor."

1. What should happen with Ms. King's treatment? Why?
2. How may the family's reaction affect implementation of the AD?
3. In what circumstances could the patient's family member refuse or consent to treatment for the patient?
4. What law, rule, or policy describes the nurse's responsibility?

Exemplar 49.C

Health Insurance Portability and Accountability Act

Exemplar Learning Outcomes

49.C Analyze the Health Insurance Portability and Accountability Act (HIPAA) as it relates to legal issues.

- Explain the purpose of HIPAA.
- Explain how the Privacy Rule covers protected health information.
- Differentiate privacy and confidentiality.

Overview

The **Health Insurance Portability and Accountability Act (HIPAA)** of 1996 was enacted by Congress to minimize the exclusion of preexisting conditions as a barrier to healthcare insurance, designate special rights for individuals who lose other health coverage, and eliminate medical underwriting in group plans. The act includes the Privacy Rule, which creates a national standard for the disclosure of private health information. This rule affects all healthcare providers as well as health insurance plan providers (McGowan, 2012).

Protected Health Information

The Privacy Rule protects all “individually identifiable health information” held or transmitted in any form or medium, whether electronic, paper, or oral. The rule calls this information **protected health information** and delineates it further to include information that identifies the individual (e.g., name, address, birth date, and Social Security number) or for which a reasonable basis exists to believe the information can be used to identify the individual as it relates to the following:

- The individual’s past, present, or future physical or mental health or condition
- The provision of healthcare to the individual
- The past, present, or future payment for the provision of healthcare to the individual.

HIPAA also includes provisions for the protection of patients that address access to medical records, requires notice of privacy practices and opportunity for confidential communications, limits on use of medical information beyond the sharing among healthcare providers directly involved in providing care, and prohibition of the use of personal information for marketing.

In the event that a patient feels a healthcare plan or provider has violated his or her rights according to HIPAA, the individual may file a formal complaint either directly to the entity that committed the violation or to the office for Civil Rights of the U.S. Department of Health and Human Services. Information about how to file a complaint should be included in each entity’s notice of privacy practices. Willful violation of the Privacy Rule can result in civil or criminal penalties for the individuals involved. In most cases, violations that are corrected within 30 days are

Exemplar Key Terms

Health Insurance Portability and Accountability Act (HIPAA), 2847

Privacy, 2848

Protected health information, 2847

not subject to civil penalties (American Medical Association [AMA], 2016).

Nurses must maintain an understanding of current law in order to protect the patient’s privacy and to avoid civil punitive damage suits and possible criminal charges. Nurses should be familiar with the particular policies of their employers.

Clinical Example C

D’Alice Jones and Otis Harvey are RNs in the oncology unit at Mercy Hospital. They are standing behind the nurse’s station having a whispered conversation about Sandy Wagner, a 60-year-old female patient with terminal cancer.

“She didn’t do well with today’s treatment. She’s been vomiting at least twice an hour for the last three hours,” D’Alice says.

“Poor Mrs. Wagner. I wish there was more we could do to make her feel better. But she’s refused all pain and antinausea medication,” Otis replies.

“I know. She told me today that she’s about ready to give up on treatments and just let whatever happens happen,” D’Alice responds.

Just then, D’Alice and Otis notice Mrs. Wagner’s son standing a few feet from the nurses’ station with a horrified look on his face. When he sees them looking at him, he quickly turns and walks away.

Critical Thinking Questions

1. Assuming that the patient’s son overheard their conversation, are the two nurses in violation of the Privacy Rule? Why or why not?
2. What additional precautions could the nurses have taken to avoid their conversation being overheard?

In spite of the extensive efforts of the healthcare industry, the general population remains confused about their actual rights, and some healthcare workers remain unclear about what is and is not allowed under HIPAA (Bova, Drexler, & Sullivan-Bolyai, 2012; McGowan, 2012). Ultimately, maintaining the security of protected health information provides for the protection of the most vulnerable populations, and personnel in covered entities will need to continue to learn and implement the HIPAA standards.

SAFETY ALERT Disclosure of patient information is a breach of confidentiality that may subject a nurse to legal action. Disclosure of confidential information occurs when a patient’s condition—for example, a diagnosis of HIV infection—is discussed inappropriately with any third party. In addition, privacy must be provided when calling individuals in for office visits and in all provision of care.

Privacy Versus Confidentiality

Privacy includes the right of individuals to keep their personal information from being disclosed. The individual decides when, where, and with whom to share his or her health information. **Confidentiality** refers to the assurance the patient has that private information will not be disclosed without his or her consent. Confidentiality applies both to the nature of the information the nurse obtains from the patient and to how the nurse treats patient information once it has been disclosed to the nurse (ANA, 2015):

- **Obtaining information.** Nurses should request and record only information pertinent to the health status of patients to whom they are assigned. If the nurse runs into a neighbor in the emergency department waiting room, for example, it would be inappropriate for the nurse to ask the neighbor, “What are you doing here?” This would inadvertently invite protected information that this nurse does not need for provision of healthcare.
- **Disclosing information.** Information obtained from the patient should be disclosed only to individuals who are directly involved in providing that patient’s healthcare. Even the presence of the individual in the healthcare setting is protected information. It would be a breach of confidentiality, for example, for the nurse to go home and tell her family that a state senator or representative, the family’s pastor, a neighbor, or anyone else was a patient. Protection of patient information, once disclosed, is one tenet of the nurse’s responsibility as the patient’s advocate, and challenges to patient privacy can include other members of the interprofessional team.
- **Advocating for confidentiality.** Nurses are professionally obligated not only to avoid participating in discussions of patients outside communications directly related to providing care but also to curb others from participation. Gossiping at work is common in many organizations, but it has no place in the healthcare setting. Celebrity status, notoriety, and an unusual medical

condition all add to the potential risks to confidentiality. If the nurse is in a coffee shop and hears another nurse or healthcare provider discussing a patient, the nurse is expected to redirect those professionals to maintain patient privacy.

In addition to the actions and behaviors described here, nurses should be familiar with the specific policies and procedures for protecting patient privacy and confidentiality for the healthcare agency in which they work.

Disclosure

A patient’s protected health information can be disclosed under certain conditions without express permission from the patient. These disclosures include providing information to the patient, to other providers who are treating the patient, and to individuals involved in payment processing and other healthcare operations. Information must also be disclosed where required by law or court order, where necessary to protect public health, and when abuse or neglect are suspected. When such disclosure occurs, information should be limited to the minimum necessary for the situation. Providing information beyond what is required is a breach of the Privacy Rule. Informal patient permission may be sufficient for providing information to the patient’s family, friends, or other individuals identified by the patient (McGowan, 2012). In general, when circumstances give the patient the opportunity to agree or object, the nurse should ask for the patient’s permission to disclose information.

Incidental disclosure of patient information may occur in some circumstances. For example, conversations with patients or colleagues about patient care may be overheard by others. The Privacy Rule permits some incidental disclosure of this sort, provided that appropriate safeguards are in place. In this case, reasonable safeguards would include holding such conversations in private locations if possible; if this is not possible, the nurse should try to speak quietly (McGowan, 2012).

REVIEW Health Insurance Portability and Accountability Act

RELATE Link the Concepts and Exemplars

Linking the exemplar of Health Insurance Portability and Accountability Act with the concept of trauma:

1. When and how is it appropriate to break the confidentiality of patients who threaten harm to themselves or others?
2. What additional considerations are involved when it comes to protecting the confidentiality of victims of domestic violence? Of child abuse?

Linking the exemplar of Health Insurance Portability and Accountability Act with the concept of reproduction:

You are the nurse at a local high school. A 16-year-old student has been in the bathroom off and on all morning. She is very nauseated but has been adamant about staying at school. You sit down to talk with her and learn that she thinks she is pregnant. She says, “I don’t know what to do. I don’t want my parents to know.”

3. What are your responsibilities to this patient regarding her privacy and confidentiality?
4. What are the laws in your state that relate to the ability of minors to make independent decisions regarding their own pregnancies?

REFLECT Apply Your Knowledge

Michael Nguyen is a nurse on the medical–surgical unit of a busy suburban hospital. Approximately 20 minutes ago, the nursing unit was notified that seven patients who were involved in a motor vehicle crash and are receiving treatment in the emergency department (ED) are expected to be admitted to the med–surg unit in varying conditions. Carole Fulton, another nurse working on the unit, has been liaising with the ED staff about the situation. Michael

goes to answer a patient call bell. When he returns to the nursing desk, he overhears Carole on her cell phone saying, “Yes, that accident on Highway 40. Yeah, apparently it’s really bad. I saw Reverend Mitchell downstairs. Yeah. No. His daughter was a passenger. OK. Bye.” Carole hangs up the phone and puts it in her purse, saying, “My mom. She called to tell me she got home safely from work.” Thirty minutes later, Michael receives a report on a

patient named Elizabeth Mitchell who is being transported up from the ED.

1. What concerns might Michael have about the content of Carole’s phone call with her mother? How might Carole have violated Ms. Mitchell’s privacy or confidentiality?
2. If you had been Michael, what responsibility would you have to address your concerns?

Exemplar 49.D Mandatory Reporting

Exemplar Learning Outcomes

49.D Analyze mandatory reporting as it relates to legal issues.

- Describe the legalities of mandatory reporting.
- Outline situations that require mandatory reporting.
- Differentiate considerations related to mandatory reporting across the lifespan.

Overview

The term **mandatory reporting** refers to the legal requirement to report an act, event, or situation that is designated by state or local law as a reportable event (Katner, 2012). Disclosure statutes mandate the reporting of certain types of health information, and all states mandate the reporting of certain vital statistics, including births and deaths. Many states also require healthcare providers to report abortions and neonatal deaths. Federal and state laws mandate the reporting of communicable diseases, including venereal diseases. This exemplar discusses the nurse’s responsibilities related to mandatory reporting as well as the types of acts, events, and situations that are reportable.

Legal Requirements for Mandatory Reporting

In most states, nurses are required to report abuse or suspected abuse, certain types of injuries and illness, and crimes involving minors. Nurses have a legal obligation to report conduct that is incompetent, unethical, and illegal. This may include reporting violence, abuse, or neglect toward patients or other nurses and extends to reporting conduct involving third parties, including family members and other healthcare providers. Each state’s NPA includes requirements for reporting nurses who are in violation of the act.

As a general rule, when reporting situations involving patients, the nurse reports the required information through the administrative chain of the institution, beginning with the nurse’s immediate supervisor and the primary healthcare provider. All information reported is documented in the patient record. When reporting nurses who are in violation of the NPA, the nurse may be required to report the relevant facts to both the institution and the state BON.

Exemplar Key Terms

Good faith immunity, 2849

Mandatory reporting, 2849

Regardless of the situation, the nurse is not required to conduct any type of investigation or otherwise confirm that the suspected act or incident has, in fact, occurred. The nurse is required only to have a good faith suspicion based on information disclosed by a patient, physical symptoms observed in a patient, or the nurse’s personal observations of behavior on the part of a patient, colleague, or third party. The reporting nurse may be granted immunity from liability unless he or she knows that the report is false or acts with reckless disregard, without concern for the validity of the allegations made.

Good Faith Immunity

In every state, healthcare workers are protected from civil or criminal liabilities when they report suspected child abuse in good faith, even if the subsequent investigation does not make a determination of abuse. This is called **good faith immunity**. Good faith immunity also typically applies to reports of elder mistreatment, particular illnesses or injuries, and crimes involving minors.

When reporting incidents subject to good faith immunity, the nurse or healthcare provider may be required to disclose protected health information. This includes patient name, age, gender, race, residence, or present location as well as the nature and extent of the abuse, injury, or illness. Disclosure of this information under these circumstances is not considered a violation of the HIPAA Privacy Rule. Guidelines regarding disclosure of health information as a mandatory reporter are presented in **Box 49–6** >>.

SAFETY ALERT Good faith immunity applies only to required information that is reported to the appropriate agency or office. Information reported above and beyond that which is mandated may not be protected under good faith immunity.

Box 49–6

Guidelines Regarding Disclosure of Health Information

Depending on the setting, the nurse may be the only professional with firsthand information necessary for making an accurate report. General guidelines that nurses should follow regarding reporting health-related information include the following:

- Know the federal and state laws concerning duty to report.
- Report the required information to the appropriate governmental agency promptly.
- Comply with reporting laws in good faith.
- Follow agency policy carefully when making a report.
- Avoid a breach of confidentiality, and report only the information mandated.

Source: Based on Guido, G. W. (2014). *Legal and ethical issues in nursing* (6th ed.). Upper Saddle River, NJ: Pearson Education.

Mandatory Reporting of Abuse or Neglect of Minors and Older Adults

The circumstances in which a nurse must report child abuse vary among states. In most states, a report must be made when the nurse has reason to believe abuse has occurred because of things that are seen, heard, or observed in the work environment. In addition, nurses may be required to report knowledge or observation of a child being subjected to conditions that are likely to result in harm. Mandatory reporters must cite the facts or circumstances that led to their suspicions of abuse, but do not have the burden of proof (Child Welfare Information Gateway, 2016).

States also have specific laws pertaining to the mistreatment of adults and older adults (**Figure 49–6** »). These laws may be similar to those that govern the abuse and neglect of children. For example, many states generally offer good

Source: Jodi Jacobson/E+/Getty Images.

Figure 49–6 » Elder mistreatment includes physical, emotional, verbal, and sexual abuse and neglect.

faith immunity to individuals who report suspected abuse or neglect of an older adult or an adult with a disability. Nurses should know the laws of their individual states and their agency's policies for reporting suspected mistreatment of an adult or older adult (Daly, Klein, & Jogerst, 2012). Additional information on this topic can be found in the module on Trauma.

Mandatory Reporting of Certain Injuries and Illnesses

Primary healthcare providers are mandated to report certain types of injuries and illnesses to the appropriate authorities. Injuries and illnesses that typically fall under the reporting laws include the following:

- Bullet wounds, gunshot wounds, powder burns, or any other injuries arising or suspected of arising from the discharge of a gun or firearm
- Illnesses that appear to be caused by poisoning
- Injuries caused by, or appearing to be caused by, a knife or other sharp or pointed instrument if the physician or surgeon treating the individual suspects that a criminal act may have been involved
- Any wound, injury, or illness resulting in bodily harm as a result of a suspected criminal act or act of violence
- Infectious diseases, such as tuberculosis, HIV/AIDS, and *Escherichia coli* infection.

Most agencies have a policy and procedure in place for routine reporting of these injuries and illnesses. For example, injuries that are or appear to be due to violence are typically first seen in the emergency department; therefore, organizations typically designate the emergency department to report these injuries. A diagnosis of an infectious disease, on the other hand, may occur at any point in the healthcare interaction, so the nurse needs to be familiar with the agency policy for reporting infectious diseases and ensure that the report is made when warranted. As with abuse situations, good faith immunity typically applies.

Mandatory reporting of infectious conditions is a cornerstone of maintaining public health. Since 1878, the U.S. Public Health System has been collecting information on infectious conditions for the purpose of early identification and control of massive outbreaks, including, when necessary, instituting quarantines. High-profile diseases and threats of bioterrorism have brought renewed attention to this system of ongoing monitoring. The Centers for Disease Control and Prevention National Notifiable Diseases Surveillance System (NNDSS) has identified more than 50 infectious diseases in the United States that must be reported. Among these are anthrax, botulism, cholera, hepatitis, HIV infection, and syphilis.

Data are reported at the county level, with primary care providers reporting these diseases and conditions to local health departments. For diseases and conditions that must be reported within 24 hours, the initial report is made by telephone to the health department, and the written report is made within 7 days. Each county health department reports to the state's department of health, where data are managed and maintained. Data on many diseases and conditions are provided from the state level to the Centers for Disease Control and

Prevention, which publishes the *Morbidity and Mortality Weekly Report*. Although the law targets physician reporting, nurses need to be aware of the policies and procedures for reporting within their place of employment, especially nurses who are employed directly by their local health department.

>> Stay Current: Visit the National Diseases Surveillance System (NNDSS) website at <https://wwwn.cdc.gov/nndss> for more information. A complete list of the 2016 event codes of the NNDSS can be found at <https://wwwn.cdc.gov/nndss/case-notification/related-documentation.html#event-code-lists>.

Clinical Example D

Randy Wallace is a 6-year-old boy who is a first grader at Park Hills Elementary school, where Maya Anderson is the school nurse. One afternoon, Randy's teacher brings him to Miss Anderson's office because of an injury he sustained during recess. While tending to Randy's injury, Miss Anderson notices a number of bruises on Randy's arms in various states of healing. After dressing Randy's injury and sending him back out on the playground, Miss Anderson asks Randy's teacher about his bruises. Randy's teacher laughs and says, "Randy? He's my little daredevil. I can't turn my back on him for a second or I find him climbing up on desks, dancing across the radiator, or otherwise risking his life. His mom says he is the same way at home."

Critical Thinking Questions

1. Are Randy's injuries sufficient to produce good faith suspicion of child abuse? If not, what additional information might be necessary to produce good faith suspicion?
2. In what ways might the teacher's attitude about Randy's injuries suggest negligence by a mandatory reporter?

Mandatory Reporting of Nurses Who Are in Violation of the Nurse Practice Act

Not all instances of mandatory reporting by nurses involve patients; nurses must also report other nurses who are in violation of their state's NPA. Violations of the NPA and proper reporting procedures for violations are governed by the state BON. For example, North Carolina's General Statutes (NCGS § 90-171.47) mandate that any individual who has reasonable cause to suspect that a nurse is in violation of the NPA has the duty to report the relevant facts to the BON. BONs take these reports very seriously; as a result, their websites generally make reporting forms readily available. Employers typically use a different reporting form than that used by members of the general public.

The NPA spells out any formal action the board may take, and it usually requires clear and convincing evidence that the nurse has violated state nursing laws or rules. The nature of alleged violations varies widely, and cases are decided on their own merits. Many complaints are resolved through informal processes, though in some instances, a formal administrative hearing is held.

BONs are required to respect each nurse's right to due process. This ensures that the nurse is informed of any allegations regarding his or her practice, that the nurse has an opportunity to respond to and defend against the allegations, and that the matter is heard by a fair and impartial body.

REVIEW Mandatory Reporting

RELATE Link the Concepts and Exemplars

Linking the exemplar of mandatory reporting with the concept of trauma:

1. Why do you think nurses and healthcare providers have a duty to report injuries sustained during or as a result of a criminal act?
2. Why do you think mandatory reporting laws include the requirement to report injuries resulting from the discharge of a firearm?

Linking the exemplar of mandatory reporting with the concept of infection:

3. How do requirements and procedures for reporting HIV infection in your state or agency differ from requirements and procedures for reporting anthrax?
4. How do requirements and procedures for reporting shigellosis in your state or agency differ from requirements and procedures for reporting meningococcal disease?

REFLECT Apply Your Knowledge

Jenny Erickson, an 85-year-old woman who is a widow, came into the emergency department after she apparently fell at home. Her neighbor and friend, Elinor Jones, was waiting for Mrs. Erickson to go

to lunch with her and tried calling her several times. After getting no response for more than an hour, Mrs. Jones called the police, who found Mrs. Erickson on the kitchen floor. During the ED assessment, the nurse, Lynn Gutierrez, noted multiple bruises on Mrs. Erickson's legs, her upper arms, and both sides of her rib cage. When she asked Mrs. Erickson about the bruises, Mrs. Erickson said that she has been "falling a lot." The bruises were in several different stages of healing and bruised colors.

When Lynn asked whether she lived alone, Mrs. Erickson began crying and shivering. Mrs. Jones heard her friend crying and asked to speak with the nurse. Lynn spoke with Mrs. Jones away from the ED bedside. "I don't mean to get anyone in trouble, but Jenny has been living with her daughter and son-in-law for the past two years. I'm worried that they are upset having her there." Lynn realized that Mrs. Jones might have information that could explain why Mrs. Erickson had so many bruises. "Has Mrs. Erickson complained at all? I mean, has her family hurt her?" Mrs. Jones nodded her head. "I think so. I've heard her son-in-law yelling at her before, and Jenny had a big bruise on her forehead a month ago right after that."

1. What does the nurse need to do next?
2. How can the ED staff support Mrs. Erickson and ensure her safety while she is in the ED?
3. How can the nursing staff further assist Mrs. Erickson with the possible abuse?
4. What report must be done for this patient, and by whom?

Exemplar 49.E Risk Management

Exemplar Learning Outcomes

49.E Analyze risk management as it relates to legal issues.

- Explain the concept of risk management.
- Outline strategies for risk management.
- Explain the use of incident reports.

Overview

Risk management focuses on limiting a healthcare agency's financial and legal risk associated with the delivery of care, particularly in terms of lawsuits, ideally before incidents occur. Risk management is a process that identifies, analyzes, and treats potential hazards within a setting for the purpose of identifying and rectifying the hazards, thus preventing harm. Nurses play an important role in risk management because they are responsible for both patient safety and high-quality care.

Risk management focuses on areas at high risk for incidents, such as overall patient safety, medication administration, assessment and communication of allergies, and falls. The use of equipment and technology—including assessment of the functioning of equipment prior to use—also falls under the risk management umbrella.

Strategies for Risk Management

A facility may have an individual or a team dedicated to risk management. In most cases, there will be a designated risk manager whose overall role is to collaborate with the interprofessional healthcare team to maintain a safe and effective healthcare environment and prevent or reduce financial and legal risk to the organization (Kable, Guest, & McLeod, 2012).

Healthcare organizations can use several strategies to minimize risk. One of the most basic strategies is protecting against financial risk by purchasing insurance or by self-insuring. Other strategies involve identifying the areas in which incidents commonly occur and implementing practices to minimize the likelihood of incidents in these areas. Data collection, incident report systems, and staff education related to risk and documentation are all important for identifying and protecting against these types of risks. Strategies related to three common incident areas—implementing physician's orders, providing competent nursing care, and reducing pediatric medical errors—are discussed later in this section.

No matter how well an organization manages risk, incidents do still occur. Organizations should develop an investigation and reporting protocol for incidents that have the potential to result in lawsuits. When such incidents occur, investigation should begin as soon as possible after the incident.

Risk management strategies, reporting systems, and investigation practices should be regularly monitored and updated as needed. In addition, information gathered by

Exemplar Key Terms

Discovery, 2854

Risk management, 2852
Variances, 2854

reporting systems and via investigation should be used to educate staff in preparation for future incidents. For more information on how to prevent risk, see the modules on Quality Improvement and Safety.

SAFETY ALERT In addition to patient safety, healthcare organizations must consider risks to nonpatient visitors. These include community members and patients' family and friends. The organization can be found liable for falls and other accidents that occur on its property and should have proper protocols and risk management strategies in place for these occurrences.

Implementing a Physician's Orders

Nurses can minimize risk by analyzing procedures and medications ordered by the physician. It is the nurse's responsibility to seek clarification of ambiguous or seemingly erroneous orders from the prescribing physician. Seeking clarification from any other source is unacceptable and is regarded as a departure from competent nursing practice.

If the order is neither ambiguous nor apparently erroneous, the nurse is responsible for implementing it. For example, if the physician orders oxygen to be administered at 4 L/min, the nurse must administer oxygen at that rate and not at 2 or 6 L/min. If the orders state that the patient is not to have solid food after a bowel resection, the nurse must ensure that no solid food is given to the patient.

There are several categories of orders that nurses must question to protect themselves legally:

- **Question any order a patient questions.** For example, if a patient who has been receiving an intramuscular injection tells the nurse that the physician changed the order from an injectable to an oral medication, the nurse must recheck the order before giving the medication.
- **Question any order if the patient's condition has changed.** The nurse is considered responsible for notifying the physician of any significant changes in the patient's condition, whether the physician requests notification or not. For example, if a patient who is receiving an intravenous infusion suddenly develops a rapid pulse, chest pain, and a cough, the nurse must notify the physician immediately and question continuance of the ordered rate of infusion. If a patient who is receiving morphine for pain develops severely depressed respirations, the nurse must withhold the medication and notify the physician.

- **Question and record verbal orders to avoid miscommunications.** In addition to recording the time, the date, the physician's name, and the orders, the nurse documents the circumstances that occasioned the call to the physician, reads the orders back to the physician, and documents that the physician confirmed the orders as the nurse read them back.
- **Question any order that is illegible, unclear, or incomplete.** Misinterpretation of the name of a drug or the amount of a dose, for example, can easily occur with handwritten orders. The nurse is responsible for ensuring that the order is interpreted the way it was intended and that it is a safe and appropriate order.

Providing Competent Nursing Care

Nurses further minimize and manage risk by providing competent patient care. Nurses need to provide care that is within the legal boundaries of their practice and within the boundaries of agency policies and procedures. Nurses therefore must be familiar with their various job descriptions, which may be different from agency to agency. Every nurse is responsible for ensuring that his or her education and experience are adequate to meet the responsibilities delineated in the job description. If the nurse feels that his or her knowledge is inadequate, the supervisor or manager should be alerted.

SAFETY ALERT Competent care also involves protecting patients from harm. Nurses need to anticipate sources of patient injury, educate patients about hazards, and implement measures to prevent injury.

Application of the nursing process is another essential aspect of providing safe and effective patient care. Patients need to be assessed and monitored appropriately and involved in care decisions. All assessments and care must be documented accurately. Effective communication can also protect the nurse from negligence claims. Nurses need to approach every patient with sincere concern and include the patient in conversations. In addition, nurses should always acknowledge when they do not know the answer to a patient's questions, tell the patient they will find the answer, and then follow through.

Methods of legal protection for nurses are summarized in **Box 49–7** ».

Reducing Pediatric Medical Errors

Children are at a higher risk for medical errors than other patients and may also be more vulnerable to harm from errors because of their immature physiology (Tzeng et al., 2013). Reasons for increased medical errors among children include the following (Kaufman, Laschat, & Wappler, 2012; Tzeng et al., 2013):

- Medication dosage calculations for children are more complex than those for adults. Many medications are produced in adult concentrations that require dilution when given to a child, or the dosages need to be calculated based on weight or body surface area. This means that the optimal dose is based on mg/kg and divided by number of doses to be given a day. An additional problem is

Box 49–7

Guidelines for Legal Protection for Nurses

- Function within the scope of your education, job description, and nurse practice act.
- Follow the procedures and policies of the employing agency.
- Build and maintain good rapport with patients.
- Always check the identity of a patient to make sure it is the right patient.
- Observe and monitor the patient accurately. Communicate and record significant changes in the patient's condition to the physician.
- Promptly and accurately document all assessments and care given.
- Be alert when implementing nursing interventions, and give each task your full attention and skill.
- Perform procedures correctly and appropriately.
- Make sure the correct medications are given in the correct dose, by the right route, at the scheduled time, and to the right patient. Document the administration of the medication.
- When delegating nursing responsibilities, make sure that the individual who is delegated a task understands what to do and that the individual has the required knowledge and skill.
- Protect patients from injury.
- Report all incidents involving patients.
- Always check any order that a patient questions.
- Know your own strengths and weaknesses. Ask for assistance and supervision in situations for which you feel inadequately prepared.
- Maintain your clinical competence. For students, this demands study and practice before caring for patients. For graduate nurses, it means continued study to maintain and update clinical knowledge and skills.

that children often need suspensions or liquid preparations, adding to the dosage calculation complexity. Not only must the correct dose be calculated, but so must the amount of liquid preparation with that dose. Mistakes in mathematical calculations are one of the most common causes of medication errors.

- A misplaced decimal point in the medication dosage calculation can result in an overdose that can cause harm to the child or even death. This is particularly important for critically ill or injured children who do not have the reserves to deal with an overdose of medication.
- Many drug preparations require dilution to achieve the small dosage required by infants.
- Medications are sometimes prescribed that have not yet been approved by the FDA for use in children and for which pediatric standard dosage guidelines have not been established.
- Young children may be unable to communicate that they are having a reaction to the medication.

Another occasion of potential medical error involves families with limited English proficiency. There is a risk for errors in interpretation between the healthcare professional and the family member regarding care. For example, failure to obtain historical information about a drug allergy may lead to serious adverse effects. Even when a hospital interpreter

is used, errors such as omitting instructions on dose, route, frequency, and duration of medications have potentially harmful clinical consequences (AHRQ, 2012).

Incident Reports

As part of risk management, each healthcare organization has an incident reporting system (Kable et al., 2012). Nurses participate in this process by completing the required forms when they are involved in an incident and by following policies and procedures.

An **incident report** is an agency record of an accident or incident that occurred within the agency. It is designed to collect adequate information to assist personnel in preventing future incidents or occurrences. Incident reports are also called variance reports or unusual occurrence reports. Examples of occurrences that would be reported include medication administration **variances** (e.g., wrong medication, wrong dose, wrong route, wrong time, or omissions) and a patient or visitor falling.

In some jurisdictions, incident reports may be used in discovery. **Discovery** is the legal process of obtaining information before a trial. Although most incidents do not result in lawsuits, a nurse completing an incident report should always fill out the report as though it is discoverable. No language regarding liability should be included. The report should completely and accurately document the facts without

assumptions, conclusions, or blame. The report should include the patient's account of the incident in direct quotes and should identify all witnesses to the incident. Incident reports generally include the following:

- Names and identifying information of any patients and healthcare personnel involved in the incident as well as information on witnesses (if any)
- The location, time, and date of the incident
- Equipment or medication involved (if medication, state the medication's name and dosage).

Although the event that prompted the incident report is noted in the patient's chart, there should be no entry in the patient's chart to indicate that an incident report was completed. For example, if the patient was given the wrong medication, the actual administration of the medication will be noted in the patient's chart. If the patient required any treatment as a result of the event, that also is noted in the patient's chart (Guido, 2014).

Nurses engage in risk management by following ANA standards of care and practice, by following their employing agency's policies and procedures, and by working collaboratively to ensure that patient safety is maintained at all times. Risk management is required of every nurse every day in the course of practicing nursing.

REVIEW Risk Management

RELATE Link the Concepts and Exemplars

Linking the exemplar of risk management with the concept of assessment:

1. How does a thorough assessment of a patient contribute to risk management?
2. Nurses are required to do their own assessment of a patient after receiving a report during shift change or patient transfer. How might failure to conduct this assessment or failure to do it in a timely manner affect the patient's risk for adverse outcomes?

Linking the exemplar of risk management with the concept of communication:

3. How does a change-of-shift report minimize the nurse's risk for professional negligence or malpractice?
4. How does accuracy in documentation contribute to risk management?

REFER Go to Pearson MyLab Nursing and eText

REFLECT Apply Your Knowledge

Three nurses were getting ready for the shift change report outside the room of an older adult patient. Kim Nelson whispered to the other

two nurses, "The doctor ordered the wrong dosage for Mr. Stivers. It took more than an hour to get in contact with her to clarify the order."

Randy Carson shook his head, knowing that this had become a common problem on their unit. "So, Kim, did she finally fix the order?"

Kim sighed and said, "Yes, but it didn't end there. Shortly after I gave Mr. Stivers the medication, he had difficulty breathing."

Pam Troy felt worried about this. She had been a nurse for only 2 years, but she knew that any problems when a medication is given are of critical concern. "Well, was it still the wrong dosage?"

Kim avoided looking at the other two nurses. "I need to get ready for report."

Randy was also concerned. "Wait, Kim. What happened?"

"Okay, so then I found out he's allergic to the medication I gave him."

Pam spoke up again. "Are you going to do an incident report?"

Kim shook her head. "No, I don't want to be sued or lose my job."

1. Is this case an example of nursing negligence? Explain.
2. What is the evidence that this issue may need an incident report?
3. What further information should the nurse seek before reporting an error?
4. Who else needs to know that there was a medication error with the patient?

The Institute of Medicine (IOM) (2001) has defined **quality** as “the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge.” In addition, high-quality care involves “providing patients with appropriate services in a technically competent manner, with good communication, shared decision making, and cultural sensitivity.”

Improving the Quality of Healthcare

One way in which nurses can provide high-quality care is participating in quality improvement and quality management. **Quality improvement** consists of “systematic and continuous actions that lead to measurable improvement in healthcare services and the health status of targeted patient groups” (Health Resources and Services Administration [HRSA],

2011). **Quality management** includes evaluation of medical and nursing processes for quality and effectiveness compared to accepted standards in order to correct problems before they harm patients and to prevent errors in treatment. Quality management also aims to provide cost-effective care by preventing overuse, misuse, and underuse of medical resources.

In its report *To Err Is Human: Building a Safer Health System*, the IOM (2000) stated that medical errors account for approximately 98,000 deaths per year. Since the report’s release, multiple studies have investigated the incidence of preventable medical errors. An updated study was conducted in 2011, and the estimated rates of medical errors were found to be closer to a range of 210,000–400,000 preventable deaths per year (James, 2013). This puts medical errors as the third leading cause of death. Medication errors alone are often studied, and a recent systematic review study found that overall medication error rates are occurring at a median rate of 19.6–25.6% (Keers et al., 2013).

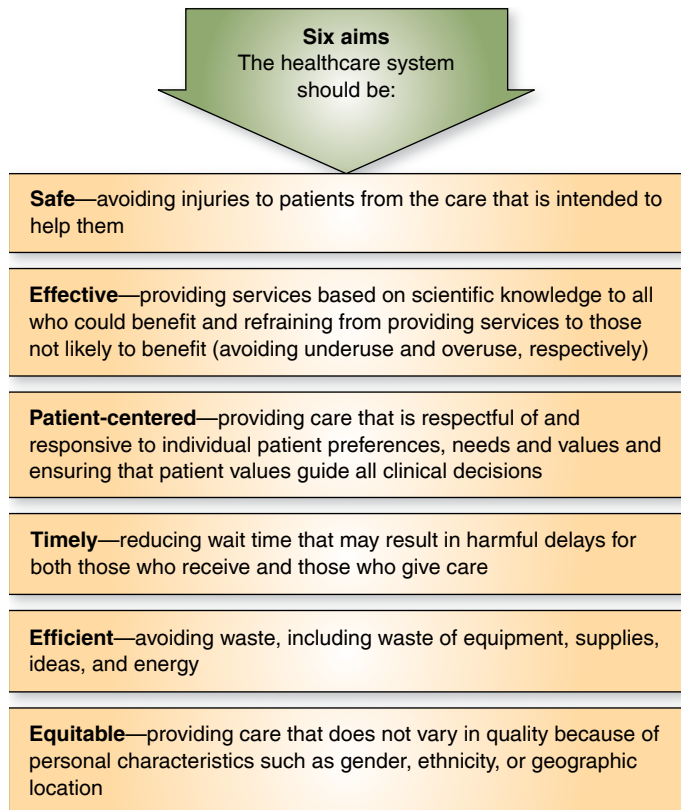

Figure 50-1 » Six aims for improving the healthcare system.

In 2001, the IOM released a follow-up report entitled *Crossing the Quality Chasm: A New Health System for the 21st Century*. This report concluded that the current healthcare system was too disorganized to adequately care for individuals with multiple chronic illnesses. The report suggested that a new healthcare system should be developed that improves care, partly through the use of rapidly advancing technology. In an effort to improve the healthcare system, *Crossing the Quality Chasm* proposed six aims for improvement: The healthcare system should be safe, effective, patient-centered, timely, efficient, and equitable (**Figure 50-1** »).

National Initiatives

Following the IOM reports, the healthcare industry began to embrace quality improvement. The need to improve patient safety and health outcomes and to implement changes to support these improvements was obvious to individuals working at every level of healthcare. State and federal governments have also contributed to initiatives aimed at improving the quality of healthcare.

Federal Initiatives

Governmental agencies such as the U.S. Department of Health and Human Services (USDHHS), physicians' groups such as the American Medical Association, and professional nursing organizations such as the American Nurses Association (ANA) have developed indicators of high-quality care and measures to document the quality of care. Three important efforts are the development of the National Database of

Nursing Quality Indicators (NDNQI), the publication of *Patient Safety and Quality: An Evidence-Based Handbook for Nurses*, and the development of National Patient Safety Goals by The Joint Commission. These programs and documents aim to collect and provide data that identify areas for improvement and encourage facilities to meet quality goals.

More recently, the Patient Protection and Affordable Care Act (PPACA), commonly known as the **Affordable Care Act (ACA)**, was passed by Congress and signed into law by President Barack Obama on March 23, 2010. This 906-page law, along with its thousands of pages of regulations, was enacted in an attempt to make healthcare affordable for all Americans. Some of these changes included expanding and reforming Medicaid and Medicare; incentives to reduce 30-day readmission rates; and incentives to reduce wasteful spending by healthcare facilities. Changes to the healthcare system that are detailed in the ACA began implementation in 2010 and may continue into 2020. However, healthcare laws are constantly changing, and the ACA may be changed significantly in the coming years.

» **Stay Current:** Keep abreast of the changes in healthcare and insurance laws by visiting the U.S. Department of Health & Human Services at <https://www.hhs.gov/healthcare/about-the-aca/index.html> and Medicaid.gov at <https://www.medicaid.gov/affordable-care-act>

To improve the health of the population, the USDHHS (2015) has developed the National Quality Strategy, which contains three broad aims:

- **Better Care:** Improve the overall quality by making healthcare more patient centered, reliable, accessible, and safe.
- **Healthy People/Healthy Communities:** Improve the health of the U.S. population by supporting proven interventions to address behavioral, social, and environmental determinants of health in addition to delivering higher-quality care.
- **Affordable Care:** Reduce the cost of quality healthcare for individuals, families, employers, and government.

To achieve these aims, the National Quality Strategy will focus on six priorities (**Box 50-1** »).

State and Local Initiatives

Even with the advent of the ACA, states are partially responsible for providing state health insurance programs for low-income individuals and families. The ACA offers states the option of implementing a basic health program (BHP) for low-income adults and legal immigrants. Under the BHP, states contract with health plans and providers to provide at least the minimum essential benefits under the ACA, and the federal government helps to subsidize the program (Henry J. Kaiser Family Foundation, 2013).

Quality Initiatives

A review of the first 5 years of the ACA has found some improvements in the quality of healthcare, although it is too early to determine whether the trends will continue and whether the improvements are related to the new laws or to other initiatives that were already ongoing. Overall 30-day readmission rates for Medicare patients have declined by

Box 50–1

Six Priorities for High-Quality Care

1. **Patient Safety:** Making care safer by reducing harm caused in the delivery of care.
2. **Person- and Family-Centered Care:** Ensuring that each person and family is engaged as partners in their care.
3. **Care Coordination:** Promoting effective communication and coordination of care.
4. **Effective Prevention and Treatment:** Promoting the most effective prevention and treatment practices for the leading causes of mortality, starting with cardiovascular disease.
5. **Healthy Living:** Working with communities to promote wide use of best practices to enable healthy living.
6. **Affordability:** Making quality care more affordable for individuals, families, employers, and governments by developing and spreading new healthcare delivery models.

Source: From Agency for Healthcare Research and Quality (AHRQ). (2015a). *2015 national Healthcare Quality and Disparities Report and 5th anniversary update on the National Quality Strategy*. Retrieved from <http://www.ahrq.gov/research/findings/nhqrd1/nhqrd15/index.html>

over 1%, and the incidence of hospital-acquired conditions is also showing a decline. Many healthcare organizations have signed up for bundled payment options, which should reduce costs, and early reports show a stabilization in healthcare expenditures (Blumenthal, Abrams, & Nuzum, 2015).

Concepts Related to Quality Improvement

Some ways in which healthcare quality can be improved include properly using advance directives, following privacy laws, and striving to reduce errors. Quality improvement uses a variety of methods to improve care, including the use of evidence-based practices and quality improvement methods adopted from industry. Quality management programs track overall patient progress on certain key indicators such as infection rates, fall rates, and incidence of pressure injuries to determine how well patients are cared for and what measures need to be taken to improve care on the unit. If new devices are used on the unit for the prevention of pressure injuries, they are tracked by the quality department to determine whether pressure injury rates decline. Patients' records are also used to track quality measures called core measures, and certain key measures are tracked to make sure patients are being discharged with the appropriate medications and follow-up for conditions such as stroke and myocardial infarction.

Safety culture is important to monitor, and many health systems use the Agency for Healthcare Quality and Research's (AHRQ) Patient Safety Culture Survey to monitor the safety culture to evaluate how staff perceive the environment and if they are comfortable reporting errors so improvements can be made. Patient-centered care is also an important area for safety. Including patients' preferences is an important area to support high-quality care. Selected concepts integral to quality improvement are outlined in the Concepts Related to Quality Improvement feature. They are presented in alphabetical order.

The Quality Improvement Process

Quality improvement is a continuous multistep, multilevel process that identifies areas for improvement based on performance and industry standards. Quality improvement involves analyzing current protocols of care and their associated outcomes, comparing those outcomes to the outcomes of leaders in high-quality care (**benchmarking**), identifying areas for improvement, researching factors that contribute to better outcomes, and implementing changes to improve outcomes. Patient outcomes must then be analyzed to determine the effectiveness of the changes and identify areas for further improvement. In addition, if a facility consistently provides a better quality of care than similar facilities do, the facility that is demonstrating excellence is responsible for documenting its methods to help improve care at other facilities. When quality improvement is directly linked to the performance of an individual, team, unit, or organization, it is called **performance improvement**.

Analysis of Current Protocols and Outcomes

To begin quality improvement, an individual, unit, or facility must understand its baseline performance records. Performance can be assessed on an intraprofessional level or an interprofessional level. In addition, it can focus on patient outcomes, cost effectiveness, resource utilization, or the integration of these aspects of care.

Intraprofessional Assessment

Intraprofessional assessment occurs within a group of individuals who have similar positions within a healthcare system, such as a group of nurses or a group of surgeons. Such an assessment is important for identifying areas of improvement at each level of care. Intraprofessional assessment includes peer reviews, audits, and outcomes management.

Peer Reviews

A **peer review** is used to professionally critique a colleague's work on the basis of predetermined standards. This allows nurses to assess other nurses in a safe, nonpunitive environment. Using this process, nurses are together able to analyze complicated cases and determine the standards by which they will collectively be held accountable. It also allows issues to be discussed by those with firsthand knowledge and produces recommendations that the nursing staff will understand and accept.

Audits

An **audit** is an examination of records to verify accuracy and proper use. An audit usually examines financial or medical records, and the audit can be for a single patient, a group of similar patients, an individual clinician, a unit, or a whole facility. If the audit is focused on one discipline (e.g., nursing), it is an intraprofessional assessment. If the audit is focused on multiple disciplines (e.g., both nurses and physicians), it becomes an interprofessional assessment.

In nursing, most audits are either retrospective or concurrent. A **retrospective audit** is performed after a patient's discharge. It compares care provided to one patient with care

Concepts Related to Quality Improvement

CONCEPT	RELATIONSHIP TO QUALITY IMPROVEMENT	NURSING IMPLICATIONS
Ethics	Patients have the right to the best quality of care.	<ul style="list-style-type: none"> ■ Anticipate the need to provide high-quality care to all individuals, regardless of race, gender, sexual orientation, or ability to pay for services. ■ Be aware of disparities in treatment among population groups; advocate for high-quality care for all individuals. ■ Consult with patients to determine their preferences for care; provide culturally competent care. ■ Be aware of patient preferences that are not ethical, such as refusal of lifesaving blood transfusions for a child.
Informatics	Electronic health records can be used at the point of care and can be easily transmitted to collaborating healthcare workers to improve continuity of care.	<ul style="list-style-type: none"> ■ Accurately record a patient's medical history and results of diagnostic tests for current and future use and to share patient information with relevant healthcare providers. ■ Realize the importance of keeping all electronic and paper records up to date. ■ Provide education on the use of electronic records at the point of care. ■ Use informatics to identify areas for improvement, such as tracking healthcare-associated infections or identifying geographic locations that are without adequate healthcare resources.
Legal Issues	Consistently following federal and state laws will improve the quality of patient care.	<ul style="list-style-type: none"> ■ Be alert to potential abusive situations; quality of care can be improved by preventing future abuse. ■ Be alert to behavior of healthcare workers (including one's self) that could increase risk of harm to patients or violate any patient's privacy; seek to counsel individuals performing reckless acts. ■ Anticipate asking patients or family members about legal documents such as living wills, healthcare proxy, preference for do not resuscitate (DNR) orders. ■ Avoid blaming healthcare workers for inadvertent mistakes that result in patient harm; instead, console the individual and provide education on how to avoid future errors. ■ Participate in efforts to improve laws and healthcare protocols and treatments.

provided to patients with similar conditions, and recommendations are made to change procedures if needed. A **concurrent audit** is performed while the patient is still undergoing care at the healthcare facility. It is used to evaluate the adequacy of the nursing care the patient is receiving and to determine whether desired outcomes are being met. This allows changes to be made, if needed, to prevent adverse events or improve the patient's care.

Outcomes Management

Outcomes management uses patient experiences to guide improvement in all areas of healthcare by providing a link between medical interventions and health outcomes and between health outcomes and cost of care. An outcomes management system implements evidence-based practices, guides case decision making, incorporates better and more efficient clinical management, and provides information to improve services (Hodges & Wotring, 2012). Outcomes management can be used both to discover areas for improvement and to analyze areas of excellence to determine factors that contribute to success or failure. In 2004, the National Institutes of Health (n.d.) began an outcomes management program called PROMIS (Patient Reported Outcomes Measurement

Information System) that collects information from patients to measure their health status in the areas of physical, mental, and social well-being. This program continues to provide clinicians with access to patient-reported information about the effectiveness of treatments and the symptoms that patients experience to help improve communication, manage chronic diseases, and design treatment plans.

Interprofessional Assessment

Patient care involves collaboration among providers in multiple disciplines. For example, a patient with obesity and type 2 diabetes who is recovering from bariatric surgery may require care from a surgeon, a physician, a nurse, and a dietitian. To collaborate effectively, these individuals must have efficient communication, coordination, and integration of care. An **interprofessional assessment** (or interdisciplinary assessment) involves more than one discipline such as nursing and physical therapy.

In addition to peer reviews, audits, and outcomes management, interprofessional assessments include utilization reviews. A **utilization review** analyzes the use of resources to identify areas of overuse, misuse, and underuse. This protects the facility from unnecessary and inappropriate use of

resources. Utilization review is required by Medicaid for specific services and by The Joint Commission for facility accreditation. A utilization review may identify areas in which resources are being overused, such as urinary catheterization for incontinent patients who are ambulatory, or areas in which resources are lacking, such as inadequate staffing.

Clinical Example A

Ruth Davison is a 74-year-old woman who has been admitted to the same-day surgery center for elective right carpal tunnel repair (CTR). One hour before surgery, Mrs. Davison receives cefazolin (Ancef) 1 g IV as a prophylactic antibiotic. Anesthesia for the procedure consists of injection of local anesthetic at the surgical site with no administration of sedation.

After completion of the CTR, Mrs. Davison is stable, awake, and alert. She is monitored in the postanesthesia care unit (PACU) for 1 hour. Once she meets all discharge criteria, she is prepared for discharge to her home. Mrs. Davison's discharge instructions include keeping her surgical dressing in place for 2 days, after which time she may remove the dressing. She is further instructed to keep the dressing clean and dry while it is in place and to immediately report any drainage noted on the dressing. Mrs. Davison also is instructed to immediately report any redness, drainage, or swelling noted at her incision site following dressing removal. She is further advised that her sutures are absorbable and, thus, do not need to be removed. After verbalizing understanding of her discharge instructions and signing the discharge record, Mrs. Davison is transported to her home by her daughter.

The following morning, the same-day surgery center receives a phone call from Mrs. Davison, who reports that she has removed her dressing and now notes "a little" bleeding and redness at her incision site. After reviewing Mrs. Davison's discharge record, the nurse reminds Mrs. Davison that her instructions included leaving her dressing in place for 2 days. Mrs. Davison states that she does not recall being told to leave her dressing intact for 2 days and asks, "How was I supposed to be able to tell if the wound looked okay with the dressing covering it?" She further notes that she is concerned that her surgical wound may be infected.

Mrs. Davison is scheduled for a follow-up appointment with her surgeon that afternoon. At her follow-up appointment, Mrs. Davison's wound is evaluated and cleansed, and a dressing is reapplied. Her surgeon instructs Mrs. Davison to return to his office in 3 days, at which time her dressing will be removed and her wound will be reevaluated for signs and symptoms of infection.

As a result of Mrs. Davison's apparent misunderstanding of her discharge instructions and subsequent need for two additional appointments with her physician, an intraprofessional assessment is initiated. Two registered nurses who provided care to Mrs. Davison, two additional registered nurses, and the nurse manager review Mrs. Davison's case. They compare Mrs. Davison's case to the cases of patients of similar age, cultural background, and surgical procedure. The nurse manager also follows up with Mrs. Davison to hear her perspective on the care she received, her understanding of the discharge instructions, the symptoms she experienced, and her overall satisfaction with her care.

Critical Thinking Questions

1. Identify the portions of the intraprofessional assessment that reflect peer review, auditing, and outcomes management.
2. Why is it important to compare Mrs. Davison's care with care received by other patients who correctly followed discharge instructions?
3. Describe the impact that a patient's perspective can have on quality improvement.

Benchmarking

Benchmarking is a method that is used to compare the performance of an individual or organization to industry standards. **Standards** of care are based on established models of high-quality performance and may reflect the performance of industry leaders, scientific or clinical research, or recommendations of professional organizations such as the ANA. These standards are continually being updated, so nurses must use research and other reliable sources of information to stay up to date on current recommendations and standards.

The Donabedian model of quality improvement (originally developed by physician and researcher Avedis Donabedian) states that standards usually relate to three dimensions of high-quality care: structure, process, and outcome. **Structure standards** relate to material resources, human resources, and general organizational structure. They focus on the organization's capacity and systems for providing care. **Process standards** focus on the steps used to lead to a particular outcome. They are used to determine whether a set of steps exists and whether those steps are being followed. **Outcome standards** focus on the performance of a process, such as the number of bedridden patients who develop a pressure injury (Joint Commission Resources, 2012).

Benchmarking uses **indicators**, or statistics, that reflect the organization's performance in a specific area, to compare the quality of care within the organization to industry standards. Indicators must be measurable, objective, and sensitive to changes in performance. Indicators can include generic or specific standards of care as stated by the ANA, specialty organizations, or the organization or unit implementing quality improvement strategies.

For example, a nursing unit decides to evaluate the quality of the care provided to newly admitted patients. The unit determines that the indicators for the study will be a completed initial assessment within 1 hour of admission, a documented and accurate nursing plan of care by the end of the shift, and accurate implementation of physicians' orders. The indicators are then compared against each newly admitted patient's medical records to benchmark the frequency with which the indicators were met. The nurses on the unit will be informed if the study indicates that the nursing care provided does not comply with the standards for the unit.

Targeting Areas for Improvement

Once the current level of performance has been compared with industry standards, areas that need improvement can be identified. On the basis of the policies and procedures already in place, each healthcare facility will have different areas in need of improvement. These may reflect general practices such as use of a specific ointment for wounds or specific practices such as frequency of checking vital signs on older patients after pacemaker implantation. They may be identified on the basis of a bad outcome for one patient or a trend of poor outcomes for multiple patients. Some areas needing improvement are identified as a result of a required investigation after adverse events such as sentinel events and breach of care. Risk management can also be used to identify risk factors and develop associated protocols for reducing or preventing adverse events.

Sentinel Events

The Joint Commission (2013) has defined a **sentinel event** as “an unexpected occurrence involving death or serious physical or psychologic injury, or the risk thereof. Serious injury specifically includes loss of limb or function. The phrase ‘the risk thereof’ includes any process variation for which a recurrence would carry a significant chance of a serious adverse outcome.” Sentinel events require immediate investigation and response. In an effort to continuously improve the safety and quality of healthcare provided to the public, The Joint Commission reviews a facility’s response to sentinel events as part of its accreditation process. The goals of the sentinel event policy are to have a positive impact on patient care, prevent sentinel events, understand the factors that contributed to the event, increase the general knowledge about sentinel events, and maintain the confidence of the public in accredited organizations.

If a sentinel event occurs, accredited organizations are expected to respond appropriately, including conducting a credible **root cause analysis** (problem solving to identify the root cause of faults), developing a plan to reduce future risk of sentinel events, implementing improvements, and monitoring the effectiveness of improvements (The Joint Commission, 2013). In addition, The Joint Commission conducts reviews for a specific subset of sentinel events, including the following:

- Unanticipated death or major permanent loss not associated with the patient’s original illness
- Invasive procedures on the wrong patient, at the wrong site, or with the wrong procedure
- Unintended retention of a foreign object in a patient after surgery
- Radiation overdose or delivery of radiation to the wrong body region
- Administration of an incompatible blood transfusion
- Abduction, rape, assault, homicide, or suicide of any patient or staff member while at the healthcare facility or suicide within 72 hours of discharge
- Unanticipated death of a full-term infant
- Discharge of an infant to the wrong family.

Breach of Care

A **breach of care** or **breach of duty** occurs when a nurse deviates from the standard of care. Guido (2014) states that this occurs when the nurse does something that should not have been done (e.g., gives the incorrect medication) or does not do something that should have been done (e.g., fails to administer a scheduled medication). Thirty years ago, malpractice suits involving nurses were rare; in recent years, they represented about 5% of the medical malpractice payment reports (HRSA, 2013). These suits are usually related to deficits in treatment and care management, assessment, monitoring, professional conduct, and medication administration (in order of frequency). An analysis of closed cases revealed nurses failing to identify a worsening pressure injury or failing to contact a physician for additional treatment in the assessment category. In the monitoring category, failure to monitor vital signs in postoperative patients was

found. The medication administration category has seen a reduction in number of incidents, but those that have occurred are more severe (Nurses Service Organization, 2015).

Quality improvement efforts seek to determine weaknesses in procedures and processes as well as organizational issues that can affect nurses’ ability to provide nursing care consistent with established professional standards of care. Nurses can reduce the risk of committing a breach of care by reporting problems to nursing supervisors, remaining current in their skills and education, basing all care on the nursing process model, and documenting care provided as well as the patient’s response to interventions (Guido, 2014). Following these procedures reduces the risk of an adverse event and resulting malpractice suit.

Risk Management

Risk management is “the process by which vulnerabilities are identified and changes are made to minimize the consequences of adverse patient outcomes and liability” (Raso & Gulinello, 2010, p. 26). Risk management includes both proactive components to prevent adverse events and reactive components to minimize damage from adverse events. Risk assessment must occur daily, and all individuals must be dedicated to keeping patients safe from harm.

The risk management process identifies risks that may lead to patient or staff injury or financial loss; reviews systems that monitor risks, such as patient questionnaires or incident reports; analyzes the frequency, severity, and cause of past adverse events; analyzes new procedures with potential risk to patients; stays up to date on current laws pertaining to healthcare; and identifies the need for patient and staff education. Using this information, the risk management team can identify areas of risk and implement strategies to reduce risk as much as possible.

Because of their close contact with patients, nurses are perfectly positioned to analyze patient satisfaction, identify specific patient risks, and implement strategies at the bedside to reduce patient risk of an adverse event. Patient satisfaction is a key factor in risk management, because a dissatisfied patient presents a higher risk for liability than a satisfied patient. A nurse who becomes aware of patient dissatisfaction should take steps to communicate with the patient to clarify misunderstandings, advocate for the patient to receive better care, and notify a supervisor about potential problems. Personal care by a nurse and a nurse manager can calm a patient or the patient’s family, identify problems before they become an emergency, and improve the quality of care. (For more information, see the exemplar on Risk Management in the module on Legal Issues.)

Clinical Example B

At an extended care facility, Reuben Meyers, an 84-year-old man with Alzheimer disease, was discovered to be missing from his bed at 2:15 a.m. A search resulted in finding Mr. Meyers lying in the street, the victim of a hit-and-run motor vehicle accident. He was unconscious when he was found, and a physical assessment identified a right hip injury, which later was revealed to be a fractured right hip. He also had a 2-inch-long open gash in the right temporal region of his head. After closure of his head wound and surgical repair of his hip, Mr. Meyers remained unconscious until his death 12 days later. An investigation found that security cameras had recorded Mr. Meyers wandering

from the extended care facility at 1:30 a.m. Traffic cameras recorded the hit-and-run accident at 2:08 a.m.

Critical Thinking Questions

1. On the basis of the limited description of this sentinel event, what standards of nursing care may have been breached?
2. What potential legal ramifications may this event have for the nurses who were caring for Mr. Meyers and for the nursing home facility?
3. Develop a risk management program to identify risks for similar sentinel events, and propose strategies to improve the quality of care and reduce the risk of wandering outdoors for patients with Alzheimer disease.

Identifying Factors That Promote Better Outcomes

Identification of problem areas or adverse events demands intervention to improve patient safety. This involves a planning process that identifies the cause of adverse events through a root cause analysis and researches the literature for methods of improvement. Nurses can participate with a team of other clinicians to plan the changes needed to improve the quality of care. Organizations such as The Joint Commission identify patient safety goals every year for organizations to focus on. The 2017 goals include ensuring patients are identified safely (e.g., right patient; see the module on Safety), improving staff communication (see the module on Communication), using alarms safely, and preventing infections (see the module on Infection) (The Joint Commission, n.d.). Nursing has a role in impacting all of these goals to promote better patient outcomes. Additional factors that promote better outcomes are summarized next.

Root Cause Analysis

A root cause analysis is required by The Joint Commission for sentinel events and is recommended for any adverse event. The goals of the root cause analysis are to identify the reasons for failures or problems and to develop an action plan for improvement to decrease the likelihood of future adverse events. This analysis focuses on systems and processes, not on individual performance, and it analyzes both special causes (factors that cause variation beyond what is normal) and common causes (factors that occur because of normal variation in the system). The action plan should include identification of who is responsible for implementing and overseeing improvements, pilot testing to ensure the success of the changes, timelines for implementing changes, and strategies for measuring the effectiveness of changes (The Joint Commission, 2013).

Reducing Medication Errors

The National Coordinating Council for Medication Error Reporting and Prevention (n.d.) defines a medication error as “any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the healthcare professional, patient, or consumer.” An adverse drug event (ADE) is defined as harm experienced by a patient as a result of exposure to a medication. Not all ADEs are the result of a medication error, but about half of ADEs are preventable. One of the highest-risk drugs used in the inpatient setting is anticoagulant intravenous

Box 50–2

Methods to Reduce Medication Errors

Nurses can implement several methods to reduce medication errors, including the following:

- Double check the “seven rights” *every time* medication is administered: right assessment, right individual, right medication, right dose, right time, right route, and right documentation.
- Have a second nurse check the medication order.
- Check known allergies before administering medication to a patient.
- Avoid disruptions and distractions during medication administration duties.
- Verify tubing placement (e.g., IV, chest, NG) before administering drugs or nutrition.
- Document and understand the interactions among *all* medications a patient is taking, including over-the-counter medicines, herbal remedies, and nutritional supplements.
- Do not combine medications with the same active ingredient.
- Always check a child’s weight before medication administration to ensure correct dosing.
- Consult with the prescriber of the patient’s medication and possibly a pharmacist if unsure about a medication order.
- Maintain a current resource to reference for drugs that are not familiar.
- Provide thorough education to patients about the use of all medications.
- Conduct medication reconciliation at every transition in care.
- Use smart infusion pumps for intravenous medications.

heparin. The Institute for Safe Medication Practice (ISMP) maintains a list of high alert medications such as look-alike, sound-alike medications to assist clinicians with identifying medications that can either look similar or have similar names, but that have very different chemical properties that can cause harm to the patient if the medications are mixed up. Another group of high-alert medications are medications that can cause problems in older adults, such as benzodiazepines and oral antidiabetic agents (AHRQ, 2015b).

Several national- and facility-implemented interventions have been designed to decrease medication errors, including barcoding both patients’ identification bands and medications, regulating similar names of drugs that may cause confusion, and using a computerized physician order entry system. Many other interventions specifically help nurses prevent medication errors (**Box 50–2** >>>).

Staffing Practices in Nursing

Multiple studies have established a link between decreased nurse staffing and adverse patient outcomes. One consideration of nurse staffing is the nurse-to-patient ratio (quantity). One systematic review found that an increased number of nursing hours was associated with reduced inpatient mortality (Shekelle, 2013). Readmission rates are also improved with better staffing. A study of Medicare patients from California, New Jersey, and Pennsylvania found that readmission rates in patients with heart failure, pneumonia, and myocardial infarction increased when nursing workload increased (McHugh & Ma, 2013). Nursing skill is also a critical factor related to patient outcomes (quality). One

Box 50–3**Nursing-Sensitive Indicators**

Nursing-sensitive indicators reflect the quantity and quality of nursing care in the areas of structure, process, and outcome (Jones, 2016; NDNQI, n.d.).

Structure	Process	Outcome
<ul style="list-style-type: none"> ■ Nursing hours per patient day ■ Nursing turnover ■ RN education/certification ■ Nursing skill mix (RN, LPN/LVN, UAP, agency staff) 	<ul style="list-style-type: none"> ■ Pain assessment, intervention, reassessment (AIR) cycles completed ■ Peripheral intravenous infiltration rate ■ RN job satisfaction ■ RN Practice Environment Scale (PES) 	<ul style="list-style-type: none"> ■ Healthcare-associated infections (e.g., catheter-associated UTI, central line-associated bloodstream infections, ventilator-associated pneumonia) ■ Patient falls (with or without injury and injury level) ■ Pressure injury rate (community-, hospital-, or unit-acquired) ■ Psychiatric physical or sexual assault ■ Physical restraint prevalence ■ Patient satisfaction

study found that an increase in the ratio of LPN hours to total nursing hours was associated with an increase in mortality and sepsis in trauma patients (Glance et al., 2012). Nursing-sensitive indicators are measured by many healthcare systems as part of the NDNQI. The NDNQI was established by the ANA in 2007 to evaluate linkages between staffing and quality of care (Montalvo, 2007). The original database was managed by the University of Kansas; however, in 2014 the database was sold to Press Ganey, a leader in the industry of performance measurement, including patient care satisfaction (ANA, 2014). Currently Press Ganey has combined the NDNQI with patient experience and nurse engagement to provide nursing (Press Ganey, n.d.) and other leaders with a comprehensive set of quality data that allow them to gain insights into where there are areas that need improvement and where things are going well. The NDNQI indicators are listed in **Box 50–3** >>.

Resource Utilization

The value of healthcare can be increased by reducing costs while maintaining or improving the quality of care. This can be accomplished by implementing measures to reduce waste that may result from unnecessary or inefficient services, prices that are too high, excess administrative costs, missed prevention opportunities, and medical fraud (IOM, 2010). Examples of waste that are directly applicable to nurses include medical errors that result in prolonged inpatient days, scheduling an additional visit for patient education only, and lost time because of unorganized supplies, poorly maintained equipment, or inadequate documentation.

Blame-free Environment

According to the IOM's report *To Err Is Human* (2000), most errors in healthcare are a result of the healthcare system and not the fault of any single individual. If a clinician is afraid to report errors for fear of punishment or because reporting does not result in positive change, then problems within the system cannot be identified and addressed. Therefore, a key component in quality improvement is establishing a **blame-free environment** in which healthcare providers can report errors or near misses without the fear of punishment (AHRQ, 2012). This helps identify problems so corrections

can be made and future adverse events can be prevented. The Evidence-Based Practice feature discusses methods for reducing errors and increasing the reporting of errors.

Just Culture

One difficulty in establishing a blame-free environment is that whereas many errors are a result of the healthcare system, some errors are the result of personal mistakes and demand accountability. **Just culture** attempts to balance the blame-free environment with appropriate accountability by focusing on correcting problems that lead individuals to engage in unsafe behavior while maintaining individual accountability by establishing zero tolerance for reckless behavior (AHRQ, 2012). Just culture differentiates among human error, at-risk behavior, and reckless behavior, in contrast to the “no blame” approach of the blame-free environment. Just culture is based on the understanding that errors are often the result of system failures rather than human failures. It recognizes that an atmosphere of punishment impedes error prevention by promoting intimidation and secrecy rather than shared accountability. Just culture focuses on the system rather than the individual while still maintaining an environment of individual accountability for both front-line staff and leaders and managers. This is critical; when front-line staff fail to report safety errors because of a fear of suspension or termination, healthcare managers may develop an inaccurate understanding of the care provided by the organization. This hampers ongoing quality improvement efforts, further risking patient safety (Dekker & Breakey, 2016). Successfully establishing an environment of just culture requires that leadership encourage proactive system management as well as individual accountability. It also requires that employees consider themselves stakeholders and act to establish and maintain the just culture environment. Just culture does not, however, accept or tolerate gross misconduct (e.g., employees working under the influence of alcohol or narcotics) or conscious disregard of patient and staff safety.

In a just culture environment, each member has the responsibility to take action to prevent errors and also to respond to errors, recognizing that errors are more often the result of system failures than individual error, and that when individual

Evidence-Based Practice

Methods to Reduce Errors

Problem

The most effective way to identify and correct problems in health-care is by consistently reporting errors and potential errors/near misses so that they can be learned from. However, studies indicate that safety climate and safety culture and clinician willingness to report errors are linked (Weaver et al., 2013).

Evidence

One method to reduce medical errors is to eliminate barriers to error reporting. The primary reasons that healthcare workers do not report errors are the fear of being blamed and the fear of being punished (Gorini, Miglioretti, & Pravettoni, 2012). Other reasons include increased time associated with paperwork, a fear of lawsuits, self-perceptions of incompetence, embarrassment or guilt about the mistake, reluctance to incriminate other providers, lack of knowledge about what constitutes an error or how to report errors, and lack of feedback when errors are reported (Hartnell et al., 2012). In addition, many clinicians do not realize that near misses and errors that do not cause harm should also be reported.

Another method to reduce medical errors is to improve the nurses' work environment. The American Association of Critical Care Nurses (AACN) has established six standards for a healthy work environment: skilled communication, true collaboration, effective decision making, appropriate staffing, meaningful recognition, and authentic leadership (AACN, n.d.). In addition, fostering a safety culture can lead to decreased errors and increased reporting. A recent systematic review of interventions to promote safety

cultures found that a combination of interventions such as patient safety rounds, implementation of best care practices, teamwork interventions, and continuous learning improves patient safety and quality (Weaver et al., 2013).

Implications

Eliminating barriers to error reporting and establishing a healthy work environment can lead to reduced errors and increased reporting of errors. However, changing from the current culture of blame to a safety culture will require time and dedication from the entire organization. As individuals on the front line of patient care, nurses play a critical role in the establishment of a safety culture by helping to identify problems and by working to implement changes to practice that will reduce errors. Education about a blame-free environment and taking personal responsibility to report errors are two ways in which nurses can contribute to quality improvement in healthcare.

Critical Thinking Application

1. Consider situations in which you, a fellow nurse, or a physician makes medication errors that do not result in patient harm. In which situations would you complete an error report? Why?
2. Identify personal barriers that would prevent you from reporting a medical error caused by the system, a coworker, or yourself.
3. Research the current error reporting systems in place at a local hospital, nursing home, and primary care clinic.

error does occur, it is more likely to be accidental than willful or neglectful. For example, if the hospital pharmacy dispenses the wrong medication or the wrong dosage or if the department in charge of stocking supplies for a unit fails to make an appropriate inventory and orders an inadequate amount of supplies, those errors may result from inadequate systems as much as from individual carelessness.

As more organizations begin to embrace just culture, front-line staff are likely to feel more support from management in critical areas, including staffing. From time to time, however, nurses and other front-line staff may find themselves in situations in which management is unresponsive to suggestions for improvement or reporting of critical shortages or potential for errors related to patient safety. In these cases, staff may find themselves in the awkward position of needing to report these problems outside the agency.

Personal Responsibility

All nurses must be involved in quality improvement. The nursing student demonstrates concern for quality by making a commitment never to perform an act that the student is uncertain how to perform, by showing accountability for his or her actions, and by admitting to errors if they occur. Each nurse, whether a nursing student or a practicing nurse, has the responsibility to know the policies and procedures in the facility where clinical training is performed and to follow them exactly. In addition, nurses are responsible for understanding how to report errors, including paperwork that should be completed and individuals to whom errors should be reported.

Implementation of New Protocols

When a problem has been identified and a plan has been put in place to improve the quality of care, that plan must be implemented. The most important step in implementing new procedures is educating nurses and other clinicians about the importance of the new process, the steps involved, and associated reporting procedures. Education can take place in large or small groups, as a self-study, or during orientation. Each individual must then take personal responsibility to implement the needed changes to improve the quality of care.

Evaluation of Efficacy of New Protocols

Finally, the implemented changes must be evaluated to assess their impact on patient care, patient outcomes, patient and clinician satisfaction, and resource utilization. Data related to the original problem must be collected and are then analyzed on the basis of the benchmark standards to determine whether standards are being met. This process is called **quality assurance**. If standards are not met, the quality improvement is continued with the goal of achieving the desired goals.

Quality Management Programs

The process of quality improvement is accomplished through use of a quality management program. A quality management program must include both information about current practices and outcomes and accountability for the

individuals who oversee and perform patient care. Advances in technology are vital to quality management, because clinical information systems (see the module on Informatics) can be used to track patient outcomes and actions that led to patient harm. For example, data from a clinical information system can be used to track the occurrence of healthcare-associated infections, including the location of the infection (e.g., urinary system, respiratory system, skin), frequency of patient assessment, materials used to treat the patient, and other relevant factors. Changes in hand hygiene protocols, equipment and medical supplies used, wound care protocols, and patient placement can then be implemented to reduce the incidence of healthcare-associated infections. To be successful, these changes must then be accepted and used by the entire staff.

Healthcare organizations use different quality management programs depending on their clientele and specialty area. Commonly used quality management programs include total quality management, continuous quality improvement, Six Sigma, and Lean Six Sigma. Each of these programs includes a comprehensive quality management plan.

Comprehensive Quality Management

A quality management plan is used to help healthcare facilities integrate new programs, models, and technologies with the primary care services that are already in place. The plan should address needs of engagement (improving the experience of care), population health, and value (per capita costs). The plan should be comprehensive, looking at quality and safety in clinical, managerial, administrative, and facility-related aspects of the organization. It should design, implement, monitor, and improve methods to increase the quality of care in keeping with the organization's mission and core values. Most organizations will develop quality management plans that require cooperation between departments as well as unit-specific plans.

Quality management plans should be patient focused, collecting and evaluating data for improvement of patient outcomes, expectations, and satisfaction. Patient satisfaction surveys can be used to track the effectiveness of changes from the patient's perspective. Nurses often perform this follow-up through personal visits, forms, or phone calls. If any problems are noted, the nurse can then report back to the healthcare provider or nurse manager to help improve patient care.

Total Quality Management

Total quality management (TQM), a comprehensive management philosophy that was invented by Walter Shewhart and made famous by W. Edwards Deming, is used to improve quality and productivity by using data and statistics to improve systems processes. The hallmark of TQM is that it involves teamwork throughout the organization, involving all departments and employees and including both suppliers and customers. Its essential elements include communication, feedback, fact-based decision making, and a focus on continual improvement.

A system of quality improvement most often associated with TQM is Deming's **Plan-Do-Study-Act (PDSA, Figure 50-2 >>)**, which was modified from Shewhart's Plan-Do-

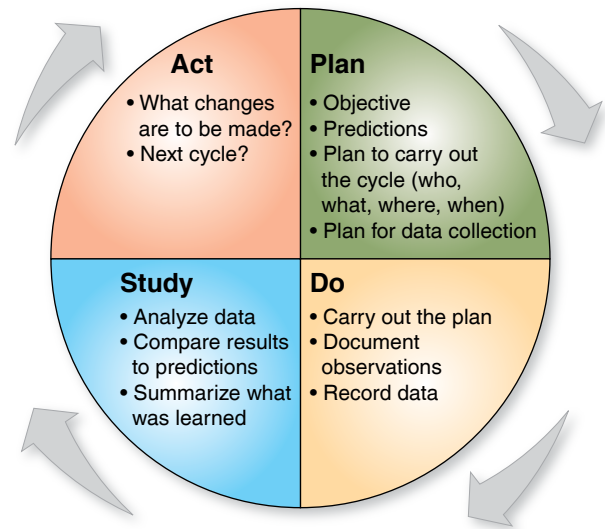

Figure 50-2 >> PDSA cycle.

Check-Act or Plan-Do-Check-Adjust (PDCA). During planning, individuals on the TQM team define the goal, collect data, and outline a strategy to reach the goal. In the Do phase, the plan is implemented on a small scale to determine whether it will be effective. This is followed by the Study phase, in which the outcomes of the Do phase are analyzed and compared to the expected outcomes. In the Act phase, the team must decide whether the goal was met, plan further changes, and decide whether the original goal is attainable based on the results of the previous interventions. If the goal was met, then the team must decide whether the changes should be implemented throughout the organization.

Continuous Quality Improvement

In healthcare, **continuous quality improvement (CQI)** is defined as "a structured organizational process for involving personnel in planning and executing a continuous flow of improvements to provide quality health care that meets or exceeds expectations" (Sollecito & Johnson, 2013, p. 4). CQI can be applied to a specific problem, development and implementation of policies and procedures, resource utilization, or implementation of evidence-based practices.

CQI is a customer-driven process. In healthcare, the customer can be internal or external to the system. **Internal customers** include employees of a healthcare organization, such as nurses, physicians, therapists, medical record staff, billing specialists, and other employees. **External customers** include the individuals who seek healthcare as well as their family members and significant others. External customers also include other individuals and entities with whom internal patients interact, such as insurance companies, managed care organizations, equipment or material suppliers, social service agencies, and law enforcement officials. Customer satisfaction is the end goal of CQI. CQI is also system focused, emphasizing system errors rather than individual errors. Therefore, CQI requires involvement by everyone

with knowledge of the system, from senior management to individuals providing everyday care to patients (Sollecito & Johnson, 2013).

Clinical Example C

An unidentified middle-aged woman is transported to the emergency department (ED) by two law enforcement officers. The officers report that the individual was observed “wandering around on a highway” and that complaints were received from passing motorists about the woman’s behavior. The officers also report that, upon their arrival, the woman was unable to provide any identification, nor was she verbally responsive to their questions. She did, however, willingly seat herself in their squad car upon request. The officers state that the woman is being transferred to the ED for evaluation, as they are uncertain about the etiology of her behaviors.

Lynne Bryten, RN, is the ED triage nurse. The unidentified woman, who is clutching a doll, appears to be awake and alert. She is clean and dressed appropriately, and her tennis shoes appear to be relatively new. Ms. Bryten attempts to perform an initial interview, but the woman does not respond to her questions. She permits Ms. Bryten to assess her vital signs, all of which are within normal limits. She exhibits no apparent indications of traumatic injury, and her pupils are equal and responsive to light. Although the woman is not verbally responsive to Ms. Bryten’s questions, she appears to follow directions during the assessment. The woman is admitted to the ED as an unidentified patient. Ms. Bryten escorts the patient and the law enforcement officers into the ED and notifies the ED physician of their arrival.

Dr. Terrence Garvinner, the attending ED physician, receives Ms. Bryten’s report. Upon entering the patient’s room, he introduces himself and performs a brief patient assessment. The patient remains verbally unresponsive, but she follows Dr. Garvinner’s directions. Afterward, Dr. Garvinner asks the law enforcement officers to speak with him privately. They accompany him to an empty ED room.

Dr. Garvinner informs the law enforcement officers that the patient does not appear to have any physical injury; rather, she may be developmentally delayed. He suggests that the officers check missing person reports and contact residential treatment centers to determine whether or not the patient may have wandered away from one of the local residential care centers. Dr. Garvinner questions the officers as to why they did not use this approach initially. One of the officers responds, “We have no way of knowing if she has a medical problem. That’s why we brought her here. Plus, we have other calls coming in—we’re swamped.” Dr. Garvinner responds, “We have no way of identifying this woman. She appears to be a vulnerable adult who may be lost. We have a full waiting room, but we don’t have staff available to serve as detectives. I believe you have an entire department dedicated to performing detective work.”

Critical Thinking Questions

1. Identify the internal and external customers in this scenario.
2. Summarize the conflict between the law enforcement officers and the ED physician. Is either argument correct? Why or why not?
3. In the context of healthcare, how can conflict between internal and external customers affect the patient who is seeking treatment or in need of assistance?
4. What additional external customers may be helpful in identifying the patient and assisting with her safe return to her residence?
5. How might the process of quality management be applied to address and manage future situations such as the one described in the scenario?

Six Sigma

Six Sigma is a quality improvement program that was originally implemented by Motorola and General Electric to reduce variation within a process to produce a near-perfect product. Sigma is a Greek letter often used to measure deviation from a standard; to receive a sigma level of 6, only 3.4 products per million are allowed to be defective. In this system, a defect is defined as anything that could lead to patient dissatisfaction. Defects in healthcare could range from relatively minor problems such as providing the wrong size gown to a patient to major problems such as performing an amputation on the wrong limb. Six Sigma primarily uses the **DMAIC** system to improve outcomes (Mason, Nicolay, & Darzi, 2015):

Define the problem, determine a goal, and form a team to address the problem.

Measure: Obtain data related to the current process, the problem, and the desired goal.

Analyze: Look at the data to determine cause-and-effect relationships related to the problem.

Improve: Develop solutions to problems and implement those solutions.

Control: Implement measures to sustain positive changes and continuously monitor the process to ensure goals are being met.

Six Sigma may also use the DMADV methodology: Define, Measure, Analyze, Design, and Verify.

Six Sigma uses teams of individuals with intimate knowledge of the problem and training in Six Sigma principles. Master Black Belts are experts in Six Sigma who can assist in data calculations and function as a resource for the team. The team is led by a Black Belt with extensive knowledge of Six Sigma. Green Belts are team members with some experience with Six Sigma, and Yellow and White Belts are relatively new to the Six Sigma system. Six Sigma is most successful when the entire organization, including both administrators and clinicians, is involved in planning and implementing changes.

Multiple studies have illustrated the success of the Six Sigma system in healthcare. In one study, a 92.6% rate of hyponatremia for postoperative kidney transplantation patients was improved to a 92.2% rate of normal serum sodium levels after application of Six Sigma principles (Leaphart et al., 2012). In another study, implementation of Six Sigma principles decreased patient transfer times from general medical floors to a critical care area by almost 60%, resulting in increased customer satisfaction, improved utilization of resources, a decreased risk of adverse events, and better economic profit (Silich et al., 2012).

Lean Six Sigma

Lean Six Sigma combines the strategies of Six Sigma, described above, with the Lean system. The objective of the Lean system is to eliminate waste to maximize value. Waste is defined as anything that does not bring value to the customer. Therefore, Lean Six Sigma is a methodology used to reduce waste and provide consistency in the quality of care. It primarily uses the DMAIC system that is used in Six Sigma.

REVIEW The Concept of Quality Improvement

RELATE Link the Concepts

Linking the concept of quality improvement with the concept of collaboration:

1. How can the nurse use conflict management skills to resolve patient or family member dissatisfaction with care?
2. How does strong interprofessional team communication improve the outcomes of total quality management?

Linking the concept of quality improvement with the concept of managing care:

3. How does an effective quality improvement process reduce the cost of care?
4. How does proper care coordination improve the quality of care provided to patients?

REFLECT Apply Your Knowledge

Jose Hernandez is a newly graduated nurse who has successfully passed the NCLEX-RN and has accepted a job working on a busy

genitourinary unit in the local community hospital. During orientation, he is working the evening shift with a preceptor. On this particular evening, the unit has been very busy, and the charge nurse asks Jose's preceptor, Fred McFarlane, to take a few patients in addition to acting as a preceptor for Jose with his assigned patients. Fred agrees and instructs Jose to seek him out if he needs help or has any questions.

Quite by chance, Jose notices that Fred makes a medication error when he fails to administer an ordered medication at an appropriate time to one of Fred's assigned patients. Jose doesn't say anything because Fred acknowledges the error independently, but Jose isn't sure what to do at the end of the shift when he realizes that Fred is not going to fill out an incident report.

1. Should an incident report be filled out regarding Fred's late administration of a medication to the patient if no harm resulted? Explain the rationale for your answer.
2. Who is responsible for completing an incident report if one is required? Explain.
3. What is Jose's responsibility related to the error if he had no care responsibility related to the patient who received the medication later than ordered?
4. How would you handle this situation if you were Jose?

Module 51

Safety

Module Outline and Learning Outcomes

The Concept of Safety

Attributes of Safety

51.1 Analyze the attributes of safety.

Alterations to Safety

51.2 Differentiate common alterations of safety.

Concepts Related to Safety

51.3 Summarize the relationship between safety and other concepts.

Health Promotion

51.4 Explain the promotion of health safety.

Nursing Assessment

51.5 Differentiate common assessment data used to examine safety.

Independent Interventions

51.6 Explain independent interventions that can be implemented for the patient's safety.

Collaborative Efforts

51.7 Summarize collaborative efforts used by interprofessional teams and patients for safety in healthcare settings.

Safety Exemplars

Exemplar 51.A Health Promotion and Injury Prevention Across the Lifespan

51.A Analyze health promotion and injury prevention across the lifespan as they relate to safety.

Exemplar 51.B Patient Safety

51.B Analyze safety as it relates to patients in home care and healthcare settings.

Exemplar 51.C Nurse Safety

51.C Analyze safety as it relates to being a nurse.

>> The Concept of Safety

Concept Key Terms

Attributes of safety, 2872	Quality, 2872	Safety culture, 2880
National Patient Safety Goals (NPSGs), 2880	Quality and Safety Education for Nurses (QSEN), 2880	Standard precautions, 2877
Never event, 2872	Safety, 2872	

How important is the quality of safety in healthcare settings? Is it only essential in an acute healthcare facility? Or extended healthcare facility? What about healthcare at a community setting? Or in a patient's home? When quality and safety are not priorities in healthcare settings, safety records reflect increases in accidents, errors, injuries, and infections. Statistics about patients in healthcare settings reflect that every year, 1 of 25 patients acquires a healthcare-associated infection; a patient on Medicare has a 1 in 4 chance of experiencing harm, injury, or death when admitted to a hospital; and every day more than 1000 patients will die as a result of preventable harm or adverse events (Hospital

Safety Score, 2015). Many of these adverse occurrences could have been prevented.

Is safety limited to patients, or does it also include the healthcare workforce? It is a safety issue when the patient is left in a tightly tied wrist restraint throughout the night shift without being checked and complains of tingling and numbness below the restraint. But what about the patient with congestive heart failure who is on a salt-free diet but who is being given packs of salt from staff? Don't accidents just happen sometimes? As in the example of an elderly patient who was told not to get out of bed without help, but who does, and then trips over a towel left on the floor, falls, and

fractures a hip. Or the nurse in a hurry who forgets to perform hand hygiene after changing a patient's IV dressing and before moving to the next patient who needs a Foley catheter inserted. What about chemical exposure, attacks of violence, needlesticks, and musculoskeletal injuries nurses may receive? Who is responsible to be alert for safety hazards like these, and where is the safety net to avoid errors, prevent infections, and stop accidents? Are they all from faulty systems or conditions, or are people a big part of the problem, too?

Attributes of Safety

Unsafe situations related to the quality of safety can occur in healthcare facilities, homes of patients, and community settings. **Safety** refers to decreasing risks of dangers or hazards to prevent accidents, injuries, mistakes, and harm. **Quality** relates to the level of performance consistent with current evidence that increases efficiency and effectiveness for desired safety outcomes (Agency for Healthcare Research and Quality [AHRQ], 2013). It requires everyone in a healthcare facility to engage in safe behaviors and have awareness of surroundings to protect against unsafe situations and prevent safety hazards.

Attributes of safety are the qualities or properties of remaining safe. They are the precautions individuals take to be safe and prevent adverse occurrences. Examples of attributes or precautions healthcare facilities can implement to improve quality and safety include the following (Occupational Safety and Health Administration [OSHA], 2015):

1. Schedule hazard surveys and safety/health inspections in all areas.
2. Implement an effective hazard reporting system available to employees.
3. Investigate all safety incidents for root causes.
4. Perform job hazard analysis for all departments.
5. Keep safety, health rules, and work practices readily available.
6. Have applicable OSHA-mandated safety programs in place.
7. Make sure personal protective equipment (PPE) is being used effectively.
8. Ensure appropriate housekeeping is properly maintained.
9. Confirm the facility has disaster plans for internal and external emergency situations.
10. Analyze workplace injury/illness data.
11. Promote the performance of safety and health responsibilities through organizational policies.
12. Provide safety and health training for all levels of employees at least annually.

Active partnership between healthcare staff and patients is an effective way to maximize the quality of safety and minimize risks of hazards and errors resulting in accidents and injuries. Everyone positively or negatively impacts safety and quality in the healthcare environment, including patients. Nurses need to encourage patients to:

- Be assertive to actively speak up and ask questions about medications, therapies, tests, and procedures to know the “what” and “why” of these and anticipated results.

- Be knowledgeable about their condition or illness and have awareness of how to prevent complications while in a healthcare facility.
- Have a support person to assist in these areas and be vigilant about the safety of care for the patient.
- Practice safe behaviors such as washing hands appropriately, asking for help when needed, eating appropriate foods on their prescribed diet, and reporting any mistakes noticed to the nurse or another staff member.

Healthcare employees need to be competent in and willing to use a range of safety skills. They also need to have the ability to identify safety hazards, take responsibility for correcting them, and be part of the solution to prevent them from happening again. Quality improvement and risk management of health services within healthcare concentrate on identifying and making changes to improve quality and safety for everyone (see the module on Quality Improvement for more information).

Alterations to Safety

Nurses play a major role as safety gate keepers, but even still, sometimes tragic adverse events happen, assessments may be incomplete, or a step or two during a procedure may be skipped. Even unintentional mistakes may result in longer hospital stays, accidents, injuries, infections, functional decline, or death. **Figure 51-1** » illustrates how sometimes decisions made may seem to make sense at the time, but later can negatively impact patient safety.

In some cases, catastrophic adverse events serve as motivators for prevention, spurring healthcare facilities, advocacy organizations, and even families to act to try to prevent tragic events from happening to others. Small safety initiatives may grow into national initiatives using public service announcements, social media, and other forms of media communication. This can help build awareness of how routine procedures can quickly become life-threatening safety hazards within healthcare facilities. An example of one such initiative is *CampaignZERO*. This initiative advocates for patient safety by providing patients and their family members free checklists to use when admitted to a healthcare facility to help remain safe until discharge. The checklists have items listed that support patient safety and quality of care to help prevent **Never Events**, which are preventable hazards that can result in injury or death and that should never happen to patients (CampaignZERO, 2014). A checklist may give information about a given topic, such as pressure injuries or falls, what to do to avoid complications, how to notice something is wrong, how to talk with the physician, when to notify a nurse for help, and how to ask appropriate questions. Never events are considered sentinel events by The Joint Commission. See the Concept of Quality Improvement for a discussion of sentinel events.

» **Stay Current:** Visit the website of the Patient Safety Movement to see the checklists from CampaignZERO: <http://patientsafety-movement.org>.

Another national initiative from the CDC and the Safe Injection Practices Coalition began after an investigation was completed on multiple cases of hepatitis exposure. Evidence showed that the problem stemmed from basic infection

Three Nurses Making Decisions About a Patient's Safety

First: Read about Tammy, our patient.

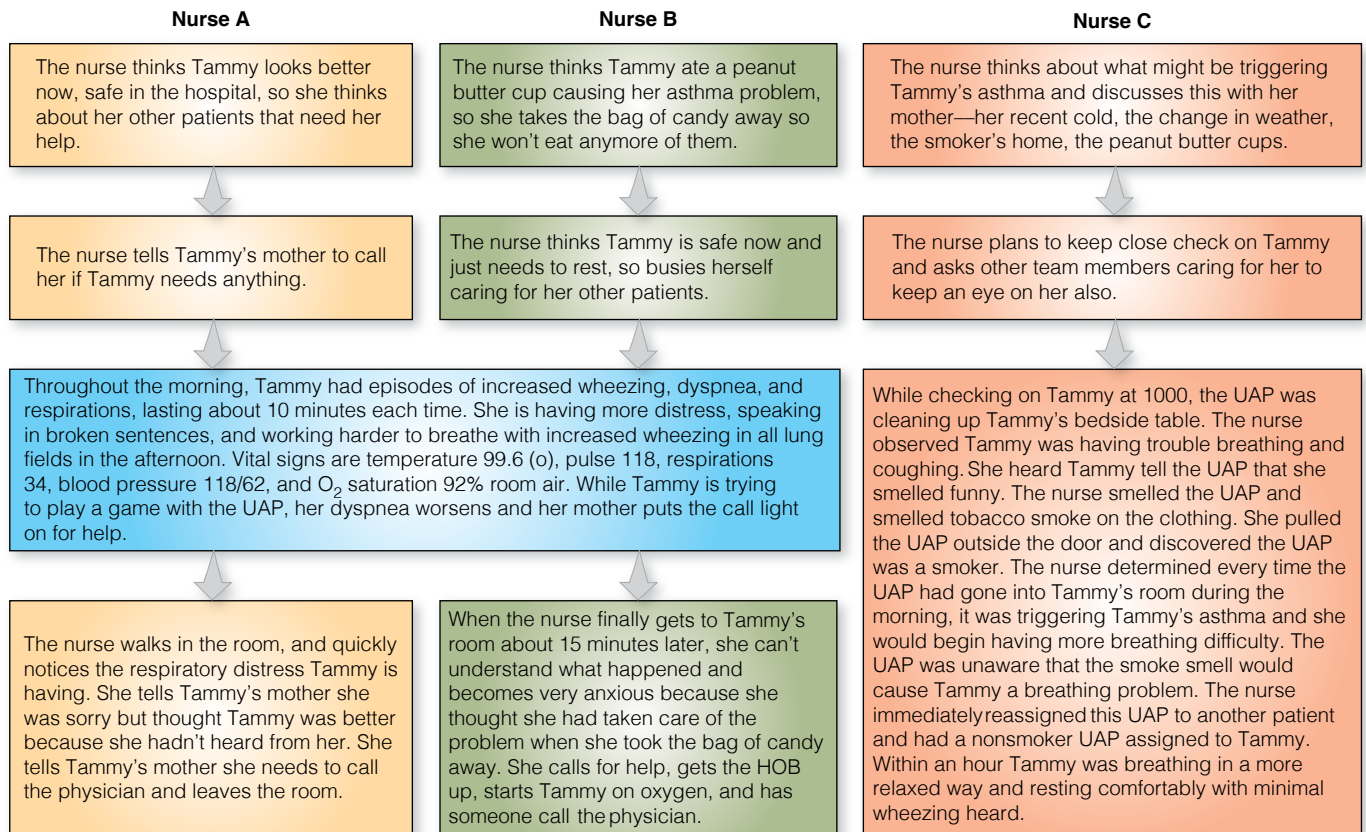

Tammy Odom is a 6-year-old patient with a history of bronchial asthma. Tammy is 40 inches tall, weighs 42 pounds, and is allergic to peanuts. She was admitted through the emergency department at 0200 this morning with acute exacerbation/bronchitis. Tammy's mother, Mrs. Odom, told the nurse that Tammy had a cold a few days ago. She also said that Tammy had been at her friend's house spending the night. At approximately 1900, the friend's mother called her and told her that Tammy had to use her rescue inhaler and still was having a hard time breathing. At that time, she found out the friend's father smokes in the house. Mrs. Odom said the recent drop in temperature may also have contributed to Tammy's breathing problems and reported that Tammy is allergic to peanuts and shellfish.

The nurse making rounds before breakfast notes the following assessment data: temperature 99.2°F (o), pulse 112, respirations 26, blood pressure 112/52, O₂ saturation 95% on room air, minimal wheezing bilateral lower lobes, no retractions or use of accessory muscles for respirations, and speaking in whole sentences. Tammy tells the nurse about the bag of candy her friend gave her the night before. When looking at the candy, the nurse notes some peanut butter cups and explains to Tammy she should not eat them because of her allergy to peanuts. Tammy says she is saving those for her mother who likes them, but that she has not eaten any of them. The nurse notes an empty wrapper in the candy bag. An unlicensed assistive personnel (UAP) is assigned to help Tammy and her mother as needed.

Answer the following questions:

1. What else do you want to assess about Tammy's situation and physical condition?
2. What do you suspect as the trigger of her asthma exacerbation? Why?
3. What is your priority intervention at this time?

Second: Read about nurses A, B, and C.

Answer the following questions:

4. At what point do you consider Tammy safe from respiratory distress from her asthma? Explain.
5. What was the faulty thinking from Nurse A? Nurse B?
6. Nurse C used reasoning based on significant cues to make a clinical judgment about what was triggering Tammy's respiratory distress. Can you follow her critical thinking process?
7. What should Nurse C say to the UAP with smoke in her clothing?
8. Can you identify eight mistakes in thinking or lack of knowledge in this scenario? How would they have been avoided?
9. What were the consequences for Tammy due to decisions by Nurse A and Nurse B?
10. What were the benefits for Tammy due to decisions by Nurse C?

Figure 51-1 >> Three nurses making decisions about a patient's safety. This is a scenario looking at perspectives of three different nurses based on decisions they make about the same situation. Follow the directions and answer the questions.

control inconsistencies involving the unsafe medication administration practice of reusing syringes, which caused contamination of medication vials used on subsequent patients. The coalition developed an initiative called *One Needle, One Syringe at One Time*, whose goal is to eliminate adverse events resulting from unsafe injection practices. Since its inception, this initiative has notified more than 130,000 patients of potential exposure to hepatitis or HIV related to unsafe medication administration (One and Only Campaign, 2014).

» **Stay Current:** Visit the One and Only website at <http://www.oneandonlycampaign.org/> to learn more about this campaign.

Healthcare facilities can help decrease adverse events by using a three-pronged approach to quality and safety for everyone. The first prong is the organization's support for keeping quality in safety a priority by promoting a safety culture that encourages all employees to intentionally and actively make safe choices in what they do and how they do it as they keep a mind-set for quality of safe practice. A nonprofit organization, the Leapfrog Group, ranks the safety of hospitals around the country with letter grades (**Box 51-1** »).

The second prong is the involvement and sustainability of healthcare employees to consistently choose to follow health safety rules and standards for the environment, patient care, and be safety advocates for others. Healthcare employees are needed to responsibly maintain the safe environment and care within a facility. The last prong is encouragement given to patients to be actively engaged in every aspect of their care throughout their course of stay. They need to ask questions about the quality and safety of procedures done, medications administered, or other care provided to them.

Box 51-1

Hospital Safety Scores Reflecting Alterations to Safety

The Leapfrog Group uses the Hospital Safety Score to rank general acute care healthcare facilities on how safe they are for patients. This not-for-profit organization is composed of companies and private healthcare companies that want healthcare in the United States to be safe, have high quality, and be affordable by promoting transparency and value-based incentives to healthcare facilities. The 28 performance measures used in the scoring process are from AHRQ, CDC, Centers for Medicare and Medicaid Services (CMS), and the Leapfrog Hospital Survey.

These 28 measures are divided into two categories, process/structural measures and outcome measures. These safety scores are publicly reported through the annual Leapfrog Hospital Survey (Hospital Safety Score, 2015). Scores for more than 2500 acute care healthcare facilities throughout the United States are available. Consumers of healthcare are encouraged to consider safety when selecting a healthcare facility for procedures, surgeries, and hospitalizations, which can serve as an incentive for healthcare facilities to make safety more of a priority.

» **Stay Current:** Visit <http://www.hospitalsafetyscore.org/what-is-patient-> to see the 28 measures and to find the safety score of your local hospital.

Concepts Related to Safety

Every area of nursing is related to safety. Many nursing actions, such as hand hygiene and patient identification validation, promote well-being and safety for patients and others. As partners in their own plans of care, patients can participate in safety behaviors such as infection control, fall precautions, and accident prevention. Nurses also ensure their own safety by following policies and procedures, by engaging in therapeutic communication that promotes patient self-esteem and reduces patient anxiety, and by using critical thinking to prioritize patient care. The Concepts Related to Safety feature links some, but not all, of the concepts integral to safety. They are presented in alphabetical order.

Health Promotion

In the United States, there is a collaborative effort of several federal agencies to improve the nation's health. Workplace promotion programs are offered to employees at many companies and organizations that include wellness programs about nutrition, smoking cessation, stress management, and safety. Individuals can select from a variety of wellness, exercise, weight management, and stress management programs available to meet their own needs (see the module on Health, Wellness, Illness, and Injury for more information). Health promotion practices are given in **Table 51-1** ».

» **Stay Current:** Follow individual state laws on child passenger safety seats for infants and children at http://www.ghsa.org/html/stateinfo/laws/childsafety_laws.html.

Nursing Assessment

Patients admitted to healthcare facilities initially undergo a comprehensive nursing assessment, including observation, an interview, and a physical examination. As a proactive measure, this initial assessment includes specific age-appropriate questions and observations that focus on safety needs. All healthcare settings will have their own safety checklists based on recommendations of healthcare organizations such as The Joint Commission. Risk-based assessment data help to identify patients who may require special precautions to prevent harm and minimize consequences from debilitation or exacerbation of a preexisting risk while in healthcare settings. This assessment process can further be divided into three levels based on patient responses: low, medium, or high safety risk.

Observation and Patient Interview

During initial interviews with patients, nurses may use checklists quickly to identify physical, psychologic, and emotional areas to further explore for potential safety issues or health promotion needs. For example, if the patient is asked, "Have you ever noticed blood in your stool?" and the patient responds, "Yes," the nurse should then explore this with the patient. If the patient responds "Yes, sometimes" to the question, "Have you ever thought about hurting yourself?" the nurse takes this seriously and assesses the patient's current risk for suicide or self-harm.

In addition to gathering assessment data through the interview, nurses are constantly observing patients for age-appropriate assessment data such as communication

Concepts Related to Safety

CONCEPT	RELATIONSHIP TO SAFETY	NURSING IMPLICATIONS
Accountability	<ul style="list-style-type: none"> Unsafe nursing practice, behaviors, and thinking could cause harm to patients and others, and if not addressed, will continue to occur. 	<ul style="list-style-type: none"> Unsafe nursing practice should be reported and addressed. Competency in providing quality safe nursing care develops when following standards of care.
Advocacy	<ul style="list-style-type: none"> Vulnerable populations may unintentionally make unsafe decisions about their healthcare. Sometimes unethical, immoral, or illegal actions result in unsafe treatments and behaviors by professionals. 	<ul style="list-style-type: none"> Nurses can support patients in making safe appropriate decisions by providing accurate and complete information using their primary language to help them understand the decision to be made. Nurses can uphold the rights of patients, including the right to have quality safe treatment in a safe environment.
Assessment	<ul style="list-style-type: none"> Data are used to monitor for changes in conditions of patients. Data can show numerical values indicating safe or unsafe parameters for patient's body systems. 	<ul style="list-style-type: none"> Nurses continuously collect assessment data, interpret it, and intervene as appropriate for quality and safety of patient care. Data can change, and nurses need to monitor these changes to help prevent unsafe physical, emotional, or psychologic conditions for patients.
Clinical Decision Making	<ul style="list-style-type: none"> Nurses consider safety (both the patient's safety and the safety of other healthcare workers) in all phases of the nursing process, and while prioritizing patient needs. 	<ul style="list-style-type: none"> Assess patients for safety risks, factors that impact risks for falls, and ability to perform activities of daily living (ADLs) such as vision, hearing, mobility, and balance, and risk for or presence of abuse or neglect. Provide patient teaching regarding safety measures as appropriate based on assessment and evaluation of interventions.
Evidence-Based Practice	<ul style="list-style-type: none"> Evidence supports that many errors occurring in the healthcare setting can be avoided with improved performance of healthcare workers. Evidence supports that everyone in the healthcare environment, including patients, can improve quality and safety. 	<ul style="list-style-type: none"> Nurses can form partnerships with patients to work together for quality and safety of care. Evidence provides best practices for safety in nursing interventions. Improvements in quality and safety of patient-centered care contribute to best patient outcomes.
Quality Improvement	<ul style="list-style-type: none"> Improving quality of care for all patients involves ensuring and considering the safety of patients at all times when providing nursing care. 	<ul style="list-style-type: none"> Ensure a high quality of care in all interactions with patients. Resolve any safety concerns in the patient's immediate bed area. Ensure that the correct patient is receiving the correct type and amount of medication. Follow safety and procedural guidelines for patient care.

and speech patterns, mobility, eye contact, general appearance, balance, and other data. Some assessment data observed may need to be explored with the patient verbally. Common safety risk assessment data from the patient or family member during the interview include:

- Ability to communicate
- Ability to provide self-care
- Cognitive ability
- Memory deficiencies
- Bowel and bladder elimination and control
- Susceptibility to falls or any other safety risks
- Visual or other sensory deficiencies
- Mobility deficiencies

- Use of assistive devices
- Presence of Foley catheter, PEG tube, colostomy, or tracheostomy
- Skin integrity
- Vulnerability to injury
- Nutritional status
- Developmental considerations.

Teaching patients protective measures to reduce their vulnerability for safety issues in a healthcare facility, home setting, or community setting can help keep patients engaged in their nursing plan of care. See the feature on Patient Teaching: Patient Practices That Promote Safety in Healthcare Settings.

TABLE 51–1 Health Promotion Practices

Practice	Actions
Be physically active at any age to achieve health benefits as abilities and conditions allow.	<ul style="list-style-type: none"> ■ Make exercise a part of every day ■ Do effective exercising for long-term health benefits ■ Ongoing daily activity will increase energy ■ Physical activities can relieve stress
Use protection against injuries and accidents with appropriate safety gear and sports equipment; do activities in safe environments; choose appropriate activities to do; and follow rules for safety.	<ul style="list-style-type: none"> ■ Use gear such as helmets, mouth guards, knee and elbow pads, skin guards, padding, and protective eyewear as appropriate ■ Use well-lit populated sidewalks, supportive shoes, and stay hydrated ■ Follow game rules and fair play ■ Avoid risk areas ■ Check with healthcare provider before beginning new physical activities
Be smoke-free and avoid secondhand smoke.	<ul style="list-style-type: none"> ■ Participate in a cessation program ■ Avoid secondhand smoke areas ■ Health risks of respiratory and cardiovascular diseases are decreased
Motor vehicle safety.	<ul style="list-style-type: none"> ■ Follow guidelines for infant/child car seats ■ Don't be distracted by talking on a cell phone or texting; stay focused ■ Wear safety seat belts ■ Follow laws and road rules ■ Avoid aggressive drivers ■ Avoid driving when tired or sleepy
Eat appropriate diet and drink suitable beverages in moderation.	<ul style="list-style-type: none"> ■ Decrease portion sizes ■ Increase vegetable and fruit portions ■ Limit fats, sugar, and salt ■ Use low-fat dairy products
Include doing activities that are fun and relaxing.	<ul style="list-style-type: none"> ■ Do hobbies that stretch the mind and body ■ Practice stress management techniques
Maintain healthy weight.	<ul style="list-style-type: none"> ■ Minimize eating processed foods and fast foods ■ Eat an assortment of fruits, vegetables, and meats ■ Decrease obesity, currently found in all ages
Be smart about health promotion.	<ul style="list-style-type: none"> ■ Increase knowledge through online courses, attending training programs, and learning from others ■ Become empowered to make healthy choices ■ Avoid risk behaviors that can develop into chronic diseases such as smoking, poor eating habits, lack of physical activity, high stress environments, and low air quality
Attend local health fairs; participate in health screenings for eyesight, hearing, bone density, blood pressure, and blood glucose, and other community health activities.	<ul style="list-style-type: none"> ■ Periodic measurements can be used to look at health trends and changes in the body ■ Activity levels can show trends in mobility and flexibility
Allow time to de-stress.	<ul style="list-style-type: none"> ■ Disconnect from emails and phones for short periods to reduce stress ■ Take a short walk around workplace or home settings
Monitor personal health status.	<ul style="list-style-type: none"> ■ See a healthcare provider annually ■ Take medications as prescribed ■ Have immunizations recommended for specific age group
Allow for enough restful sleep.	<ul style="list-style-type: none"> ■ Have bedtime rituals to prepare the body to sleep ■ Follow routines of sleep habits
Have protection against temperature variances while inside or outside.	<ul style="list-style-type: none"> ■ Wear appropriate clothing ■ Use sunscreen to protect skin ■ Avoid long periods of time in temperature extremes ■ Control thermostats to maintain comfort ■ Use safe heating and cooling equipment ■ Use carbon monoxide alarms when inside of home

Patient Teaching

Patient Practices That Promote Safety in Healthcare Settings

Patients are at a higher risk for acquiring a healthcare-associated infection or injury because of the quality of safety in some healthcare settings. By following the steps below, patients can help make healthcare safer and help prevent healthcare-associated infections and injuries.

1. Have annual eye exams and update eyeglasses to maximize vision.
2. Exercise regularly to improve balance, joint mobility, and leg strength.
3. Eat a variety of nutrients and protein; drink adequate amount of water.
4. Follow directions for medications prescribed.
5. Wash hands appropriately as needed.
6. Know your body so that you notice changes in it.
7. Get vaccinations as prescribed for age group.
8. Use assistive walking aids as prescribed.
9. Maintain hygiene and self-care as able.
10. Recognize limitations of ability.

Source: From Centers for Disease Control and Prevention. (2013a). Patient safety: Ten things you can do to be a safe patient. *The National Institute for Occupational Safety and Health (NIOSH)*. Retrieved from <http://www.cdc.gov/Features/PatientSafety/>.

Physical Examination

Nurses are continuously observing patients, monitoring for unsafe changes in conditions, and making decisions about appropriate responses. For example, a nurse walks into a patient's room and assesses a patient with diabetes who is confused, agitated, and has a respiratory rate of 28 with a sweet odor to the breath. The nurse notices several candy wrappers on the bedside table. Based on this assessment data, the nurse quickly has a glucometer check done and finds the patient's blood glucose reading to be consistently 308 after two checks. The patient has changed from a safe blood glucose level to an unsafe increased level outside of normal range for this patient. Intervention is required.

There are four acute changes in condition that nurses must investigate to determine appropriate interventions and urgency in responding to them:

- **Cognitive changes**, such as decreased level of consciousness, change in memory, change in mood, difficulty thinking, and acute confusion.
- **Physical changes**, such as changes in vital signs, change in oxygen saturation, change in skin color, change in appearance of an incision, onset of diaphoresis, seizure activity, and an onset of pain.
- **Functional changes**, such as respiratory distress, change in mobility, onset of slurred speech, weakness of an extremity, numbness of extremity, and acute function deficit.
- **Behavioral changes**, such as inappropriate movements, disorientation to time and place, hallucinating, depression, and wandering (American Medical Directors Association [AMDA], 2015).

For example, changes in sputum color from clear to yellow, consistency from watery to tenacious, and amount from small to copious will influence the quality and safety of the patient's airway, so intervention is needed. Another example would be the older adult who develops acute slurring of speech, inability to move an arm, drooling, and inability to talk coherently, and has facial drooping on one side of the face, indicating a neurologic situation that needs immediate intervention for the safety of the patient.

Independent Interventions

Everyone, including healthcare workers, patients, families, and visitors, must assertively perform safety behaviors to prevent injuries, accidents, infections, and errors in all healthcare environments. In all settings, policies and procedures such as standard precautions assist nurses and other healthcare providers in ensuring the safety of the environment.

Standard Precautions

Standard precautions incorporate those guidelines previously referred to as universal precautions and body substance isolation (BSI). Standard precautions include measures such as the use of proper hand hygiene, protective equipment, and safe injection practices and the effective management of potentially contaminated surfaces or equipment. The transfer of infectious agents between nurses and patients is a serious safety concern to be addressed (see the module on Infection for further information).

Latex Exposure

Latex precautions are of particular importance to nurses, because products containing latex are common in the healthcare industry. Latex gloves, blood pressure cuffs, IV tubes, bandages, syringes, and catheters are among some of the common devices found in medical settings that can contain latex. Exposure to latex can trigger a latex allergy, which can become a serious problem for nurses, patients, and others. Symptoms may begin as itching, burning, redness, and swelling of the hands and fingers when latex gloves are worn or contact with other latex equipment or supplies occurs. Symptoms may become more severe, leading to asthma or anaphylaxis. Over a period of time, exposure to latex can develop into occupational asthma (AHRQ, 2008).

A number of precautions can be employed to avoid latex exposure for both healthcare workers and patients. Hypoallergenic (and specifically latex-free) and powderless gloves are helpful in preventing exposure. Not all hypoallergenic gloves are latex-free, so this should be ensured if an allergy or sensitivity is indicated. The powder from gloves can absorb the latex and then spread it when the gloves are removed; this can then release the allergen into the air, potentially affecting those with a severe sensitivity. Hand washing after taking off gloves is extremely important in preventing exposure to others.

Chemical Exposure

Exposure to hazardous and toxic substances is of paramount concern in the healthcare environment. Many chemicals found in this setting can be dangerous, including cleaning

Evidence-Based Practice

The World Health Organization (WHO) Hand Hygiene and Control of the 2015 Ebola Outbreak

Problem

Hand hygiene among healthcare providers was highlighted during the 2014–2015 West African Ebola outbreak as a cost-effective safety practice in the prevention and control of healthcare-associated infections (HAIs). Ebola virus disease (EVD) is a serious and often fatal disease that is spread through person-to-person transmission. This latest outbreak involved multiple countries and included people living in cities as well as rural villages. The number of cases and deaths during this EVD outbreak was higher than that for all other EVD outbreaks in the past combined. The West Africa outbreak was declared a Public Health Emergency of International Concern by WHO (**Figure 51–2** »).

Many materials and tools developed by the WHO were used in the response and recovery of the areas involved in this outbreak. The people in the communities of these countries were brought onboard by making hand hygiene resources available at public places such as banks, churches, and schools. Public service announcements were developed to inform people of the value of hand hygiene in controlling the transmission of this infectious disease.

Source: Centers for Disease Control and Prevention (CDC).

Figure 51–2 » Hand hygiene played an important role in controlling the 2015 Ebola outbreak. People had to be taught proper hand hygiene techniques that would help control this contagious disease.

Sources: World Health Organization. (2015a). *Clean care is safer care. Testing the WHO Guidelines on hand hygiene in healthcare in eight pilot sites worldwide*. Retrieved from http://www.who.int/gpsc/country_work/pilot_sites/introduction/en/; World Health Organization. (2015b). *Clean care is safer care. Hand hygiene in the control of Ebola and health system strengthening*. Retrieved from http://www.who.int/gpsc/hand-hygiene_ebola/en/; World Health Organization. (2015c). *Ebola virus disease. Fact sheet no. 103*. Retrieved from <http://www.who.int/mediacentre/factsheets/fs103/en/#>.

Evidence

To reduce the spread of infection from pathogenic microorganisms and prevent HAIs, global initiatives from WHO are implemented. WHO works with different levels of development and cultural environments around the world promoting hand hygiene as an effective solution. In 2004, WHO developed *Guidelines on Hand Hygiene in Healthcare*, an assortment of evidence reviewed and organized into documents.

Two years later, WHO launched a *Clean Care Is Safer Care* campaign. In 2006–2008 these strategies were used during a 2-year field test pilot program across six WHO regions. The project was to collect data and test the data for the reliability, validity, and sustainability of the guidelines to improve safety. Evidence determined that there was:

- Improved hand hygiene compliance found in all professional categories
- Increased knowledge of the importance of hand hygiene in preventing HAIs
- An enhanced culture of safety in healthcare facilities
- Scientific evidence that supported WHO hand hygiene strategies as a successful model for preventing HAIs (WHO, 2015a).

Implications

When this outbreak ended, the major African countries involved declared support to continue addressing HAIs with preventive actions, including improved hand hygiene among healthcare providers. Improvements in hand hygiene compliance for healthcare providers will support continued sustainability and prevention of HAIs. Conversations and actions addressing safety of water, sanitation, and waste management will also lessen the incidence of HAIs.

To continue to improve patient safety and prevent HAIs, the WHO Guidelines and Toolkit are kept current through organized reviews of scientific data and published studies about HAIs around the world. For example, the WHO *Multimodel Hand Hygiene Improvement Strategy* tool is used to implement change in safety practices of hand hygiene. Cleaning hands at the right times and in the right way, actions of simple hand hygiene, can make the difference (WHO, 2015b).

Critical Thinking Application

1. To reinforce the importance of hand hygiene to others, what can nurses do? Who can they teach hand hygiene practices to in the healthcare setting?
2. How does hand hygiene compliance change the number of HAIs that occur in the healthcare setting? Who needs to participate in this safety prevention behavior?

supplies, disinfectants, paints, and certain forms of air pollutants. To reduce hazardous exposures, healthcare facilities are using safer alternatives that are now available. Product solutions can not only be safe in the work environment, but also support a safer environment. One initiative to reduce environmental hazards for hospitals is *Go Green*, which advocates disposing of medical waste in an environmentally

friendly way following regulations developed by OSHA. Improved green safety products that are eco-friendly and reliable are now available (National Safety Council [NSC], 2014).

» **Stay Current:** For more information on hospitals going green, visit <http://www.healthcarebusinesstech.com/going-green-hospital/>.

Collaborative Efforts

Many local organizations in addition to international, federal, and state agencies collaborate to support quality health, safety, and cost efficiency initiatives in healthcare. Collaborative community initiatives may be started by community members in response to a serious, community-wide health issue. They may start through state-funded or federally funded initiatives that begin in response to larger statewide or nationally recognized health issues and that provide

funding at the community level to address these issues. Although national healthcare safety initiatives vary in approach, in general they support collaboration of government agencies, healthcare facilities, and people who work in healthcare to have safe healthy work environments and to provide patients safe quality care for best patient outcomes. **Table 51-2** » lists a number of current safety initiatives.

Even with safety initiatives in place, injuries, accidents, and errors can still happen in healthcare facilities, homes, and

TABLE 51-2 Safety Initiatives

Organization	Intent	Contributions
AHRQ, U.S. Department of Health & Human Services	Produce evidence that supports healthcare safety, make it more available, have a higher quality, be equitable, and cost effective while reducing medical errors and improving patient safety.	<ul style="list-style-type: none"> ■ <i>Patient Safety and Quality: An Evidence-Based Handbook for Nurses</i> (2008), developed with the Robert Wood Johnson Foundation. http://www.ncbi.nlm.nih.gov/books/NBK2651/ ■ For other AHRQ publications and products: http://www.ahrq.gov/research/publications/index.html

communities. Initiatives, policies and mandates need to include the “people factor” to be successful. Everyone in healthcare wants to have a safe and healthy environment, and it takes everyone to make it happen by creating a culture of safety. A **safety culture** is a general feeling of shared attitudes, values, practices, and beliefs that result in behaviors and feelings of responsibility for safety in all daily routines (OSHA, 2015). Safety awareness is heightened throughout all areas.

Organizations and employees working together can build and maintain a safety culture, resulting in improved safety and quality of care for patients and fewer unsafe and unhealthy conditions for themselves. This means anyone can report unsafe conditions or behaviors and help find solutions to correct them.

A safety culture is a blame-free environment. With a focus on systems, individuals can report errors or near misses without fearing reprimand or punishment. Some healthcare facilities have created a “just culture” that looks not only at systems but also at how they may have contributed to an individual’s unsafe action (see the module on Quality Improvement for further information). Everyone in a healthcare safety culture is aware of the importance of how they work and is determined to consistently do their work correctly and safely. They all are involved with the planning, implementation, and evaluation of initiatives for safety and health concerns, actively working together to find methods for quality improvement.

Some things healthcare facilities can do to support safety initiatives are to:

1. Make necessary resources available
2. Include all levels of employees in committees making decisions about initiatives
3. Celebrate improvements when quality programs are implemented
4. Do management walk-arounds to support staff
5. Offer periodic safety training
6. Share successes in improved patient outcomes and safety goals attained.

One way to measure the success of safety cultures is to use a validated survey. Two examples of these surveys are the *AHRQ’s Patient Safety Culture Surveys* and the *Safety Attitudes Questionnaire* (AHRQ, 2014). For those who work in a safety

culture environment, there can be improved job satisfaction for protecting patients and others from safety and health hazards. Safety hazards and health risks can also be minimized for the employees in this environment, resulting in a decrease in injuries, accidents, illnesses, and errors. Healthcare is about those who provide the care and those who receive the care; healthcare facilities need safety and health protection for everyone.

In 2005, the Robert Wood Johnson Foundation funded a group of distinguished nursing leaders and faculty to use the Institute of Medicine’s healthcare clinician competencies from the *Crossing the Quality Chasm: A New Health System for the 21st Century* report to develop core nursing competencies. These nursing competencies, called **Quality and Safety Education for Nurses (QSEN)**, would better prepare nursing students with practical experience in providing safer more effective care. They were further defined with specific knowledge, skills, and attitudes (KSAs) necessary to provide better quality and safety in healthcare settings (see **Table 51-3** >>) (QSEN, 2014a, 2014b, 2014c).

The Joint Commission began its **National Patient Safety Goals (NPSG)** program in 2002 to help accredited organizations deal with specific topics on patient safety. NPSGs are developed and revised by the Patient Safety Advisory Group (PSAG), which is a panel of nurses, physicians, pharmacists, risk managers, engineers, and other professionals who have expertise related to patient safety issues within healthcare organizations. PSAG determines topics for NPSGs by analyzing safety concerns and evaluating which ones will have the maximum impact and usefulness for the minimum cost. Input is also solicited from practitioners, provider organizations, purchasers, consumer groups, and others. NPSGs are updated annually. Each goal is accompanied by elements of performance that The Joint Commission identifies as necessary to meet the goal. For example, among the NPSGs required for hospital accreditation in 2016 is the *goal* that agencies identify patients correctly, which is accompanied by two *elements of performance*, which relate to (1) consistently using two methods of identifying the patient, and (2) ensuring that patients receiving blood transfusions are correctly identified prior to transfusion (The Joint Commission, 2016).

>> **Stay Current:** For the most current National Patient Safety Goals, go to the website of The Joint Commission: www.jointcommission.org.

TABLE 15-3 QSEN Nursing Competencies

QSEN Competency	Definition
Patient-Centered Care	Patients are partners in their care, and thus their perspectives, beliefs, and culture need to be taken into consideration during their care.
Quality Improvement	Adverse events must be monitored and reported so they can be tools for learning in similar situations in the future and catalysts for improvements in quality and safety.
Evidence-Based Practice	Medicine is evolving and changing every day, and thus current medical findings must be monitored for the possibility of improved care.
Teamwork and Collaboration	Because treatment sometimes involves multiple departments and 24-hour care, teamwork across departments and shifts is necessary for optimal care.
Informatics	As information technology becomes further integrated into medicine, nurses’ input is an essential part of the design process.
Safety	Activities such as knowledge sharing and error reporting must be taken seriously to help improve safety.

REVIEW The Concept of Safety

RELATE Link the Concepts

Linking the concept of safety with the concept of tissue integrity:

1. Describe safety precautions that can be taken to prevent skin breakdown.
2. The nurse is caring for a patient with third-degree burns over 50% of his body. Identify three nursing interventions that promote safety while also facilitating the patient's healing and providing comfort.

Linking the concept of safety with the concept of ethics:

3. Explain the ethical considerations in a scenario in which a patient has been given the wrong medication, but with no adverse effects. Discuss the patient's right to be informed about the mistake. How should the nurse who committed the error handle this situation?
4. A surgeon nearly performed the wrong surgery on a patient, but the mistake was caught before a surgical incision was made. The correct surgery was performed, but the surgeon has not reported the original error. Does this scenario require submitting a report? Describe the dilemma faced by the surgical team in this scenario.
5. Describe the ethical dilemma associated with the use of restraints and respect for a patient's autonomy. Under what circumstances are restraints indicated for use in a patient's care?

Linking the concept of safety with the concept of oxygenation:

6. What are some teaching points the nurse should discuss with a chronic obstructive pulmonary disease (COPD) patient who keeps changing his oxygen settings?
7. Describe safety considerations when beginning supplemental oxygen on an asthmatic patient.

Linking the concept of safety with the concept of cognition:

8. Contrast differences in etiology between acute confusion and chronic confusion.
9. Plan safety interventions for the patient with early signs of dementia.

Linking the concept of safety with the concept of caring interventions:

10. Explain why safety when doing invasive interventions such as inserting a Foley catheter is a priority.
11. Relate the safety reasons for using evidence-based instead of traditional methodology for performing caring interventions.

READY Go to Volume 3: Clinical Nursing Skills

REFLECT Apply Your Knowledge

A 72-year-old patient is admitted to the hospital for treatment of severe dehydration secondary to advanced and untreated urinary tract infection. She is normally very independent and does not often like to ask for help, particularly when she needs to use the bathroom. The patient's nurse recognizes the patient's desire for independence, but also realizes that she is at a heightened risk for falling because of the infection and corresponding dehydration-related signs and symptoms, including weakness and dizziness. The nurse talks to the patient about the risk of falling, as well as the possible injuries that could occur if she were to fall. He does not want the patient to lose her sense of independence, so he rearranges the chairs in the room so she has a clear line from the bed to the bathroom. The nurse then discusses the need for the patient to wear socks and/or slippers with gripper bottoms when she walks to the bathroom to further prevent falling. Together the nurse and patient develop a plan of care that respects the patient's needs and also works to ensure her overall safety.

1. Describe three reasons why the patient's situation represents an advanced risk for falling.
2. Explain the nurse's approach to the situation described above. What communication and collaboration efforts does he employ?
3. Evaluate the nurse's recommendations for the patient. Are these recommendations appropriate? Why or why not?
4. Would the situation above be any different if the patient were 30 years old? If so, how? Explain your answer.

Exemplar 51.A Health Promotion and Injury Prevention Across the Lifespan

Exemplar Learning Outcomes

51.A Analyze health promotion and injury prevention across the lifespan as they relate to safety.

- Summarize the risks for injury, health promotion, and injury prevention in the perinatal period and for infants.
- Outline the risks for injury, health promotion, and injury prevention for toddlers and preschoolers.

- Contrast safety considerations in healthcare settings for patients across the lifespan.
- Summarize the risks for injury, health promotion, and injury prevention for young and middle-aged adults.
- Outline the risks for injury, health promotion, and injury prevention for older adults.
- Plan nursing interventions for health promotion and injury prevention for individuals with special needs.

Exemplar Key Terms

Birth defects, 2882
Fetal mortality, 2882

Functional decline, 2888
Individuals with special needs, 2889
Screening tests, 2882

Overview

Health promotion includes activities that increase well-being and enhance health, such as appropriate nutrition, oral health, physical activity, and mental health. To be more effective, nurses can build partnerships with families so healthcare visits include all family members present to participate in discussions about questions or health topics they may have, support family strengths, improve communication, and work together as a team. These family visits also provide opportunities for nurses to observe each family member; note family dynamics; assess nutrition, growth and development, mental and spiritual health; and promote injury prevention strategies for everyone.

Illness prevention strategies focus mainly on the prevention of disease. **Screening tests** are procedures used to detect the possible presence of health conditions before symptoms are apparent. Vision and hearing screening tests are frequently conducted when children begin attending school. Most screening tests are not diagnostic by themselves but are followed by further diagnostic tests if the screening result is positive. Once a screening test identifies the existence of a health condition, intervention can begin.

Health promotion and safety needs vary across the lifespan, with parents taking care of the needs of infants and young children, school-age children adolescents accepting more responsibility for their health, adults bearing complete responsibility for their health, and older adults often sharing responsibility with their adult children.

Safety in the Perinatal Period and for Infants

The Perinatal Period

A total of 23,595 fetal deaths at 20 weeks' gestation or more were reported in the United States in 2013. This translates to a mortality rate of 5.96 fetal deaths per 1000 live births. These numbers compared to the previous year show that there were more fetal deaths than infant deaths occurring in the United States. Fetal mortality rates were highest for teenagers, women aged 36 and over, unmarried women, and women with multiple pregnancies (CDC, 2015a). **Fetal mortality** is the intrauterine death of a fetus at any gestational age. The majority of fetal deaths occur early in pregnancy. The following risk factors for perinatal mortality (the time immediately before or just after birth) have been identified: maternal obesity, smoking during pregnancy, severe hypertension or diabetes, congenital anomalies, infections, placental and cord problems, and intrauterine growth retardation (CDC, 2015a).

Early and regular prenatal care can result in having a healthy pregnancy, which promotes a healthy birth. Some women will make changes in their health routines before they actually are pregnant to further promote a healthy pregnancy such as to stop smoking, attain a healthy weight,

and learn about familial health conditions. Genetic counseling can help people learn more about genetic health conditions and the chances of having a child with a gene-related condition. Prenatal care can help prevent complications and provide women information about things they can do to protect the fetus and ensure fetal health and development. The healthcare provider can monitor the mother's health and development of the fetus during the pregnancy. Some prenatal risks are controllable, such as cessation of smoking, drinking alcohol, or taking certain medications during pregnancy, and some are not, such as first-time pregnancy after the age of 35 or occurrence of a familial physical abnormality. Having prenatal care as soon as pregnancy is determined by a healthcare provider can help increase incidence of having a healthy baby. See the exemplar on Antepartum Care in the module on Reproduction for more information.

Infants

Birth defects are common occurrences in the United States. Nearly 120,000 babies are affected by birth defects each year.

Birth defects are changes in physical structure present at birth that can affect many parts of the body, such as the heart, foot, or palate. Depending on the severity and location of the birth defect, expected lifespan may or may not be affected (CDC, 2015b). Examples of birth defects include congenital heart defects, Down syndrome, spina bifida, and lower limb reduction defects. Birth weight is a good predictor of the survival and healthy development of a newborn. Newborns are screened while still in the hospital for critical birth defects that cannot be seen, such as hearing loss, heart defects, hemoglobin disorders, hormonal insufficiency, cystic fibrosis, or inability to process certain nutrients. Types of screening and how many conditions to look for are determined by each state. See the exemplar on Newborn Care in the module on Reproduction for more information.

Congenital anomalies and short gestation continue to be common causes of mortality as the neonate, or newborn, matures into an infant. Sudden infant death syndrome (SIDS) is the leading cause of death among infants between 1 and 12 months (U.S. National Library of Medicine, 2015). Complications during delivery and unintentional injuries also can result in infant death, with the most common unintentional injuries resulting from suffocation, often as a result of co-sleeping (CDC, 2013b). See the exemplar on Sudden Infant Death Syndrome in the module on Oxygenation for more information.

Maltreatment of children, abuse or neglect, causes injuries or deaths each year. In 2012, 27% of victims were younger than 3 years, 20% were age 3–5 years, and children younger than 1 year had the highest rate of victimization, 21.9 per 1000 children. Of the child victims, 78% were victims of neglect; 18% of physical abuse; 9% of sexual abuse; and 11% of emotional and threatened abuse or lack of supervision. An estimated 1640 children died from child maltreatment, with 70% of those deaths occurring among children

Source: ArtMarie/iStock/Getty Images.

Figure 51-3 » An infant's head circumference is measured at every well-child visit.

younger than age 3 (CDC, 2014a). See the exemplar on Abuse in the module on Trauma for more information.

Because of their immature musculoskeletal systems and relative immobility, infants are also susceptible to a number of unintentional injuries. Falls accounted for nearly 50% of these injuries, and because of their soft heads, infants are particularly susceptible to traumatic brain injury. Another 14% were unintentionally struck by or against something, and an additional 7% of injuries were due to bites or stings (CDC, 2013b).

Nursing Implications

Newborns and infants are measured for growth and developmental trends at each visit to the healthcare provider. Measurements of their length, weight, and head circumference can be compared with weight gain and growth percentile ranges (**Figure 51-3** »). Observing the newborn and infant for developmental milestones such as lifting the head, smiling, rolling front to back, sitting without support, playing with toys, and imitating sounds readily provides assessment data for trending as the infant grows older. First-time parents may need more teaching and demonstrations of

Patient Teaching

When to Contact the Infant's Healthcare Provider

Encourage parents to call the healthcare provider any time they have a question. Teach parents to call the pediatrician's office for the following situations:

- Seizure activity
- Temperature of 100.4°F or above
- Skin change in color and presence of petechiae or skin rash
- Refusal to eat or drink
- Change in behavior or activity unusual for infant
- Vomiting
- Diarrhea
- Decreased urine
- Respiratory infection unusual for infant

Source: From Centers for Disease Control and Prevention (CDC). (2013c). *Leading causes of death reports, 1999–2010*. Retrieved from http://webappa.cdc.gov/sasweb/ncipc/leadcaus10_us.html.

newborn care to be comfortable and safe in caring for their new infant at home. See **Table 51-4** » for strategies for promoting infant safety. Teach parents when to contact the infant's healthcare provider as outlined in the Patient Teaching feature.

» **Stay Current:** The CDC provides information for current recommended immunization schedules for children aged 0 through 18 years old. <http://www.cdc.gov/vaccines/schedules/downloads/child/0-18yrs-child-combined-schedule.pdf>.

Safety for Toddlers and Preschoolers

Among all ages of children, unintentional injuries are the leading cause of death. Risks related to unintentional injury vary by age; for example, the toddler's mobility increases his risk for drowning in a swimming pool, whereas the infant is more likely to drown in the bathtub or a bucket, and

TABLE 51-4 Strategies for Promoting Infant Safety

Strategies for Injury Prevention	Strategies for Disease Prevention
<ul style="list-style-type: none"> ■ Swaddle newborns so they feel secure; allow free movement of arms and hands ■ Position infants on the back during sleep periods; put infants to sleep in warm clothing on a firm mattress in a crib or bassinet; do not place blankets, bumpers, pillows, or toys in the crib ■ Position infant on the abdomen during supervised play periods ■ Encourage appropriate toys such as crib mobile, soft toys, musical toys ■ Create an environment that is infant-centered, allowing for learning, thinking, responding, and solving problems ■ Know choking and CPR procedures for an infant 	<ul style="list-style-type: none"> ■ Other considerations: motor vehicle safety restraints, shaken baby syndrome, bed-sharing, drowning, suffocation, burns, falls, pet safety, fire safety, poisoning, and gun safety ■ Avoid secondhand smoke exposure ■ Reduce risks for sudden infant death syndrome ■ Use proper hand hygiene before handling infant ■ Limit exposure to large crowds, especially in cold season ■ Begin oral care by gently wiping gums with soft gauze 1–2 times a day ■ Vaccinate infant with routine immunizations such as hepatitis B, DTP, <i>Haemophilus influenzae</i> type b, inactivated poliovirus, pneumococcus, influenza, and rotavirus

Figure 51-4 » Toddlers are vulnerable to accidents as they try out new skills and explore the world.

bicycle accidents are more common among school-age children. Note that the risk for ingesting chemicals or medications is highest among toddlers, preschoolers, and school-age children. Patient education for parents and caregivers of children in these age group includes keeping all medications and chemicals out of reach.

Toddlers

Toddlers begin walking, exploring the world around them, testing limits, and playing with anything in reach (**Figure 51-4** »). Their small size and developing bones make them particularly vulnerable during motor vehicle crashes or when hit, pushed, or shaken. Drowning is of particular concern, particularly around swimming pools. The leading causes of death for this age group are accidents with unintentional injuries, and congenital malformations, deformations, and chromosomal abnormalities (CDC, 2015c). Toddlers also are at risk for injury or death due to fires or burns and suffocation. Another cause of death for young children occurs when they are left locked in parked motor vehicles.

SAFETY ALERT Even on a mild day (72°F), the temperature inside a closed car can escalate 30–40°F in an hour. Heat stroke may occur when the body temperature exceeds 104°F. Each year, an average of 38 children die in hot cars in the United States (Kids and Cars, 2016).

» **Stay Current:** For a list of safety tips and strategies parents and caregivers can use to prevent children from being locked in vehicles, visit the Kids and Cars website at <http://www.kidsandcars.org/heatstroke.html>.

Preschoolers

Preschool-age children are more mobile and coordinated than toddlers, yet not fully aware of the dangers that surround them. Although the number of injuries and fatalities are reduced compared to toddlers, the most common causes of injury and fatality in preschoolers are generally the same.

The leading cause of death for this age group is accidents with unintentional injuries, many by motor vehicle crashes. Appropriate car seat and booster seat usage and belt positioning can reduce the numbers of injuries and fatalities. Approximately 14% of preschooler fatalities related to unintentional injuries are caused by fires or burns, and over 6% by suffocation (CDC, 2013c).

Nursing Implications

Toddlers and preschoolers continue to be measured for growth and developmental trends. Measurements of their standing height, weight, and BMI are done and compared with height and weight percentile ranges. Children are monitored for development of fine and gross motor abilities, social behaviors and socialization with others, increased skill in language development, and temperament. Observing the toddler and preschooler for developmental milestones such as walking, drinking from a cup, feeding self, kicking a ball, drawing lines on paper, stating name, and building a tower of blocks provides assessment data for trending as the child grows older. Screen children for anemia, number and condition of teeth, signs of possible abuse such as bruising, and skin or gait problems. Teaching parents about risk factors associated with these age groups can help reduce the incidence of unintentional injuries. See **Table 51-5** » for strategies to teach parents for promoting safety for toddlers and preschoolers.

Safety for School-age Children and Adolescents

School-Age Children

Children age 5–10 are much more active than younger children and can play farther from home with less supervision. They are less dependent on their parents and move faster on foot and on bicycles, leading to more falls, accidents, and playground injuries. Unintentional injuries account for almost one third of deaths, of which more than 40% are caused by motor vehicle crashes. Nonfatal injuries mainly come from unintentional falls. In line with the increased activity of children this age, overexertion and bicycle accidents both accounted for 5% of injuries (CDC, 2013c).

Adolescents

Adolescents age 11–18 are exposed to a number of new risks. They are trying to develop their own identities apart from their parent(s), facing increasing peer pressure from all directions, receiving driver's licenses, and playing contact sports. They are most likely to start experimenting with drugs and alcohol in this age range. They are also experiencing emotional turmoil, leading to outward aggression and fighting, or internalizing and suicide. Now competing more seriously in sports and play, adolescents age 10–14 have the highest rate of injury during sports and play (**Figure 51-5** »).

Most deaths for this age group are due to unintentional injury from motor vehicle crashes, poisoning (with 80% of these due to drug exposure of some kind), and drowning. Suicides, which do not qualify as unintentional but which are preventable, account for a small percentage of adolescent deaths. Other unintentional nonfatal injuries are from

TABLE 51–5 Strategies for Promoting Safety for Toddlers and Preschoolers

Strategies for Injury Prevention	Strategies for Disease Prevention
<ul style="list-style-type: none"> ■ Help with food choices and eating patterns. Eat fewer fast foods and more fruits and vegetables ■ Provide physical activities that use large muscle groups ■ Help child learn about what is right and wrong, and rules that guide behaviors ■ Discipline the child for undesirable behaviors ■ Prevent air, water, or other toxic exposures ■ Prevent lead exposure in the home ■ Use appropriate harness straps or lap and shoulder belts for car safety ■ Other considerations: falls, drowning, poisoning, burns, motor vehicle crashes, pedestrian accidents 	<ul style="list-style-type: none"> ■ Avoid secondhand smoke exposure ■ Teach child to brush teeth; have scheduled dentist visits ■ Encourage adequate sleep and rest ■ Teach child safety around strangers ■ Be alert for electrical cords hanging down, water temperature higher than 120°F, sun exposure, and playing unsupervised ■ Teach child about hand washing, calling for help using the telephone ■ Vaccinate child with routine immunizations such as hepatitis B #3 in series and A, DTP, <i>Haemophilus influenzae</i> type b, inactivated poliovirus, pneumococcal, influenza, measles, mumps, rubella, varicella ■ Teach children about crossing streets, riding bicycles, playing in water safety, and avoiding fire hazards ■ Know choking and CPR procedures for a child

Figure 51–5 >> This teenage skateboarder is at risk for fractures and head injury because he is not wearing protective equipment.

unintentionally being struck by or against something, unintentional falls, overexertion, and as a motor vehicle occupant (CDC, 2013c).

Nursing Implications

School-age children continue to have their height, weight, and BMI monitored. Their bodies are refining muscular strength and coordination. They need encouragement to establish good health habits for nutrition, physical activity, and mental health, and to avoid tobacco, alcohol, and drugs. Children are learning decision-making, problem-solving skills, and refining skills with sports such as eye-hand coordination, agility, and speed. Their deciduous teeth are being replaced by permanent teeth. They are increasingly more active in after-school activities such as sports and clubs.

Continue observation for developmental milestones such as independence in bathroom and dressing activities, reading, developing hobbies, playing musical instrument, writing well, skill at computer use, developing self-esteem more with feelings of self-worth related to physical appearance and social interactions, developing body image of self, having prepuberty changes (girls may begin to menstruate), common mental disorders such as anxiety, worrying, fears, stress, sleep disorders, depression, and building relationships outside of family. This observation provides assessment data for trending as the child grows older. Screen for blood pressure, bruising, repeated infections, changes in school performance or behavior, medications being taken, and any integrative therapies used.

Parents need to adapt discipline methods to actions such as withholding privileges and using time-out; spanking and yelling should be avoided. School-age children can be taught risk factors and how to help reduce the incidence of unintentional injuries, such as by wearing a helmet when riding a bicycle. See **Table 51–6** >> for strategies for parents to promote safety for school-age children; also see the Patient Teaching feature on use of bicycle helmets.

TABLE 51–6 Strategies for Promoting Safety in School-Age Children

Strategies to Prevent Injury	Strategies to Prevent Disease
<ul style="list-style-type: none">■ Latchkey children who come home to an empty house after school need encouragement to remain safe, responsible, and have feelings of security■ Teach children about fire, firearms, water, and other safety hazards and what to do in emergencies■ Teach children about safety around interacting with strangers—accepting rides from them, chatting with them online, or talking with them on the phone■ Promote healthy sleep behaviors■ Use proper safety equipment to avoid sports injuries, especially from sports such as skateboarding, football, soccer, skiing, rollerblading, and motorcycle and ATV riding■ Teach children safe resources such as teachers, school counselors, and police or security■ Watch for signs of risky behaviors such as substance abuse, smoking, aggression and violence, eating disorders, and anxiety■ Other considerations: pedestrian or biking accidents, handling firearms unsupervised, burns from experiments with flames or toxic substances, assault from a stranger, and what to do when scared and alone in a public or private area	<ul style="list-style-type: none">■ Encourage independent food choices, including fruits and vegetables; suggest frequent snacks of nonfat and nonsugar choices■ Continue oral health with brushing, flossing, and dentist visits■ Teach children how to prevent diseases by washing their hands, avoiding respiratory infections, and avoiding causes of gastrointestinal illness■ Connect health with risk behaviors such as smoking, poor oral hygiene, low physical activity, having above-normal weight, and skin problems■ Limit television and video game time■ Continue with immunizations as needed

Sources: Ball, J. W., Bindler, R. C., Cowen, K., & Shaw, M. (2017). *Principles of pediatric nursing: Caring for children* (7th ed.). Hoboken, NJ: Pearson Education.; CDC. (2015c). Ten leading causes of death and injury. *Injury Prevention & Control: Data & Statistics (WISQARS™)*. Retrieved from <http://www.cdc.gov/injury/wisqars/leadingcauses.html>; CDC. (2015d). *Influenza vaccination information for health care workers*. Retrieved from <http://www.cdc.gov/flu/healthcareworkers.htm>.

When caring for adolescents, continue to monitor height, weight, and BMI. Observing the adolescent for developmental milestones provides assessment data for trending as the individual grows older. Self-concept continues to evolve; body changes may lead to decisions about sexual behaviors. Older adolescents should be asked if they are having sexual intercourse and, if so, if they are using protection against pregnancy and sexually transmitted infections. Ask about confusion with sexuality, sexual practices, and gay, lesbian, or bisexual activities. Their

relationships and friends are very important, and they will test limits of parents and engage in conflicts with them. School offers peer support and meaningful activities, but also causes stress, worry about grades, and violent or unsupportive school situations. Injuries are a major health hazard for this age group, so caregivers need to be made aware of risk factors and how to reduce the incidence of unintentional injuries to prevent them. See **Table 51–7** >> for strategies that parents can use to promote safety in adolescents.

Patient Teaching

Bicycle Safety

Children age 5–14 years have a high rate of nonfatal bicycle-related injuries. Helmets can reduce the number of head and brain injuries if worn correctly (**Figure 51–6** >>); unfortunately, they often are

Source: Mari/E+/Getty Images.

Figure 51–6 >> Wearing an age-appropriate, well-fitting helmet helps reduce the risk of head and brain injuries.

either not worn or worn incorrectly (too far back on the head) (CDC, 2015e).

Suggested interventions for reducing injuries and fatalities to bicyclists include:

- Wearing fluorescent clothing to be more visible from farther away
- Wearing retro-reflective clothing to be more visible at night
- Wearing age-appropriate helmets that are well maintained
- Adding lights on the bicycle or bicyclist such as front white lights and rear red lights
- Making sure the helmet is properly fitting; it should fit snugly all around with no spaces between the foam and the bicyclist's head
- Wearing helmet correctly: (1) the bottom of the pad inside the front of the helmet is one or two fingerwidths above the bicyclist's eyebrows, (2) the back of the helmet should not touch the top of the neck, (3) side straps should form a "V" shape under and slightly in front of the ears, (4) the chin strap should be centered under the bicyclist's chin and fit snugly, not moving in any direction.

TABLE 51–7 Strategies for Promoting Safety in Adolescents

Strategies to Prevent Injury	Strategies to Prevent Disease
<ul style="list-style-type: none"> ■ Encourage consumption of nutritional foods to support immune system, physical activity, and metabolism ■ Encourage adequate sleep ■ Encourage regular physical activity ■ Avoid high noise levels such as when listening to music through earbuds or headphones ■ Encourage oral health behaviors; be alert for ulcers or unusual growths in mouth, self-induced vomiting with anorexia or bulimia which harms tooth enamel, chewing tobacco resulting in oral ulcers, cancers, and certain sports that are higher risk for injuries, such as hockey and football ■ Observe for signs of depression such as changes in behavior, school performance, sleep, and appetite; sadness; poor concentration; feelings of worthlessness; thoughts of death or suicide ■ Observe for signs of substance abuse such as changes in behavior, school performance, sleep, and appetite, lack of responsibility, inability to set goals, hopelessness, multiple accidents ■ Teach and encourage safe driving behaviors ■ Other considerations: safety with four-wheelers, boats, jet skis, farm machinery, tools, drowning, sun exposure, fires, firearms, hearing problems from loud music, abuse 	<ul style="list-style-type: none"> ■ Seek medical attention for acne and skin infections ■ Seek medical treatment for anemia, monitor dietary choices, encourage rest periods ■ Encourage use of appropriate safety equipment to avoid sports overuse injuries, teach safety for flexibility and muscular limitations ■ Discuss bowel and bladder patterns and recognition of constipation and diarrhea, teach dietary choices to avoid bowel problems, teach importance of fluid intake to support bowel habits ■ Discuss aseptic technique needed for body piercing and tattooing to avoid infection, discuss decision-making that has long-range impacts later in life ■ Discuss wellness habits to help prevent fatigue, such as healthy eating, exercise activity, amount of sleep, and emotional support ■ Use sunscreen to avoid sunburn and risk for later skin lesions ■ Discuss and provide information about sexually transmitted infections such as HIV, herpes, syphilis, gonorrhea, hepatitis A, and the viruses that cause warts and herpes that can be transmitted through unprotected intercourse or oral sex; provide options to protect adolescents against acquiring these diseases and conditions ■ Discuss physical and emotional complications of eating disorders such as anorexia and bulimia; obtain counseling if needed ■ Discuss safety and protection if being abused or bullied by another individual, observe for signs of abuse, provide information about strategies to remain calm and protect oneself from altercations, provide safe adults to go to when needing assistance ■ Observe for signs and symptoms of substance abuse and provide medical help as needed, monitor for any drug paraphernalia or drugs, discuss addiction and safety implications of certain drugs in the body ■ Stress importance of cessation of smoking and use of nicotine products to avoid addiction and chronic health conditions ■ Common immunizations recommended: TD if last one >10 years ago, second measles-mumps-rubella, meningococcal vaccine recommended, human papillomavirus vaccine (3-dose series), annual influenza vaccine

Safety for Adults

Young Adults

Young adults, ages approximately 19–45, are generally striking out on their own, getting jobs, being educated, getting married, and having kids. However, this independent living means making their own choices and mistakes, some of which can lead to life-altering changes. Young adults die from unintentional injuries resulting from poisoning mostly by drugs, narcotics, medicines, or biological agents; motor vehicle crashes; malignant cancers; heart disease; suicide; and homicides (**Figure 51–7**) (CDC, 2013c). Sources of nonfatal injuries include unintentional falls, inadvertent overexertion, being accidentally struck by or against something, and unintentional cuts or piercing wounds. Overexertion can be a particular concern among recreational athletes, who may be at greater risk for dehydration, exposure-related illness, or sports-related injury.

Middle Adults

Middle adults, ages 46–65, are beginning to look toward retirement. Middle adults have started to slow down, probably becoming less active and developing some chronic health problems as the healing process slows. For the first time, unintentional injuries are not the leading cause of death. Instead, malignant cancers account for one third of deaths. Heart disease is the second leading cause of death, due to age and obesity. Unintentional injuries that result in

death are caused by poisoning, mostly from drugs, narcotics, medicines, or biological agents. A little over one quarter of fatalities are due to motor vehicle traffic and falls. Suicides in this age group represent a small percentage of deaths (CDC, 2013c). For the middle adults who experience injuries that do not end in fatality, the majority of these injuries are due to unintentional falls, and the others due to overexertion, accidental injury due to being hit by or against something, and motor vehicle crashes (CDC, 2013b).

Strategies for promoting safety for adults are shown in **Table 51–8** >>.

>> **Stay Current:** The CDC provides information for current recommended immunization schedules for adults: <http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-schedule-easy-read.pdf>.

Safety for Older Adults

About 65% of older adults retire by the time they turn 65. Of those still working past 65, more than a third work part time (Sightings, 2014). As older adults continue to age, living independently can become challenging for those experiencing chronic illnesses that impact cognition or mobility. Chronic diseases such as heart disease, malignant cancers, cerebrovascular illness (stroke), chronic respiratory disease, Alzheimer disease, and diabetes are common causes of fatality in this age group. The highest cause of death from unintentional injury is falls, then motor vehicle crashes, suffocation, poisoning, and fire (CDC, 2013c).

Older adults in assisted living facilities or living in their own homes need to take steps to actively prevent functional decline. **Functional decline** is a reduction in the quality of or ability for physical or cognitive function. It may only take a couple of days to begin to manifest through changes such as diminished ability to complete ADLs, impaired mobility, decreased musculoskeletal strength, and reduced physical endurance (Government of South Australia, 2016).

By reducing the risk of functional decline, nurses and independent older adults can help prevent complications of this condition, such as pressure injuries, delirium and depression, decreased mobility, loss of independence, and incontinence. Reducing functional decline may be helped by encouraging older adults to keep mobile, active, and engaged in ADLs as physically and cognitively able. Precautionary measures need to be implemented for the prevention of injury in the elderly with impaired mobility or altered cognitive function. Reorientation to the patient’s room, how to get to a restroom, and how to call for help will also help reduce functional decline when in an assisted living facility.

Some communities have daycare centers with staff trained to work with older adults. Another community-based resource for the elderly is a senior center that offers a variety of activities for the elderly to participate in and socialize with others their age (**Figure 51–8** >>). There are also many federal, state, local, and private advocacy organizations dedicated to providing services for the elderly. Oral care remains important to prevent periodontal diseases such as oral and pharyngeal cancers. See the Patient Teaching feature for factors affecting oral health and **Table 51–9** >> for strategies to promote safety in older adults who live in the community.

Safety for Individuals with Special Needs

Safety is focused on the developmental level and physical capabilities of individuals. Strategies to prevent unintentional injuries can be adapted for those with special needs.

Figure 51–8 >> Senior centers offer companionship and activities for older adults.

Patient Teaching

Oral Health for Older Adults

Older adults are at risk for poor oral health for a number of reasons. Approximately 25% of older adults no longer have their natural teeth, which may lead them to choose soft, easily chewed foods and avoid fresh fruits and vegetables (CDC, 2013d). Older adults face increasing severity of periodontal disease. Oral and pharyngeal cancers, primarily diagnosed in older adults, have poor prognoses. Those with the poorest oral health are those who are economically disadvantaged, do not have dental insurance, and are members of ethnic minorities. Those who are disabled, bedbound, homebound, or institutionalized have higher risk of poor oral health (CDC, 2013d).

Another factor that contributes to poor oral health is the high number of prescription and over-the-counter drugs older adults take that cause a dry mouth. Saliva contains antimicrobial components as well as minerals that help rebuild tooth enamel attacked by decay-causing bacteria, so when saliva production is decreased, the risk for oral disease is increased. There are also chronic neurologic or musculoskeletal conditions such as Alzheimer disease and stroke that limit the ability of older adults to perform oral health self-care.

Nurses should encourage older adults and/or those assisting them to:

- Periodically assess the mouth for changes in appearance, tenderness of gums, sensitivity of teeth, presence of saliva,

cracked skin areas, ulcerations, or pain, and report anything unusual to their healthcare provider.

- Observe for bleeding gums when brushing natural teeth, red swollen gums, and chronic bad taste or bad breath, as these may indicate gum disease.
- Remember to stay hydrated to maintain good salivary flow. Dry mouth may occur as a side effect of certain medications prescribed.
- Notice if the corners of the mouth and the lips are dry and cracked. A lubricant can be applied as needed to prevent problems with skin integrity.
- Clean any dentures daily and rinse them after every meal. Ensure food particles and other debris are removed after each meal.
- Brush teeth every day, as able, and after every meal, or have assistance with oral care.
- Have oral hygiene materials available, such as toothbrushes, toothpaste, denture cleaning products, and mouthwash.
- Prevent aspiration with positioning and assistance as needed during mouth care.
- Schedule annual appointments with the dentist.

Individuals with special needs refers to individuals with mental, emotional, or physical disabilities who may require special care or assistance to communicate, ambulate, perform self-care activities, or make decisions. Types of special needs include autism, Down syndrome, speech and language impairments, reading and learning disabilities, and cerebral palsy. Individuals with conditions that affect attention, memory, or communication, such as Alzheimer disease and ADHD, may also be included in this category.

Individuals with special needs require assistance or accommodation in all settings. For example, parents and

care providers can create a safe home environment by using safety equipment, such as smoke alarms that signal with a light, handrails to prevent falls, and life jackets for water safety that are specially fitted to the individual. If the individual with special needs is a wanderer, family can talk with neighbors and ask for their help keeping watch and to contact them if they see the individual unsupervised. As appropriate, the individual with special needs can wear a bracelet or some other kind of identification. Special locks or alarms on exit doors may be necessary to alert caregivers that the individual is trying to leave the building.

TABLE 51–9 Strategies for Promoting Safety in Community-Dwelling Older Adults

Strategies to Prevent Injury	Strategies to Prevent Disease
<ul style="list-style-type: none"> ■ Maintain mobility, activity, and function as tolerated and able to do ■ Have safety supports in the home for mobility, such as handrails, shower seats, chairs with adjustable heights, adequate lighting, and low beds ■ Seek help when needed for household upkeep, yard maintenance, repair work, and so on ■ Minimize clutter in the home ■ Wear footwear with skid-resistant soles ■ Keep assistive devices such as canes, walkers, glasses, and hearing aids, close and accessible to use ■ Know about prescribed medications and their side effects ■ Be aware of physical limitations to avoid injuries and accidents ■ Socialize with others for psychosocial healthiness as desired 	<ul style="list-style-type: none"> ■ Schedule an annual comprehensive assessment of physical, cognitive, emotional, and functional status ■ Maintain appropriate body weight by eating a variety of fruits, vegetables, and proteins ■ Drink adequate fluids to stay hydrated ■ Exercise joints and muscles to maintain mobility and flexibility ■ Do assessment self-checks for changes to skin integrity, respiratory status, musculoskeletal movements, and routine body functions ■ Be actively engaged in health safety behaviors such as frequent hand washing ■ Be aware of surroundings and alert for safety hazards to avoid ■ Avoid temperature extremes

Figure 51-9 >> Because of IDEA, all students are guaranteed a free and appropriate education. Here a boy with cerebral palsy works with his aide in the classroom.

In school systems, the Individuals with Disabilities Education Act (IDEA) mandates the provision of a free and appropriate public school education for individuals who have a disability that adversely affects academic performance or need special education and related services (**Figure 51-9** >>). During the school year 2012–2013, about 6.4 million children or about 13% of all public school students were receiving special education services (National Center for Education Statistics [NCES], 2015). Individuals with special needs may be bullied, teased, or harassed physically, verbally, or socially leading to feelings of low self-esteem, health problems, and depression. Individuals can learn how to protect themselves from bullying with instruction and by practicing behaviors at home. They can also learn safe people to go to while at school, such as the school counselor, teacher, or security guard.

Here are suggested questions to address for safety and injury prevention:

1. Can the individual move about, handle things, and explore?

2. Is there any safety equipment or modifications that are appropriate for the individual?
3. Does the individual have difficulty talking or understanding?
4. Does the individual have difficulty making decisions? (CDC, 2014b)

Individuals with special needs depend on others to help them have safety and security. Parents and other family members may need assistance to locate community resources to help provide appropriate care and respite care. Nurses can assess what needs the individual has that will require assistance from others and discuss resources with the family. Nurses can provide support and encouragement for the individuals and their families. Teaching is important to show family members how equipment, supplies, and procedures are used or performed. A team of caregivers may be essential to provide supervision and care. This also can provide a variety of relationships with caregivers and the special needs individual. Family members may need encouragement and support to accept respite care as a time of refreshing and reenergizing without feelings of guilt. Strategies for promoting safety for individuals with special needs are outlined in **Table 51-10** >>.

NURSING PROCESS

Individualized patient care includes appropriate developmental and chronologic health promotion and injury prevention considerations. Safety is often a priority. Nurses need to take into account safety hazards that may result in injuries associated with all age groups across the lifespan, such as accidental poisoning for small children or falls for older adults.

Assessment

Both objective and subjective data are used to assess the need for maintaining the current level of health or readiness to improve it:

- **Observation and patient interview.** History of lifestyle risk behaviors, frequency of injuries from chronic conditions,

TABLE 51-10 Strategies for Promoting Safety for Individuals with Special Needs

Strategies to Prevent Injury	Strategies to Prevent Disease
<ul style="list-style-type: none"> ■ Adapt safety restraints and seats in motor vehicles as appropriate to keep individual safe ■ Advocate to have neighborhood audible crosswalk signals installed ■ Have safety evacuation plans at home for fire, include flashing lights for hearing impaired, include special equipment as appropriate ■ Install soft surfaces in outside play areas ■ Match sports activities to individual's abilities ■ Provide special equipment or protection for individuals needing assistive devices ■ Match toys, games, and hobbies to individual's developmental level ■ Dress appropriately for the weather ■ Be alert for home safety issues: electrical outlets, electrical cords, climbing on furniture, hot water temperature; knowing where to find bathroom, bedroom, dining room 	<ul style="list-style-type: none"> ■ Avoid secondhand smoke exposure ■ Teach individual to brush teeth, have scheduled dentist visits ■ Encourage adequate sleep and rest ■ Teach individual safety around strangers ■ Maintain airway with suctioning as needed, or if able, effective coughing ■ Teach individual about hand washing and using a telephone to call for help ■ Schedule routine immunizations for age group ■ Provide oxygen therapy as prescribed

developmental challenges, sensory and motor deficits, change in sustainability of current health status, changes in family dynamics, ability to live independently, and so on

- **Physical examination.** Vital signs, heart and lung sounds, mobility, sensory and motor disabilities, changes due to lifestyle risk behaviors, cognition abilities, current injuries noted, and so on.

Diagnosis

There are many NANDA-I nursing diagnosis labels about promoting health and preventing injuries for all ages of patients. Promoting health can focus on psychologic, emotional, physical, spiritual health, and preventing injuries can address environmental conditions, the patient's current state of well-being, or the patient's homeostasis status. Here are a few common examples of safety and health promotion nursing diagnoses:

- *Protection, Ineffective*
- *Health Behavior, Risk-Prone*
- *Health Maintenance, Ineffective*
- *Self-Care, Readiness for Enhanced.*

(NANDA-I © 2014)

Planning

Goals for improved health reflect the nursing diagnosis label and include input from the patient, such as:

- The patient will assess his skin for lesions every month.
- The patient will verbalize three ways to be physically active each day.
- The patient will actively participate in a community-based smoking cessation program.
- The patient will be able to correctly demonstrate how to empty his colostomy bag by discharge.

Implementation

There are many nursing actions that help patients improve their health while in a healthcare setting (acute care facility, extended care facility, community facility, or home setting). There are many opportunities for nurses to teach patients about being more active in safe self-care behaviors to prevent injuries. All interventions need to be prioritized to best meet patient needs. Some intervention examples are:

- Demonstrate to patient how to use a mirror to assess for skin lesions on his back.
- Assist patient in finding a smoking cessation program in his community.
- Encourage patient to observe and then participate in emptying his colostomy bag.
- Collaborate with the physical therapist to teach patient appropriate physical exercises.

Evaluation

Expected outcomes may include the following:

- The patient is able to correctly empty his colostomy bag when needed.
- The patient attends a smoking cessation program in his community.
- The patient is able to verbalize how to assess for lesions on his back using a mirror.
- The patient is able to demonstrate three physical activities that can be done during the day.

The safety and health conditions of a patient can change quickly. Because of this, the nurse needs to continuously monitor the patient's health status by observing for cues indicating a difference between previous and current assessment data. Promoting safety and well-being for the patient needs to be a priority during every nurse-patient interaction.

REVIEW Health Promotion and Injury Prevention Across the Lifespan

RELATE Link the Concepts and Exemplars

Linking the exemplar on health promotion and injury prevention across the lifespan with the concept of culture and diversity:

1. Discuss how an individual's culture may impact his or her environmental exposures and lifestyle choices.
2. How might the nurse integrate cultural considerations in an assessment of an individual's safety throughout the lifespan?

Linking the exemplar of health promotion and injury prevention across the lifespan with the concept of communication:

3. Differentiate ways of teaching an adult, a school-age child, and a toddler about hand hygiene safety.
4. Contrast safety considerations when providing care to a primary English-speaking patient and to a patient who speaks English as a secondary language.

READY Go to Volume 3: Clinical Nursing Skills

REFER Go to Pearson MyLab Nursing and eText

- Additional review materials

REFLECT Apply Your Knowledge

An older adult patient was admitted to the hospital 3 days ago subsequent to a fall. She sustained a right hip fracture and a mild concussion. The patient had been outside gardening on an afternoon where the temperature reached a high of 92 degrees. When she stood up to walk in the house, she experienced vertigo and fell to the ground. After she recovers from surgical repair of her hip fracture, she will be transferred to a rehabilitation facility.

1. How might age-related physiologic changes have contributed to the patient's fall and subsequent injuries?
2. Why is the patient being transferred to a rehabilitation facility, as opposed to being discharged to her home?
3. Develop a nursing plan of care for the patient.

Exemplar 51.B Patient Safety

Exemplar Learning Outcomes

51.B Analyze safety as it relates to patients in home care and healthcare settings.

- Evaluate the quality of safety in home care settings.
- Write safety nursing interventions for patients in healthcare settings.
- Contrast lifespan considerations for safety in healthcare settings.
- Plan nursing interventions for quality, safety, and best patient outcomes.

Overview

Individualized patient care incorporates numerous developmental considerations. Patients who present with illness or injuries are assessed not only in terms of their developmental age group, but also about safety concerns for the age group. Nurses need to take into account common injuries and safety hazards associated with all age groups across the lifespan. These considerations for safety should take place in all healthcare settings; acute care facilities, extended care facilities, community settings, and home settings.

Safety in Home Care Settings

Home healthcare has become an established regulated program of care and services that older adults are using more now that they are living longer. A variety of medical, therapeutic, and nonmedical services, such as wound care, dietary counseling, physical therapy, skilled nursing services, occupational therapy, and homemaker services, are now available in private homes from healthcare professionals. Data show that 23.1% of noninstitutionalized older adults are in fair or poor health, so many need some level of assistance in the home. The home health industry is responding to these needs (CMS, 2015).

As the older adult population continues to grow, so does the suspected number of unreported elder abuse cases (National Center on Elder Abuse [NCEA], 2015). **Elder abuse** is defined as intentional actions by a family member, caregiver, or other that inflicts harm or puts the older adult at risk for harm, including failure to meet basic needs or protect the older adult from harm. In a national study, it was reported that approximately 90% of abusers were family members (NCEA, 2015).

Older adults over the age 65 with disabilities are more vulnerable to abuse that puts their health, safety, well-being, and ability to take care of themselves at risk. Another high-risk group for abuse is those with dementia. Victims of elder abuse and neglect have additional health conditions, such as digestive problems, depression, anxiety, chronic pain, and

heart problems. Many older adults on fixed incomes also experience financial exploitation with very damaging losses affecting their lifestyles and ability to take care of themselves (NCEA, 2015). See the exemplar on Abuse in the module on Trauma for further information.

» Stay current: Learn more about federal and state policies on elder abuse at <https://ncea.acl.gov/index.html>.

There are many environmental improvements that address safety risk measures in home settings. Best patient outcomes from these interventions could include that the patient remained unharmed, did not fall, was comfortable with room temperatures, remained accident free, and felt secure and safe. These improvements can be adapted to individual home settings. Examples of environmental safety improvements are:

1. Installing handrails along the walls
2. Installing grab bars in the bathroom, at toilet and tub/shower areas
3. Designing wider hallways and doorways for using walkers and wheelchairs
4. Installing easy-grip door handles, water faucets, and cabinets
5. Removing scatter rugs or adding nonslip padding underneath
6. Ensuring that a bell or way to call for help is easily accessible
7. Providing adequate lighting
8. Using raised toilet seats
9. Giving the patient the ability to control room temperatures for comfort
10. Ensuring that fire and disaster plans are available.

Older adults with one or more chronic illnesses may be taking medications that can increase risk for confusion or compromise mobility. Nurses working with patients from this population assess for risks to safety related to both prescribed and over-the-counter medications and supplements (see the Patient Teaching feature).

Patient Teaching

Promoting Medication Safety for Older Adults

Nurses can provide patient teaching to help older adults and their families know how to reduce the risk of harm related to medications and in particular from **polypharmacy**, which is using a large number of medications for one or more conditions. The following suggestions can help promote medication safety for older adults in a home setting:

1. Carry a list of medications to each appointment with a healthcare provider. Share the list with a family member.
2. Take medication as prescribed until it is finished, especially antibiotics, or discontinued under the direction of the healthcare provider. Do not skip doses of medication.
3. Use a pill organizer, or ask a family member or close neighbor for help filling pill compartments for each day of the week.
4. Keep emergency and contact phone numbers near the telephone.
5. Do not store multiple medications in a single container; this can make it difficult to identify individual medications.
6. If the patient has difficulty remembering to take medications, reading labels, hearing instructions, swallowing tablets or capsules, or opening medication bottles, encourage the patient to inform the pharmacist and all healthcare providers and to ask a family member or close neighbor for assistance as needed.
7. If the nursing assessment indicates that the patient needs regular assistance taking medications, work with the patient to come up with solutions that ensure the patient's safety, such as having a family member or a friend assist with medications.

Safety in Healthcare Settings

Because patient care can be very complicated in the healthcare setting, there is a need for coordination, flexibility, and adjustments made among the team of physicians, nurses, and other disciplines involved. Treatment protocols can be complicated and time sensitive; healthcare providers can modify their prescribed orders by changing them, adding new ones, or stopping old ones by the telephone, face-to-face, or in writing. Keeping quality and safety priorities for everyone is a continuous challenge.

Communication of patient information, called **handoff reporting**, between nursing units, between shifts, other departments, staff, and physicians is critical. Unfortunately, it is also a common cause of error if not all patient information is given, or if there is not enough time to give complete information and information about the patient is fragmented (The Joint Commission, 2013). To organize necessary patient information and standardize handoff communication, many healthcare facilities are using a communication tool called **SBAR**, which stands for:

- S**ituation
- B**ackground
- A**ssessment
- R**ecommendations

For further information, go to the module on Communication, and see **Figure 51-10** ».

For these reasons, and despite the best intentions of nurses and other providers, adverse events and medical errors occur frequently. Healthcare staff constantly strive to keep these adverse events to a minimum, targeting common clinical occurrences such as adverse drug events, falls, healthcare-associated infections (HAIs), improper use of restraints, and wrong-site surgery (WSS) (CDC, 2015f). Unfortunately, in some healthcare facilities safety may not be a high priority, leading to complacency and tolerance of low performance, which can contribute to poor quality and patterns of unsafe behaviors and uncaring attitudes.

Adverse Drug Events

Injuries that result from medication-related medical interventions are called **adverse drug events (ADEs)** (ODPHP, 2015b). They can occur anywhere throughout the medication administration process, starting when medications are pre-

SBAR Report

Figure 51-10 » Information included in an SBAR handoff report.

scribed and ending when patients receive them. ADEs can occur in a variety of healthcare settings such as acute care hospitals, outpatient clinics, physician offices, community offices, extended care facilities, and home care settings. They can involve professionals who prescribe, prepare, and administer medications, and patients who receive medications.

Approximately 1 of 3 inpatient hospital adverse events are due to ADEs, affecting about 2 million hospital stays per year by extending those hospital stays by 1.7 to 4.6 days. In outpatient settings, ADEs yearly cause more than 3.5 million physician office visits, approximately 1 million emergency department visits, and about 125,000 hospital admissions (ODPHP, 2015b). The majority of ADEs are preventable. High-alert medications, such as insulin, anticoagulants, and opioids, have the highest risk of causing harm and thus require special alertness to safety guidelines when administering them. Nurses can provide safe medication administration by following rights of medication administration, including:

1. **Right assessment**
2. **Right drug**
3. **Right dose**
4. **Right patient**
5. **Right route**
6. **Right time**
7. **Right documentation.**

By ensuring that the right assessment has been done and the right medication and the right dose are being given to the right patient at the right time and by the right route, the nurse acts to ensure quality and safety for the patient, protecting the patient against the possibility of adverse effects or an overdose. In addition, by correctly documenting when and how the medication was given (as well as which medication at what dose), the nurse prevents anyone else from accidentally duplicating administration of the medication order. Patient teaching to avoid medication errors is outlined in **Box 51-2** ».

Falls

Falls are very common in healthcare facilities and homes and are a special risk for those age 65 and older. One third of older adults fall every year (National Patient Safety Foundation [NPSF], 2013). Falls among older adults result in 2 million

emergency department visits every year, making falls the most common cause of nonfatal injuries and the leading cause of injury death in older adults (CDC, 2013c). In nursing homes, 50–75% of residents fall each year, with an average of 2.6 falls per person per year (CDC, 2013f).

Falls can cause numerous injuries, including fractured bones, excessive bleeding, traumatic brain injury, and death. Patients who display memory impairment and muscle weakness, as well as those individuals who require assistive devices such as canes or walkers for ambulation, are especially at risk. Numerous prescription and over-the-counter medications also increase the risk of falls (CDC, 2013f).

In a clinical setting, numerous strategies can be implemented to reduce the risk of falls. Examples of nursing interventions that may be applicable to the care of the patient who is at risk for falling may include the following:

- Remove obstacles from walking paths, including patient rooms, corridors, and stairwells.
- Keep frequently used items within easy reach.
- Ensure that patient rooms are well lit.
- Make sure patients wear shoes with soles that provide adequate traction, as opposed to wearing slippers or going barefoot.
- Assess the patient's vision and make sure he is using any prescribed eyewear, because poor and blurry vision increases the risk of falling.
- Use side rails on patient beds to prevent falls while the patient is sleeping.
- Be aware of each patient's medication regimen, including side effects and interactions, because side effects such as dizziness or drowsiness can substantially increase the risk of a fall. Request that a physician or pharmacist review patient medications when necessary (CDC, 2013e).

Healthcare-associated Infections

Healthcare-associated infections (HAIs) are infections that occur while a patient is being treated for another condition. Approximately 5% of hospitalized patients contract an HAI during their hospital stay (NPSF, 2013). Infections of this nature can be quite serious, because hospital patients are usually weaker or immunocompromised due to the injury or illness that hospitalized them in the first place. Common HAIs and pathogens that are commonly associated with HAIs are discussed in the module on Infection.

In 2011, the CDC prevalence survey based on a large sample of U.S. acute care hospitals showed that 1 in 25 hospital patients had at least one HAI. For the same year, there were approximately 722,000 HAIs in U.S. acute care hospitals. These HAIs resulted in an estimated 75,000 patient deaths during their hospital stay (CDC, 2015a).

The CDC HAI Progress Report for 2013 uses data reported to the CDC using the **National Healthcare Safety Network**. This is an annual report on progress at the national and state levels in preventing HAIs. On the national level, the report gave the following results between 2008 and 2013: (1) a 46% decrease in central line–associated bloodstream infections, (2) a 19% decrease in surgical-site infections related to the 10 select procedures tracked, (3) a 6% increase in catheter-associated urinary tract infections, (4) an 8% decrease in

Box 51-2

Medication Teaching

Nurses can help prevent medication errors in a number of additional ways, including by engaging patients and discussing their medication with them. Medication teaching begins with assessment of current medications prescribed as well as patient's use of them and use of over-the-counter medications and supplements. Medication teaching includes:

- The name and function of each medication.
- When and how medication should be taken.
- Common side effects and how to address them.
- Adverse effects that should be reported to the provider.
- Drug interactions with other drugs, food, and diseases.

hospital-onset methicillin-resistant *Staphylococcus aureus* (MRSA) bacteremia, and (5) a 10% decrease in hospital *Clostridium difficile* infections (CDC, 2015f).

Patients can help prevent infection through becoming knowledgeable about their treatment and recovery plan, being proactive about blood sugar control, losing weight prior to surgery, and quitting smoking. Nurses are also vital in preventing HAIs and must take appropriate measures to ensure that they are not unknowingly spreading illness between patients. Among other safety measures, appropriate hand hygiene and disinfectant techniques are particularly important.

Safety Devices

Safety devices include a variety of physical restraints that are intended to partially or fully limit the patient's mobility. They are applied only when absolutely necessary to protect the patient from injuring self or others and only with a physician's order. Two other types of safety restraints are chemical restraints and seclusion.

Chemical restraints are pharmacologic agents, such as sedatives, hypnotics, neuroleptics, and antianxiety medications, that are administered to agitated patients to control unsafe physical movements and behaviors. **Seclusion** is confining a patient to a room involuntarily and preventing the patient from leaving. Typically, acute care units do not have space for a seclusion room, so this category is more appropriate for emergency departments and psychiatric units than acute care settings. Other devices that may be considered forms of restraints include wheelchairs with stationary lap trays, bed rails, and geri chairs. Generally, if the patient can release or remove the device without assistance, the device is not considered to be a restraint. Infant and child restraints include crib nets, elbow restraints, and mummy restraints.

Physical restraints are wrapped, buckled, or tied to a patient's arms, legs, or trunk of the body to limit or restrict movement. They cannot be used as a form of punishment, a convenience measure, or to prevent a patient from leaving a given setting. Regulations stipulate the following conditions for restraints: (1) a physician or other healthcare provider must order specific restraints, physical or chemical, to be applied to the patient, (2) the order for restraints cannot be a standing order or prn order, and (3) when there is an urgency to protect the patient and others, restraints can be applied and then the physician can be notified as soon as possible for an order. Legally, a competent patient who simply does not comply with his care cannot be restrained; this may be construed as assault and battery or false imprisonment.

Restraint alternatives and least restrictive forms of restraint must be tried first, and if they are unsuccessful, then chemical or physical restraints can be implemented as a last resort for the safety of the patient and others. There must be documented evidence of less restrictive measures that were tried but unsuccessful, including interventions to modify the patient's behavior or the environment. Some examples of restraint alternatives to help control the patient's behaviors and avoid restraints include:

- Having a family member or sitter stay with the patient
- Using bed or chair alarms

- Using distractions and diversional activities
- Using a calm voice and soothing tone
- Limiting the number of staff working with the patient
- Using de-escalation strategies
- Using portable electronic GPS sensors to locate patient
- Reorienting the confused patient
- Assessing/addressing problems causing agitation such as wanting to get up and go to the bathroom, or wanting some water to drink
- Offering therapeutic self and reassurance (ASHRM, 2015).

Although restraints are intended to protect the patient, their use also may result in injury or even death. Psychosocial effects are also a concern; adult patients may experience depression, as well as a sense of dehumanization, and pediatric patients may feel they are being punished. Whenever restraints are used, the nurse must follow strict guidelines to ensure the patient's safety. These guidelines include:

- Assessment is to be done at least every 2 hours and includes skin and circulation status, patient's response, and effect of restraints
- New verbal order is needed every 24 hours if there is not a written order
- Removal of restraints must be done periodically so patient can freely move body part, range-of-motion (ROM) exercises can be done, and patient can be repositioned
- Toileting, food, and fluids are offered periodically
- Evaluation to determine if continued restraint is needed, and restraints reapplied if needed
- Appropriate and complete documentation of the restraint intervention.

Commonly used restraints include limb, soft belt, safety strap, or vest immobilizers or mitt, elbow, or hand restraints (**Figure 51-11** ▶). Limb restraints and mitts, which are typically made of cloth, may be used when limb immobilization is needed for therapeutic purposes—for example, to prevent dislodgement of an intravenous infusion device or removal of dressings. To ensure the safety of patients who are transported by wheelchair or gurney, soft belt restraints, safety strap body restraints, or vest restraints are used. Soft belt restraints and immobilizers may be used to protect patients who are confined to a chair or a bed. To protect confused patients or very small children from scratching and injuring their skin, mitt restraints, mittens, or hand restraints may be used.

Wrong-Site Surgery

Wrong-site surgery (WSS), or wrong-site, wrong-procedure, wrong-patient surgery, are errors that should not occur and are called **sentinel events** by The Joint Commission and **never events** by the National Quality Forum. **Wrong-site** refers to surgery performed on an incorrect body site or to surgery performed on the wrong side of the correct body site: for example, removing the right upper lung lobe instead of the left upper lung lobe, or removing the right side of the right upper lung lobe instead of removing the left side of

A

B

C

Figure 51-11 » Various types of restraints. **A**, Limb restraint. **B**, Belt restraint. **C**, Mitt restraint.

the right upper lung lobe. **Wrong procedure** refers to the right patient undergoing an incorrect surgical procedure. **Wrong-patient surgery** refers to the patient undergoing a surgical procedure intended for another patient. WSSs are fairly rare and happen approximately 1 in every 112,000 surgical procedures, averaging one such error every 5–10 years in a given healthcare facility (AHRQ, 2015). Some factors are:

- Inadequate patient assessment
- Inadequate safety culture
- Communication failure
- Inadequate medical record review
- Multiple procedures on multiple parts of a patient performed during a single operation

Patient Teaching

SPEAKUP for Safety

The Joint Commission launched a patient safety educational program called Speak Up™ to help individuals in healthcare and home settings be more aware of safety hazards that can cause injuries and accidents. This initiative educates patients and empowers them to be an active partner in their care. It has now expanded to more than 70 countries and has been translated in several languages (The Joint Commission, 2015).

Each year, new Speak Up™ campaigns are developed that provide patients a variety of safety topics to help them be safer in healthcare and home settings. Safety issues such as helping to prevent errors in care, decreasing the risk of falls, using antibiotics, and maintaining children's health are made available in English, Spanish, and other languages. The materials include animated videos, pamphlets, posters, and infographics that can be downloaded free. The **Speak Up** acronym stands for:

- S**peak up if you have questions or concerns
- P**ay attention when you receive care (medications, treatments, therapies)
- E**ducate yourself about your illness, medical history, and diagnoses
- A**sk a trusted friend or family member to advocate for you
- K**now what medications you take and why you take them
- U**se healthcare facilities that you have checked out
- P**articipate actively in decisions made about your care and therapies.

Source: The Joint Commission. (2015). *Our award-winning patient safety program. SpeakUp™*. Retrieved from <http://www.jointcommission.org/speakup.aspx>.

- Failure to include the patient and family when identifying the correct operation site
- Failure to clearly mark the correct operation site
- Failure to recheck information before starting the operation.

WSS is a serious patient risk, because it subjects a patient to severe and unnecessary trauma. Surgery teams also feel the effects because they can be subjected to negative morale, insurers that will not pay for WSS, malpractice claims, and disciplinary actions by licensing boards. To prevent WSS, The Joint Commission developed a universal protocol that has been adopted by numerous medical and professional organizations. The universal protocol is outlined in the module on Perioperative Care (The Joint Commission, 2015).

Lifespan Considerations in Healthcare Settings

Healthcare facilities are strange environments, full of strange new sounds, people, equipment, and activity. Preparing for this experience can help reduce patient anxiety and promote patient comfort and satisfaction with care. In general, giving patients honest information at a level they can understand, answering any questions they may have, and providing

them support and encouragement will help them be more at ease. The following sections present some common safety considerations for pediatric, pregnant, and geriatric patients.

Safety Considerations for Pediatric Patients

1. Very young children learn about their world by touching and playing with objects around them, so keep medications, sharp objects, and equipment out of reach.
2. Suggest parents bring in a few comfort items the child is familiar with, such as photos, a favorite blanket, or a favorite small toy.
3. Maintain the child's daily routines and habits as much as appropriate.
4. Suggest that parents help their child stay busy with age-appropriate activities they like to do.
5. Encourage parents to respect safety signs such as washing hands, keeping a security door closed, and not allowing the pediatric patient to run down the hallways or be out of their sight at any time.
6. Be aware when parents leave the child alone.
7. Remember that children and infants can move very quickly and fall from a crib or bed.
8. Communicate with children using language that is appropriate for their developmental level.
9. Infant and child patients must wear proper identification at all times.
10. Nurses should provide patient-centered care and also family-centered care to keep the patient and family engaged in how they can support the quality and safety of care.

Safety Considerations for Pregnant Patients

1. Patients need to continue to follow prenatal care guidelines as approved by their healthcare provider.
2. When patients have chronic conditions requiring treatment, such as asthma, diabetes, or heart problems, they should be more careful about managing these conditions. Their healthcare providers may change or stop certain medications or treatments during their pregnancy.
3. Patients need to know how medications, procedures, and treatments could affect their pregnancy or their child. Nurses can reinforce information provided by the patient's treating physician or provider.
4. Nurses can encourage pregnant patients to do safety behaviors and be especially careful to avoid risks of infection, injuries, and accidents.
5. Nurses can encourage pregnant patients to use their call button to ask for assistance to get out of bed or move about to prevent falls.

Safety considerations for the newborn include teaching the mother and other family members to never leave the baby alone in the mother's room, only give the baby to personnel with appropriate photo identification name badges, always use an infant crib when transporting the baby, always leave the baby on the postpartum unit, and never give interested

strangers on the unit personal information about themselves or the baby.

Safety Considerations for Geriatric Patients

1. Encourage patients to have a family member or someone they trust to advocate for them while they are in the hospital.
2. Encourage patients to have someone bring their prescription and over-the-counter medications, herbs, and dietary supplements to the hospital to review and include in their admission information.
3. If a patient has any known allergies to medicines, materials, foods, soaps, and so on, this information needs to be posted in appropriate places such as on the medical record, the medication administration record, and as hospital policy dictates.
4. Emphasize to patients the importance of using the call button to ask for help getting up to the restroom or walking around the hallway.
5. Emphasize to patients the need to keep the bed in a low and locked position with upper side rails raised.
6. If a patient will be in the hospital for a few days, suggest that a family member bring in a few comfort items familiar to the patient, such as a bathrobe, photo, or favorite item.
7. Help patients and family members be comfortable with asking questions about care, diagnostic tests, or procedures for understanding.
8. Emphasize the importance of wearing an identification band while in the hospital and encourage patients to make sure it is checked before receiving medications or treatments.
9. Discuss routines of mealtimes, bathing, procedures, treatments, and other care with patients and, as appropriate, accommodate any cultural, spiritual, or personal rituals, habits, or activities patients would like to continue doing while in the hospital.
10. Communicate with patients in their language and at their developmental level for understanding. Provide orientation of day, place, and name to patients as needed.

NURSING PROCESS

Individualized patient care includes appropriate developmental and chronologic age-specific safety considerations. Safety is a common priority for many patients because of motor or sensory changes from acute or chronic conditions inhibiting functional abilities to protect themselves. For example, patients who have had strokes may not independently be able to reposition themselves to protect the integrity of their skin from breakdown, and children with cystic fibrosis may not be able to cough up and remove their secretions in order to protect their airways and keep them open for air exchange.

Assessment

Both objective and subjective data are used to assess the safety needs of patients:

- **Observation and patient interview.** History of falls, balance issues, medications that may cause orthostatic

hypotension, chronic conditions, mobility deficits, sensory deficits, and so on

- **Physical examination.** Vital signs, ROM, skin assessment, hearing or visual difficulties, heart and lung sounds, tremors, impaired balance, and so on

Diagnosis

Because of the nature and large number of safety hazards in healthcare settings, there are many NANDA-I nursing diagnosis labels appropriate for patients focused on safety. Safety can include elements in the environment, the patient's situation, or the patient's homeostasis status. Here are a few examples:

- *Knowledge, Deficient*
- *Skin Integrity, Impaired*
- *Airway Clearance, Ineffective*
- *Thermoregulation, Ineffective*
- *Risk for Infection* from bleeding, falls, injury, poisoning, and suicide.

(NANDA-I © 2014)

Planning

Safety goals are decided on by the patient and the nurse and would reflect the nursing diagnosis label, such as:

- The patient will have clear breath sounds by discharge.
- The patient will be able to correctly demonstrate walking with a cane 25 feet by (date).
- The patient will remain free from infection, bleeding, falls, injury, poisoning, and suicide.
- The patient will verbalize three things to do to safely get up out of the bed and sit in the chair by (date).

Implementation

There are many nursing actions that can be done to keep patients safe while in a healthcare setting (acute care facility, extended care facility, community facility, or home setting).

There are many opportunities for nurses to teach patients about using safety behaviors to prevent accidents. All interventions need to be prioritized to best meet the safety needs for the patient. Some intervention examples are:

- Assess patient's feet for cracking and dryness and apply lotion after bathing time.
- Collaborate with the physical therapist to teach patient correct cane walking.
- Encourage the patient to use the incentive spirometer every hour while awake as tolerated.
- Staff will promptly respond when patient's call light is activated for assistance to get up to the restroom.

Evaluation

Expected outcomes may include the following:

- The patient has clear breath sounds at time of discharge.
- The patient is able to correctly demonstrate walking with a cane for 25 feet.
- The patient remains free from infection, bleeding, falls, injury, poisoning, suicide, and so on.
- The patient is able to verbalize three things to do to safely get up out of the bed and sit in the chair.

The nursing plan of care follows a sequence of actions that have a causal relationship. Clustering assessment data results in the identification of the nursing diagnosis; the nursing diagnosis informs goal setting; goals stimulate decisions regarding what interventions will help the patient reach the goal; and evaluation is completed to determine if the interventions were successful in supporting the goal to be obtained. If the goal is not reached, the whole process is reevaluated to determine if the goal and interventions were appropriate for the assessment data and nursing diagnosis. Changes in the goal or interventions may be necessary to individualize them for best patient outcomes.

REVIEW Patient Safety

RELATE Link the Concepts and Exemplars

Linking the exemplar of patient safety with the concept of perioperative care:

1. The nurse notices that the child patient waiting to go to surgery is drinking a glass of milk. What are the priority safety actions for the nurse? Why?
2. Immediate postoperative assessment of the patient postanesthesia would include which priority safety data?

Linking the exemplar of patient safety with the concept of mood and affect:

3. Sometimes patients who are in the manic phase of bipolar disorder are placed in seclusion for a period of time. What are the safety concerns of the staff for making this decision?
4. Is it a potential safety problem when a depressed patient begins putting her affairs in order? Why or why not?

Linking the exemplar of patient safety with the concept of acid-base balance:

5. When a diabetic patient has hyperglycemia, the blood pH goes down indicating metabolic acidosis. How will the body attempt to correct the metabolic acidosis and return to a pH within normal range?
6. When a patient overuses bicarbonate of soda for his indigestion problem, what safety problem might this cause for the patient's acid-base balance? What needs to be done to correct it?

REFLECT Apply Your Knowledge

A 9-year-old patient is admitted for observation to the medical unit with closed head trauma after falling off his bicycle and hitting his head; he was not wearing his safety helmet. He is drowsy, crying at times, and complaining of a headache. He had two episodes of vomiting while in the emergency department. Last set of vital signs were T—98.8°F, P—102, R—16, B/P—108/72, O₂ saturation 96% room air. His pupils are slightly sluggish but PERRLA. His HOB is to be elevated 30 degrees. Phenytoin has been ordered 125 mg IV BID, and he can have acetaminophen 480 mg po every 6 hours prn headache.

He is currently NPO and to have neuro checks every 2 hours using the Glasgow Coma Scale.

1. What are priority safety considerations with this patient?
2. What might be the reason the patient is receiving phenytoin? What might be the reason he is NPO? What might be the reason his HOB is up 30 degrees?
3. What priority teaching should the nurse identify at this time to do when the patient is more alert and awake and the parents are present before discharge?

» Exemplar 51.C Nurse Safety

Exemplar Learning Outcomes**51.C Analyze safety as it relates to being a nurse.**

- Outline the agencies that regulate workplace safety for nurses.
- Describe the etiology and prevalence of injuries to nurses.
- Summarize strategies to prevent injury in nursing practice.

Overview

Workplace safety is a concern in most professions, but it is of particular concern to healthcare workers. In 2014, of the more than 18 million individuals working in healthcare occupations, registered nurses had the highest employment number, a total of 2.7 million (BLS, 2015a). All of these occupations face numerous risks on the job. Some of these risks include bloodborne pathogens, needlesticks, latex allergies, musculoskeletal injuries, mental stress, and violence from patients. Injury and illness within the healthcare sector represent the highest percentage of nonfatal occupational injuries in any sector, including both construction and agriculture—two industries known for work-related injuries (CDC, 2013g).

Safety in the workplace is critical to job satisfaction and employee retention rates. In nursing, protocols for safety promotion and injury prevention have become more prevalent over the years. These protocols are designed to protect members of the healthcare team and patients.

Regulation of Workplace Safety

The Occupational Safety and Health Act of 1970 created both the **Occupational Safety and Health Administration (OSHA)** and the **National Institute for Occupational Safety and Health (NIOSH)**. OSHA is part of the U.S. Department of Labor. It is a national public health agency to protect workers from safety hazards and health risks in the workplace. NIOSH is part of the U.S. Centers for Disease Control and Prevention in the U.S. Department of Health and Human Services. It is a U.S. federal agency that conducts research and produces evidence used to find solutions and interventions to protect the safety and health of workers (CDC, 2017).

 Workplace violence, 2902

Occupational Safety and Health Administration

OSHA enforces the guidelines presented in the OSHA Act of 1970, requiring its covered employees to report specific incidents and illnesses in a timely manner. OSHA developed standards, enforcement actions, compliance assistance, and cooperative programs to prevent injuries and illnesses. OSHA enforces the rights of workers to have a safe work environment. Workers can file a complaint about unsafe work conditions through their whistleblower program asking for an on-site inspection of the situation from OSHA and will be protected from employer retaliation (U.S. Department of Labor, 2017).

One of the primary functions of OSHA includes consulting with both employees and employers regarding prevention methods for the injuries and illnesses that are most prevalent in each particular work environment. For example, OSHA's involvement with those in the nursing sector includes preventive measures against needlesticks, bloodborne pathogens, and aggression from patients. Inspections of the workplace are conducted by OSHA employees to ensure that individuals are complying with standards. In the healthcare setting, for example, hand hygiene procedures could be monitored, or the use of gloves when working with patients, or the availability of puncture-resistant sharps containers.

National Institute for Occupational Safety and Health

According to the CDC (2014c), "the mission of NIOSH is to generate new knowledge in the field of occupational safety and health and to transfer that knowledge into practice for the betterment of workers." NIOSH conducts scientific

research to provide advances in safety both in the workplace and for the population at large. In addition to research, NIOSH also develops recommendations for safety procedures, distributes information, provides training videos, and evaluates workplace health hazards.

Research conducted by NIOSH focuses on numerous topics relating to different sectors of the workforce. For example, NIOSH compiles research on the effects of stress in the workplace, which is particularly common in the healthcare community because of the nature of the work being performed. NIOSH can evaluate work environments for health hazards and recommend ways to reduce or eliminate them through its *Health Hazard Evaluation Program*.

Boards of Nursing

In order to protect the public's health and welfare from nurses who are not prepared or competent to provide safe nursing care, state governments used their police powers to enact laws to protect citizens and minimize harm of unsafe nursing practice. These laws are included in the **Nurse Practice Act (NPA)** of each state and authorized by the state's legislature. Each state has a Board of Nursing empowered to adopt, amend, or repeal rules and regulations as necessary. The guidelines in the NPA focus on safety parameters for nurses to provide safe and effective nursing care for public protection (NCSBN, 2012).

Boards of Nursing act to ensure safety by establishing academic requirements for nursing prelicensure programs, identifying standards for all areas from clinical learning experiences to faculty qualifications. Boards of Nursing also establish requirements for licensure, including taking the National Council Licensure Examination for Registered Nurse (NCLEX-RN) and continuing education requirements (NCSBN, 2015). Equally as important, Boards of Nursing establish procedures for reporting errors and violations made by licensed nurses and act to investigate such reports. Employers, coworkers, the public, healthcare facilities and others can send anonymous complaints to the Board of Nursing. Complaints about conduct include sexual misconduct, stealing, fraud, confidentiality issues, boundary violations, impairment while working, and drug diversion. Unsafe nurse practice includes inappropriate delegation, abandonment, neglect, exceeding scope of practice, and documentation issues (NCSBN, 2015).

» **Stay Current:** It is important for nurses to stay abreast of changes in the Nurse Practice Act in the state for which they work. Each state Board of Nursing will have this information. The NCSBN website has a list of all states at <https://www.ncsbn.org/npa.htm>.

Etiology of Injury and Illness

Injuries and illnesses in the workplace occur in almost every profession. Causes of workplace illness and injury vary by profession. The following categories make up the majority of workplace incidents resulting in fatalities: transportation accidents (41%), violence in the workplace (17%), trauma from objects and/or equipment (15%), falling or tripping (15%), exposure to dangerous environments or substances (9%), and explosions or fires (3%) (Bureau of Labor Statistics, 2013).

Prevalence

In 2012, a total of 4383 workers in the United States died from injuries sustained at work, an average of 12 deaths per

day. There were an estimated 2.8 million work-related injuries treated in emergency departments, resulting in 140,000 hospitalizations. Reports from employers included nearly 3 million injuries and illnesses to private industry workers and 793,000 injuries to state and local government workers (CDC, 2015a). All occupational injuries and illnesses have social and economic implications for the workers and their families, with medical costs, differences in quality of life-style, pain and suffering. Employers and society also share the burden for consequences of occupational safety and health hazards in the workplace.

One in five reported nonfatal occupational injuries involved healthcare and social assistance workers in 2013. This was the highest number of this type of injury reported throughout all private industries. In 2011, healthcare workers experienced seven times the national rate of musculoskeletal disorders when compared to all other private workers (CDC, 2015a). Data collection is dependent on national surveillance systems to record new cases and provide information that can be used to reduce occupational hazards and health issues to prevent injuries, illnesses, and death among healthcare personnel. To enhance details of data collected, NIOSH and others began the **Occupational Health Safety Network (OHSN)** to track injuries by type, demographic location, occupation, and risk factors. The three injury types recorded are (1) patient handling and movement; (2) slips, trips, and falls; and (3) workplace violence.

Injury data was collected by OHSN over a 2-year span of time that ended in September 2014. The data, which came from 112 healthcare facilities located in 19 states with a collective workforce of 162,535 full-time employees, reported 10,680 injuries: 4674 from patient handling and movement; 3972 from slips, trips, and falls; and 2034 from workplace violence (CDC, 2015a). Of the 4674 injuries from patient handling and movement, 82% occurred when lifting devices were not being used. Of the 3972 injuries from falls, 89% occurred from same-level falls. Of the 2034 workplace violence injuries, 99% were physical assaults and 95% were committed by patients. These figures are included in the total number of occupational injuries in healthcare reported by the National Bureau of Labor Statistics (Gomaa et al., 2015) (**Figure 51-12** »).

Nurses accounted for 38% of the 10,680 reported injuries. Nurses and nursing assistants had the highest injury rates of all other occupations reported. Using the data collected and analyzed, OHSN was able to identify how lifting devices and training could help reduce patient handling and movement injuries. Guidelines were made available to help protect personnel from common preventable injuries that could be disabling. Between 2012 and 2014, the rate of workplace violence injuries nearly doubled for nurses and nursing assistants and increased for all other occupations. These injuries occurred mainly on inpatient adult units, although incident numbers in emergency departments, stand-alone acute care centers, and critical care units were elevated. High fall rates occurred on inpatient adult units as well as nonpatient maintenance areas.

In 2013, there were 66,910 occupational musculoskeletal disorder injuries reported in the healthcare and social assistance private sector. Almost 50% of these cases included patients in acute and nonacute settings. Of the acute care cases, 20% were nurse musculoskeletal disorder injuries (BLS, 2015b). Injuries to nurses include pinched nerve,

Source: Data from Gornaa, A. E., Tapp, L. C., Luckhaupt, S. E., Vanoli, K., Sarmiento, R. F., Raudabaugh, W. M., ... Sprigg, S. M. (2015). Occupational traumatic injuries among workers in health care facilities—United States, 2012–2014. *Morbidity and Mortality Weekly Report (MMWR)*, 64(15), 405–410.

Figure 51–12 » Categories of 10,680 injuries reported by healthcare employees over a 2-year study.

herniated disk, meniscus tear, sprains, strains, tears, carpal or tarsal tunnel syndrome, and musculoskeletal system and connective tissue diseases. Nurses are at high risk for these injuries because of their work patterns, the increased acuity of patients, the need to keep patients mobilized, and the increase in obese patients. Increased resources such as training, lifting devices, and lift teams can potentially reduce the number of occupational injuries of healthcare workers. Healthcare facilities can establish and support a safety culture among their employees. Emphasis on occupational safety and health practices can promote a safer work environment and support patient safety. OHSN can help healthcare facilities identify hazards of safety and health and provide them with a variety of tools and materials to improve employee safety and health. These strategies can protect healthcare employees from injuries, accidents, and illnesses that could be disabling and life-changing.

Illness and Injury Prevention in Nursing Practice

Nurse safety from workplace-related health problems is important not only to nurses but also to the patients under their care. Nurses experience not only physical but also psychologic demands throughout their shifts. Pressures can come from workforce downsizing, working more hours, the work pace, increased acuity levels of patients, the escalating number of older patients, the complexity of the environment, extended workloads, an older nurse workforce, and potential for violence and chemical exposures. These factors can contribute to acute or long-term health problems from musculoskeletal injuries and disorders, infections, mental health changes, insufficient sleep patterns, and chronic exhaustion (AHRQ, 2008).

Work-related illnesses in nursing may arise from contact with contagious patients or from contact with bloodborne pathogens as the result of needlestick or sharps injuries.

Exposure to many illnesses can be minimized with simple measures such as hand hygiene and sanitization efforts.

There are many occupational hazards for nurses and other healthcare workers found in all healthcare settings, including acute care, extended-care, and community-based facilities and the home environment. In 2014, workplace illnesses accounted for 4.9% of the nearly 3.0 million injury and illness cases (BLS, 2015b). These hazards put healthcare workers at risk for a variety of safety concerns, including exposure to infectious diseases, such as blood and body fluid pathogens, and injuries or accidents. To create a safer work environment and prevent illness and injury in nursing practice, the focus needs to be on building an awareness of potential safety hazards and finding solutions to prevent them.

Nurses provide care for patients with diagnosed and sometimes undiagnosed infectious diseases such as influenza, norovirus, methicillin-resistant *Staphylococcus aureus* (MRSA), tuberculosis, and HIV (CDC, 2013g; Hospital Jobs Online [HJO] & Burgess, 2012). Vaccines are available to protect against some pathogens, and healthcare providers are encouraged to take advantage of employer-provided vaccination programs.

» **Stay Current:** Visit <http://www.cdc.gov/vaccines/adults/rec-vac/hcw.html> for current CDC recommended vaccines and changes in immunizations for nurses and other healthcare workers.

The CDC has developed comprehensive infection control recommendations that include standard, contact, and airborne precautions for all settings of patient care. Healthcare facilities and organizations that provide home healthcare services have policies and procedures that address safety infection control measures. The CDC provides considerations when choosing personal protective equipment to protect against infectious exposures. Guidelines for preventing the transmission of infectious pathogens are available. The proper use of respirators by nurses and other healthcare workers is another preventive practice. Information about the proper cleaning and sterilization of equipment and procedures to do the cleaning and sterilization are available to help prevent the transmission of infections. Nurses can implement the following tips to avoid illness:

1. Keep Tdap (combination vaccine for tetanus, diphtheria, and pertussis) immunization current; get boosters every 10 years
2. Take advantage of annual influenza vaccinations
3. Get the hepatitis-B vaccination series and maintain positive titers for adequate immunity
4. Get the MMR (measles, mumps, and rubella combination) vaccine following CDC guidelines
5. Get the varicella (chickenpox) vaccine following CDC guidelines (CDC, 2014d)
6. Perform frequent and complete hand washing or hygiene
7. Don personal protective equipment (PPE) following CDC guidelines *every time*
8. If working with a patient in isolation, call for assistance as needed
9. Avoid touching the nose, eye areas, and mouth on one's own face
10. Provide own self-care to keep the immune system healthy: appropriate diet, sleep, relaxation, activity, and self-time

11. If beginning to feel sick at work, go home as soon as appropriate
12. If feeling sick at home, don't go to work; stay at home.

Nurses must be vigilant in the prevention of injuries and illness in their workplace environment, in their nursing practice, and for their own personal safety. Healthcare facilities have policies for preventing injuries and maintaining a safe work environment. Safe practice and protocols can be implemented to sustain a nurse's well-being when working with infectious (or potentially infectious) agents, needles, latex, chemical exposure, and patient handling.

Needlestick Injuries

Needlestick and sharps injuries are a large and growing problem in the healthcare industry. It is estimated that approximately 385,000 sharps-related incidents occur each year in hospitals across the country. The CDC believes that over half of all sharps injuries are not reported as required, including those that happen to physicians, laboratory personnel, and housekeeping staff. Sharps injuries are very serious and can result in numerous illnesses. The *STOP STICKS* campaign, initiated by NIOSH, works to raise awareness of the risks associated with bloodborne pathogens most commonly associated with sharps injuries, such as HIV and hepatitis B and C. Although this campaign was originally developed for emergency departments and operating rooms, the ideas extend to all other healthcare fields that use sharps. The *STOP STICKS* campaign provides resources for exposure prevention methods and equipment evaluations and the requirements for sharps disposal containers (CDC, 2013c).

Nurses incur most injuries from reported needlesticks (CDC, 2013h). When working with used or contaminated sharps, nurses should employ extra precautions so as to avoid unnecessary injuries. Needles that have been used are almost never recapped (unless this is necessary because of protocol) and are disposed of in an appropriate sharps container. Approved disposal containers should be present wherever sharps are being used and must be both puncture resistant and leakproof on the bottom and all sides. If sharps do need to be recapped, this should be done with the use of another device (such as a hemostat), or with the **scoop method**. In the scoop method, the cap is placed on a table or hard surface and the tip of the needle is guided into the cap; to ensure the cap is on tight, it can be pressed against a hard surface such as a table or wall. Nurses should *never* hold the cap in one hand while trying to guide the tip of the needle into the cap with the other—this method substantially increases the risk of a sharps-related injury. Needlestick and sharps injuries arise from a number of different situations, such as not implementing proper disposal techniques, failure to recap the needle, bumping into an uncapped and used needle, or contact with a used scalpel (CDC, 2013h).

» **Stay Current:** Visit <http://www.cdc.gov/niosh/stopsticks/> for more information on the STOPSTICKS campaign.

Chemical Exposure

Nurses can be exposed to a high level of chemicals used in sterilizing, pest control, volatile organic compounds such as formaldehyde, and pharmaceuticals such as antineoplastics. These products come in a variety of forms, including gas,

aerosol, and skin contaminants, so they can be absorbed through the lungs or skin. Exposure may be a one-time occurrence, but it can also occur over time. Some chemicals are regulated in terms of exposure, requiring employees to take more precautionary measures when handling these substances. However, many common chemicals and compounds can cause both injury and illness if they are accidentally spilled or ignited (OSHA, 2015).

Safe Patient Handling

The Nurse and Healthcare Worker Protection Act of 2009 was proposed in an effort to prevent injuries to nurses, healthcare workers, and patients. The act discusses the large number of musculoskeletal disorders and injuries that affect nurses that are often the result of helping to move, lift, or reposition patients. The safe patient handling and injury prevention standard within the act requires the use of mechanical devices to lift or move patients, unless the use of these devices proves to be unsafe or is contraindicated for the patient for some reason. Using mechanical devices to help move patients aids in avoiding unnecessary musculoskeletal injuries for both nurses and other healthcare workers (**Figure 51-13** »). The act also establishes extensive training in safe patient handling methods for all nurses (Govtrack, 2015).

Effective and safe patient handling helps to promote patient safety as well as nurse safety. Patient handling can be done more safely by using height-adjustable electric beds, mobile mechanical and ceiling-mounted patient lifts, anti-friction devices, band transfer aids, and bed or chair repositioning. Another strategy is to have peer safety leaders available to help nursing staff make practice changes to improve safety.

Workplace Violence Protection

Workplace violence is defined by NIOSH as “any physical assault, threatening behavior or verbal abuse occurring in the work setting” (CDC, 2014e). Nurses and other healthcare workers are at particular risk of violence in the workplace. Violence can come from patients, their families, or visitors, because of inadequate workplace security, unrestricted movement by visitors around the healthcare facility, personal relationship altercations in the workplace, or a healthcare

Source: Trish233/iStock/Getty Images.

Figure 51-13 » Nurses using a floor-mounted mechanical lift to move a patient.

worker bullying another worker. Although routinely there are higher risks of injuries from assaults by patients or their families in an emergency department or mental health nursing unit, no department in a healthcare facility is immune from workplace violence. Potential injuries include nurses being scratched, hit, kicked, beat, bitten and sometimes threatened with weapons such as knives or guns.

Some strategies to prevent workplace violence are: keep hair tucked away, use breakaway lanyards, be aware of and note any change in surroundings, note verbal and nonverbal cues that signal increasing patient agitation or anger, note inappropriate abusive language or behaviors from coworkers, and note signs that someone may be acutely emotionally upset to the degree that he or she is unable to think clearly with a change in rational behaviors. Some healthcare facilities offer employees training in managing aggressive behaviors (**Figure 51-14** »).

Many states have enacted legislation to address violence in the workplace by increasing punishments for those who attack nurses and by requiring employers to provide training on workplace violence. NIOSH collects data on reports of violence against nurses in order to aid in further prevention efforts and to develop training programs and new policies aimed at increasing safety measures for nurses and other healthcare workers (CDC, 2014e).

Mental Health Safety

Caring for others is a hallmark of the nursing profession. As a helping profession, nursing involves significant responsibility

for the well-being of others on many levels in addition to working in a highly stressful environment. Prolonged response to the many nursing work stressors mentioned at the beginning of this exemplar can lead not only to fatigue and distress but also to physical, mental, and emotional depletion, often referred to as **job burnout** or **compassion fatigue**. Nurses who experience compassion fatigue also experience less satisfaction from their work and are less engaged with their patients. The quality of their performance and interactions is affected.

It is essential for nurses to take care of their own physical and emotional selves so they can be physically, mentally, and emotionally prepared to care for their patients. Nurses need to look at themselves and recognize where stressors are coming from and think about what they can do about them to reduce stress and strain. Taking care of their bodies will support having healthy immune systems to avoid frequent bouts of sickness and disease. Nurses need to develop balance with lifestyle activities such as work and play, relaxation and activity, exercise and rest/sleep, aloneness and socializing, hobbies and family, and self and others. They can renew their spiritual selves, have fun, and decompress by appropriately expressing their thoughts and feeling their emotions. There is a need to refresh support systems at work, at home, and with others. Nurses can reaffirm all the reasons they went into nursing to care for others and make a difference for them. They can learn to say “No” at appropriate times to avoid extra demands on time and sometimes remember that they have a sense of humor.

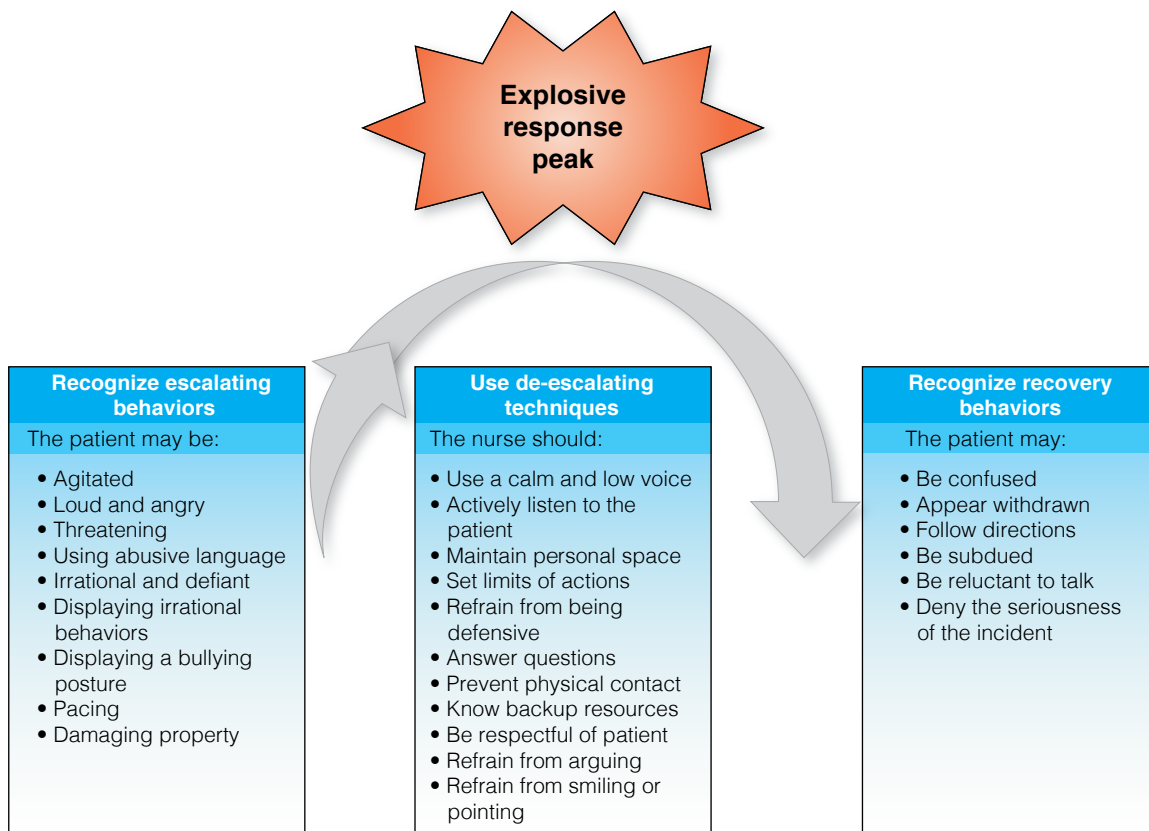

Figure 51-14 » The process of de-escalating aggressive behaviors includes three stages: recognizing escalating behaviors, using de-escalating techniques, and recognizing recovery behaviors.

Healthcare facilities can and should take actions to support their nursing workforce. For example, they can invest in reduced nurse–patient ratios to lessen nurse work pressures. This would give nurses more time with patients and potentially improve patient outcomes and provide short periods of time for nurses to eat and refresh themselves. Workplace morale can be enhanced with appreciation and incentives for improvements made in patient safety and satisfaction. Debriefing teams can be developed to work with nurses and others after psychologically stressful situations occur. An employee assistance program can be started to help avoid compassion fatigue. When nurses are refreshed, recommitted to helping care for others, taking care of themselves, and physically and emotionally healthy, they will be able to withstand the challenges of nursing and once again enjoy helping their patients. They will again be able to provide safe, effective, and quality care for their patients.

Substance Abuse and Safety

In order for nurses to provide quality and safety for their patients, they must be able to withstand the many pressures of physical, mental, and emotional demands in the work environment and strains from their personal lives and families. Impaired nurses under the influence of alcohol or drugs will not be able to proficiently perform necessary procedures, make accurate decisions about their nursing responsibilities, or make necessary critical clinical judgments about patient care. Dysfunctional nurses in a clinical environment can mean more errors, injuries, and accidents. Patients needing their pain or sleep medications may remain in pain or unable to have restful sleep. This quickly becomes a high-priority safety hazard for patients and others.

Every board of nursing has substance abuse policies, procedures, and expectation guidelines about treatment, nursing license status, rehabilitation, peer nurse support groups, and conditions of returning to the nursing workforce. There may be legal involvement of federal drug enforcement agencies if controlled narcotic substances have been diverted, used, or sold to others. Employee assistance programs can support recovering nurses. Addiction is treatable, recovery is difficult but possible, and relapse can happen (for more information about substance abuse among nurses, see the module on Addiction).

Home Healthcare Nurses and Injuries

Providing home health nursing care can be just as challenging and rewarding as providing healthcare in a healthcare

facility. Unfortunately, it also can have many of the same safety hazards—for example, bloodborne and infectious pathogens, needlesticks, latex, chemical exposure, and patient handling. In addition to these, home healthcare nurses also contend with hostile animals, unhygienic and dangerous surroundings, and road travel to patients' homes. OSHA has many materials on safety available for healthcare workers on their website (CDC, 2015g).

Safety measures for the home health nurse begin with an assessment of the patient's home and neighborhood to identify potential risks. This assessment can be a part of the discharge planning and patient/family education to help create a safe environment for everyone. Ongoing safety training for nurses should include personal protection maneuvers, prevention of infectious disease, needlestick safety, minimizing latex allergic reactions, avoiding chemical exposure, and prevention of musculoskeletal injuries.

Common steps to follow to maintain safety for the home health nurse include:

- Being aware of immediate surroundings
- Using a GPS system or detailed map to know address locations
- Making home visits during daylight hours as possible
- Parking the car in a lighted area with minimal shrubs close by
- Avoiding setting personal items or supply bags on carpeted floor
- Using mechanical devices to assist in lifting and moving as available
- Using non-latex gloves and hand sanitizer
- Not leaving supplies or personal belongings visible in the car and locking doors
- Carrying extra personal protective equipment (PPE) supplies in car
- Waiting outside door if unrestrained animal poses a threat until pet is restrained
- Taking only necessary equipment and supplies inside home
- Anticipating homes that may not be cooled or heated and wearing appropriate clothing.

REVIEW Nurse Safety

RELATE Link the Concepts and Exemplars

Linking the exemplar on nurse safety with the concept of mobility:

1. Describe methods of helping a patient with multiple sclerosis to reposition without compromising the nurse's own musculoskeletal health.
2. Among nurses, what are some common causes of back injury in the workplace? What are some methods for decreasing the incidence of these injuries?

Linking the exemplar on nurse safety with the concept of communication:

3. During a home visit, a patient becomes verbally aggressive toward his nurse. What communication techniques should the nurse employ with this patient? Explain your answer.

Linking the exemplar on nurse safety with the concept of reproduction:

4. The new parent is trying to hold her newborn while eating breakfast. What are some potential safety problems with this situation? What should the nurse do?

5. As the nurse is making rounds on her patients, she notices that a newborn is being carried by the mother taking a short walk down the hallway. Is this a safety concern? Why or why not?

- Additional review materials

REFLECT Apply Your Knowledge

The nurse is inserting an intravenous (IV) access device into a patient's arm. The patient has advanced hepatitis C and has been admitted to the hospital because of hepatitis-induced liver failure. After inserting

the IV device, the nurse places the needle portion on the patient's bed so he can quickly secure infusion tubing to the IV port. When the patient moves her arm, the needle falls to the floor. Upon retrieving the needle, the nurse accidentally punctures himself. Once the needle has punctured his skin, he immediately stops what he is doing and washes the injury site thoroughly with warm soapy water.

1. After cleansing the injury site, what should be the nurse's next action?
2. Could the nurse have done anything differently in this situation to avoid the injury? Explain your answer.
3. Explain the postexposure follow-up guidelines for individuals who sustain needlestick injuries.

Appendix B

Diagnostic Values and Laboratory Tests

Acetaminophen (Serum)

Reference Values

Adult: *Therapeutic*: 5–20 mcg/mL, 31–124 µmol/L (SI units). *Toxic*: greater than 50 mcg/mL, 305 µmol/L (SI units), greater than 200 mcg/mL possible hepatotoxicity.
Child: *Therapeutic*: Same as adult. *Toxic*: Similar to adult.

Purpose

- To indicate if the acetaminophen dosage is within the therapeutic range.
- N-Acetylcysteine is the antidote for acetaminophen.

Acetone, Ketone Bodies (Serum or Plasma)

Reference Values

Adult: *Acetone*: Semiquantitative: Negative (less than 1 mg/dL); quantitative: 0.3–2.0 mg/dL, 51.63–344.0 µmol/L (SI units). *Ketones*: 0.5–4 mg/dL.
Child: *Newborn to 1 Week*: Slightly higher than adult. *Over 1 Week*: Same as adult.

Purpose

- To monitor acidosis caused by uncontrolled diabetes or starvation.

Acetylcholine Receptor Antibody (AChR) (Serum)

Reference Values

Less than 0.02 to less than 0.03 nmol/L or negative.

Purpose

- To diagnose and monitor effects of drug therapy for myasthenia gravis.

Acid Phosphatase (ACP) (Serum)

Reference Values

Adult: Less than 2.6 ng/mL; 0–5 unit/L range, varies according to the method used; 0.2–13 international unit/L (SI units).

Purpose

- Used with other diagnostic tests to diagnose prostate cancer or BPH.

Adenovirus Antibody (Serum)

Reference Values

Adult and Child: Negative. *Positive*: Fourfold titer increase.

Purpose

- To identify the cause of upper respiratory tract disease and pharyngitis.

Adrenocorticotrophic Hormone (ACTH) (Plasma)

Reference Values

7 a.m. to 10 a.m.: 8–80 pg/mL; 8–80 ng/L (SI units); highest levels occur in early morning.
4 p.m.: 5–50 pg/mL; 5–50 ng/L (SI units).
10 p.m. to Midnight: Less than 10 pg/mL; lowest levels occur at bedtime.

Purpose

- To assess for adrenal or pituitary hypofunction.

Alanine Aminotransferase (ALT) (Serum)

Reference Values

Adult: 10–35 unit/L; 4–36 unit/L at 37°C (SI units). *Male*: Levels may be slightly higher.
Child: *Infant*: Could be twice as high as adult. *Child*: Similar to adult.
Older Adult: Slightly higher than adult.

Description

Alanine aminotransferase (ALT)/serum glutamic pyruvic transaminase (SGPT) is an enzyme found primarily in the liver cells and is effective in diagnosing hepatocellular destruction. It is also found in small amounts in the heart, kidney, and skeletal muscle.

B-2 Appendix B Diagnostic Values and Laboratory Tests

Serum ALT levels can be higher than levels of its sister transferase (transaminase), aspartate aminotransferase (AST)/serum glutamic oxaloacetic transaminase (SGOT), in cases of acute hepatitis and liver damage from drugs and chemicals. With its serum levels reaching to 200–4,000 unit/L, ALT is used for differentiating between jaundice caused by liver disease and hemolytic jaundice. With jaundice, the serum ALT levels of liver origin can be higher than 300 units; from causes outside the liver, the levels can be less than 300 units. Serum ALT levels usually elevate increase before jaundice appears.

ALT/SGPT levels are frequently compared with AST/SGOT levels for diagnostic purposes. ALT is increased more markedly than AST in liver necrosis and acute hepatitis, while whereas AST is more markedly increased in myocardial necrosis (acute myocardial infarction), cirrhosis, cancer of the liver, chronic hepatitis, and liver congestion. ALT levels are normal or slightly elevated in myocardial necrosis. The ALT levels return more slowly to normal range than AST levels in liver conditions.

Purpose

- To detect liver disorders.

Clinical Problems

Decreased Level: Exercise. *Drug Influence:* Salicylates.

Increased Level: *Highest Increase:* Acute (viral) hepatitis, necrosis of the liver (drug or chemical toxicity). *Slight or Moderate Increase:* Cirrhosis, cancer of the liver, heart failure (HF), acute alcohol intoxication. *Drug Influence:* Antibiotics (carbenicillin, clindamycin, erythromycin, gentamicin, lincomycin, mithramycin, spectinomycin, tetracycline), narcotics (meperidine [Demerol], morphine, codeine), antihypertensives (methyldopa, guanethidine), digitalis preparations, indomethacin (Indocin), salicylates, rifampin, flurazepam (Dalmane), propranolol (Inderal), oral contraceptives (progestin-estrogen), lead, heparin.

Albumin (Serum)

Reference Values

Adult: 3.5–5.0 g/dL; 52–68% of total protein.

Child: *Newborn:* 2.9–5.4 g/dL. *Infant:* 4.4–5.4 g/dL. *Child:* 4.0–5.8 g/dL.

Description

Albumin, a component of proteins, makes up more than half of plasma proteins. Albumin is synthesized by the liver. It increases osmotic pressure (oncotic pressure), which is necessary for maintaining the vascular fluid. A decrease in serum albumin will cause fluid to shift from within the vessels to the tissues, resulting in edema.

Purpose

- To detect an albumin deficit.

Alcohol (Ethyl or Ethanol) (Serum or Plasma)

Reference Values

No Alcohol: 0%. *No Significant Alcohol Influence:* Less than 0.05% or 50 mg/dL. *Alcohol Influence Present:* 0.05–0.10% or 50–100 mg/dL. *Reaction Time Affected:* 0.10–0.15% or 100–150 mg/dL. *Indicative of Alcohol Intoxication:* Greater than 0.15% or greater than 150 mg/dL. *Severe Alcohol Intoxication:* Greater than 0.25% or 250 mg/dL. *Comatose:* Greater than 0.30% or 300 mg/dL. *Fatal:* Greater than 0.40% or 400 mg/dL.

Purpose

- To detect the percentage of alcohol in the bloodstream.

Aldolase (ALD) (Serum)

Reference Values

Adult: Less than 6 unit/L, 3–8 unit/dL (Sibley-Lehninger), 22–59 milliunit/L at 37°C (SI units).

Child: *Infant:* 12–24 unit/dL (4 times). *Child:* 6–16 unit/dL (2 times).

Description

Aldolase is an enzyme present most abundantly in the skeletal and cardiac muscles. This enzyme is used to monitor skeletal muscle diseases such as muscular dystrophy, dermatomyositis, and trichinosis. It is not elevated in muscle disease of neural origin, such as multiple sclerosis, poliomyelitis, and myasthenia gravis.

Serum aldolase is helpful in diagnosing early cases of Duchenne muscular dystrophy before clinical symptoms appear. Progressive muscular dystrophy may cause elevated serum aldolase levels 10–15 times greater than normal. In late stages of muscular dystrophy, the enzyme level may return to normal or below normal. Serum aldolase is not the most effective diagnostic test for myocardial infarction (MI), because there is only a slight rise. Following an acute MI, it peaks (2 times its normal level) in 24 hours and returns to normal in 4–7 days.

Purpose

- To aid in the diagnosis of skeletal muscle diseases.

Aldosterone (Serum)

Reference Values

Adult: *Supine Position:* Less than 16 ng/dL. *Sitting position:* 4–30 ng/dL.

Child (3–11 years): 5–70 ng/dL; (11–16 years): 5–50 ng/dL.

Pregnancy: 2–3 times higher than adult.

Description

Aldosterone is the most potent of all mineralocorticoids produced by the adrenal cortex. This hormone responds to various

changes in the body. When sodium loss and water loss occur, aldosterone is secreted to reestablish sodium and water balance. Renin promotes aldosterone secretion, which causes more sodium and water to be retained and body fluid to be increased. Stress will increase aldosterone secretion. Hypernatremia (serum sodium excess) inhibits aldosterone secretion.

Serum aldosterone is not the most reliable test, because fluctuations can be caused by various influences. If the patient is in a supine position, serum aldosterone will be lower than if he or she were in a sitting or standing position. A 24-hour urine test is considered more reliable than a random serum aldosterone collection. Several serum aldosterone levels may be requested.

Purpose

- To detect deficit or excess of aldosterone.
- To determine overhydration.

Aldosterone (Urine)

Reference Values

Adult: 6–25 mcg/24 hours

Purpose

- See Aldosterone (serum).

Alkaline Phosphatase (ALP) with Isoenzyme (Serum)

Reference Values

Adult: 42–136 unit/L; ALP₁: 20–130 unit/L; ALP₂: 20–120 unit/L.

Child: *Infant and Child (0–12 Years)*: 40–115 unit/L. *Older Child (13–18 Years)*: 50–230 unit/L.

Older Adult: Slightly higher than adult.

Description

Alkaline phosphatase (ALP) is an enzyme produced mainly in the liver and bone; it is also derived from the intestine, kidney, and placenta. The ALP test is useful for determining liver and bone diseases. In cases of mild liver cell damage, the ALP level may be only slightly elevated, but it could be markedly elevated in acute liver disease. Once the acute phase is over, the serum level will promptly decrease, whereas the serum bilirubin will remain increased. For determining liver dysfunction, several laboratory tests are performed (i.e., bilirubin, leucine aminopeptidase [LAP], 5'-nucleotidase [5'-NT], and gamma-glutamyl transpeptidase [GGTP]).

With bone disorders, the ALP level is increased because of abnormal osteoblastic activity (bone cell production). In children it is not abnormal to find high levels of ALP before and during puberty because of bone growth.

Isoenzymes of ALP are used to distinguish between liver and bone diseases, ALP₁ indicating disease of liver origin, and ALP₂, bone origin.

Purposes

- To determine the presence of a liver or bone disorder.
- To compare ALP results with other laboratory tests for confirmation of a liver or bone disorder.

Alpha-Fetoprotein (AFP) (Serum and Amniotic Fluid)

Reference Values

Nonpregnancy: Less than 15 ng/mL.

Pregnancy:

Serum		Amniotic Fluid	
Weeks of Gestation	ng/mL	Weeks of Gestation	ng/mL
8–12	0–39	14	11–32
13	6–31	15	5.5–31
14	7–50	16	5.7–31.5
15	7–60	17	3.8–32.5
16	10–72	18	3.6–28
17	11–90	19	3.7–24.5
18	14–94	20	2.2–15
19	24–112	21	3.8–18
20	31–122		
21	19–124		

Description

Serum alpha-fetoprotein (AFP), a screening test, is usually done between 16 and 20 weeks' gestation to determine the probability of twins, or to detect low birth weight or serious birth defects, such as open neural-tube defect. If a high serum AFP level occurs, the test should be repeated 1 week later. Ultrasound and amniocentesis may be performed to confirm elevated serum levels and to diagnose neural-tube defects in the fetus.

Serum alpha-fetoprotein is also the tumor marker for testicular screening and testicular cancer.

Purpose

- To identify the probability of neural-tube defects, fetal death, or other anomalies in pregnancy (*see Clinical Problems*).

Clinical Problems

Decreased Level: Down syndrome, absence of pregnancy.

Increased Level: *Nonpregnant*: Cirrhosis of the liver (not liver metastasis), hepatitis, germ-cell tumor of gonads, such as testicular cancer, metastases to liver. *Pregnant*: Neural-tube defects (spina bifida, anencephaly, myelomeningocele), fetal death, fetal distress, Turner syndrome, other anomalies (duodenal atresia, tetralogy of Fallot, hydrocephalus, trisomy 13), severe Rh immunization.

Nursing Implications with Rationale

Alpha-Fetoprotein

- Explain that the test is for screening purposes. If the test is positive, genetic counseling might be necessary.
- Be supportive of individuals and family.

Patient Teaching

- Instruct the patient that it is essential to give the correct gestation date of the pregnancy, if known, to avoid a laboratory test error. Inform the patient that the test might be repeated in a week.
- If an ultrasound is performed, instruct the patient that it is usually done to confirm gestational age or to confirm the positive serum AFP and amniocentesis result(s).

Procedure

- Food and fluids are not restricted.
- Collect 5–7 mL of venous blood in a red-top tube. Avoid hemolysis.

Factors Affecting Laboratory Results

- Fetal blood contamination could cause an elevated amniotic AFP level.
- Inaccurate recording of gestation week could affect results.
- Multiple pregnancy or fetal death could cause a false-positive test.
- Hemolysis of blood sample could affect results.
- Body weight may be a factor (although not definitely confirmed). A heavier woman tends to have a lower serum AFP level.

Amino Acid (Urine)

Reference Values

Normal values are age dependent; 200 mg/24 h.

Purpose

- To screen for aminoacidurias.
- To detect inborn errors of metabolism.

Aminoglycosides (Serum)

Amikacin (Amikin), Gentamicin (Garamycin), Tobramycin (Nebcin)

Reference Values

Adult:

Therapeutic Range			
Drug Name	Peak (mcg/mL)	Trough (mcg/mL)	Toxic Level (mcg/mL)
Amikacin	15–30	<10	>35
Gentamicin	6–10	<1.5	>12
Kanamycin	15–30	1–4	>35
Netilmicin	0.5–10	<4	>16
Tobramycin	5–10	<2	>12

Child: Same as adult.

Purpose

- To assess patients receiving aminoglycosides for therapeutic effect.

Ammonia (Plasma)

Reference Values

Adult: 15–45 mcg/dL, 11–35 μ mol/L (SI units).

Child: *Newborn*: 64–107 mcg/dL. *Child*: 29–70 mcg/dL; 29–70 μ mol/L (SI units).

Description

Ammonia, a by-product of protein metabolism, is formed from the bacterial action in the intestine and from metabolizing tissues. Most of the ammonia is absorbed into the portal circulation and is converted in the liver to urea. With severe liver decompensation or when blood flow to the liver is altered, the plasma ammonia level remains elevated.

Elevated plasma ammonia is best correlated with hepatic failure; however, other conditions that interfere with liver function (heart failure, acidosis) may cause a temporary elevation of plasma ammonia.

Purpose

- To detect a liver disorder.

Amniotic Fluid Analysis

Amniocentesis, Amnioscopy

Normal Findings

Clear amniotic fluid, no chromosomal or neural tube abnormalities.

Description

Amniotic fluid analysis is useful for detecting chromosomal abnormalities, such as Down syndrome or mongolism (trisomy 21); neural-tube defects (spina bifida); sex-linked disorders, such as hemophilia; and for determining fetal maturity. The amniotic fluid is obtained by amniocentesis. This procedure involves the insertion of a needle into the suprapubic area after the fetus has been located and manually elevated and the aspiration of 5–15 mL of amniotic fluid. Ultrasound may be used to locate the placenta and to determine fetal position so that needle contact can be avoided. Amniocentesis is performed during the 14th to 16th weeks of pregnancy. It usually is not done before the 14th week because of the insufficient amount of amniotic fluid or after the 16th week if a therapeutic abortion might be suggested.

Analyses of the amniotic fluid may also include color, bilirubin (present in the fluid until the 28th week but absent at full term), meconium (present during stress—e.g., in breech presentation), creatinine, lecithin/sphingomyelin (L/S) ratio (a decreased ratio can indicate respiratory distress syndrome), glucose, lipids, and alpha-fetoprotein (AFP).

Amnioscopy involves insertion of a fiberoptic lighted instrument (amnioscope) into the cervical canal to visualize the amniotic fluid. The color of the amniotic fluid can indicate fetal hypoxia. This test is normally performed close to full term, because it requires cervical dilation. Because there

Nursing Implications with Rationale Amniotic Fluid Analysis

Pretest

- Recognize when amniocentesis for amniotic fluid analysis is indicated (i.e., with a familial history of sex-linked, genetic, or chromosomal disorders; with a history of previous miscarriages; and in advanced maternal age [greater than 35 years old]). It is not a screening test.
- Be sure that the patient urinates before the test and that the consent form is signed.
- Be supportive of the woman and her partner. Be a good listener. Allow them time to ask questions and to express any concerns. Refer questions you cannot answer to the appropriate health professionals.

Patient Teaching

- Inform the patient that normal results do not guarantee a normal infant, nor do they always predict gender correctly. The healthcare provider should tell the woman of potential risks, such as premature labor, spontaneous abortion, infection, and fetal or placental bleeding from the needle. These complications rarely occur, but the woman should be told of the risk factors.
- Instruct the patient to notify the healthcare provider immediately of any of the following: bleeding or leaking fluid from the vagina, abdominal pain or cramping, chills and fever, or lack of fetal movement.
- Encourage the woman and her partner to seek genetic counseling, especially if a chromosomal abnormality has been determined. Usually the final decision about terminating a pregnancy rests with the pregnant woman and her partner.

is a risk of rupturing the amniotic membrane and of intra-uterine infection, the test is rarely performed.

Purpose

- To detect chromosomal abnormalities, neural tube defects, and sex-linked disorders.
- To determine fetal maturity.

Foam Stability Test

This test determines if surfactant from mature fetal lungs is present in the amniotic fluid. When the test tube of amniotic fluid is shaken, bubbles appear around the surface if adequate amounts of surfactant are present.

Factors Affecting Diagnostic Results

- A traumatic amniocentesis tap may produce blood in the amniotic fluid.

Amylase (Urine)

Reference Values

Adult: 6.5–48 unit/h (SI units).

Purpose

- See Amylase (serum).

Amylase with Isoenzymes (Serum) Reference Values

Adult: 60–160 Somogyi unit/dL, 30–170 unit/L (SI units).

Pregnancy: Slightly increased.

Child: Not usually done.

Older Adult: Slightly higher than adult.

Serum Isoenzymes: *S* (salivary) type: 45–70%. *P* (pancreatic) type: 30–55%. Values may differ with method used.

Description

Amylase is an enzyme that is derived from the pancreas, the salivary glands, and the liver. Its function is to change starch to sugar. In acute pancreatitis, serum amylase is increased to twice its normal level. Its level begins to increase 2–12 hours after onset, peaks in 20–30 hours, and returns to normal in 2–4 days. Acute pancreatitis is frequently associated with inflammation, severe pain, and necrosis caused by digestive enzymes (including amylase) escaping into the surrounding tissue.

Increased serum amylase can occur after abdominal surgery involving the gallbladder (stones or biliary duct) and stomach (partial gastrectomy). Following abdominal surgery, some surgeons order a routine serum amylase for 2 days to determine whether the pancreas has been injured.

The urine amylase level is helpful in determining the significance of a normal or slightly elevated serum amylase, especially when the patient has symptoms of pancreatitis. Amylase levels can also be obtained from abdominal fluid, ascitic fluid, pleural effusion, and saliva.

There are two types of amylase isoenzymes, P type (pancreatic origin) and S type (salivary origin). P-type elevation occurs more frequently in acute pancreatitis. Elevated S type can occur as a result of parotitis or of ovarian and bronchogenic tumors. Amylase isoenzymes are usually ordered to rule out a nonpancreatic source of the elevated serum amylase level. A pancreatic isoenzyme kit is commercially available.

Purpose

- To assist in the diagnosis of acute pancreatitis and other health problems.

Amyloid Beta Protein Precursor (CSF)

Alzheimer Disease Marker

Reference Values

Normal: >450 unit/L cerebrospinal fluid (CSF).

Normal Findings

Normal structure and patency of the blood vessels.

Description

Amyloid beta protein is present in the senile plaques within the brain. Amyloid can also be found in the meningeal blood vessels of patients with Alzheimer disease. This type of

B-6 Appendix B Diagnostic Values and Laboratory Tests

protein is believed to have neurotoxic effects on the brain cells. Although small amounts of amyloid can be found in the CSF of most healthy individuals, a higher value occurs in the CSF of patients with Alzheimer disease and a somewhat higher value than normal may occur in an older adult with senile dementia.

Purpose

- To aid in the diagnosis of Alzheimer disease.

Angiography (Angiogram)

Arteriography: Cardiac (*see Cardiac Catheterization*), Cerebral Angiography, Pulmonary Angiography, and Renal Angiography

Description

The terms *angiography* (examination of the blood vessels) and *arteriography* (examination of the arteries) are used

interchangeably. A catheter is inserted into the femoral, brachial, subclavian, or carotid artery, and a contrast dye is injected to allow visualization of the blood vessels. Normally the patient feels a warm, flushed sensation as the dye is injected. Angiographies are useful for evaluating patency of blood vessels and for identifying abnormal vascularization resulting from neoplasms (tumors). This test may be indicated when computed tomography or radionuclide scanning suggests vascular abnormalities.

An embolus due to catheter clot formation is the most dangerous complication of angiography. Other complications include puncturing the site causing hematoma and/or hemorrhage, contrast media reactions, and infection.

Cerebral Angiography

Any of the three arteries (femoral, brachial, or carotid) can be used for access. The dye will outline the carotid artery, vertebral artery, large blood vessels of the circle of Willis, and small cerebral arterial branches.

Nursing Implications with Rationale Angiography

Pretest

- Obtain a patient history of hypersensitivity to iodine, seafood, or contrast dye from other x-ray procedures (e.g., intravenous pyelography [IVP]). The healthcare provider should also know if the patient is highly sensitive to other substances. Skin testing could be done before the test, or prophylactic medications (i.e., steroids, antihistamines) may be given prior to and/or following the test.
- Record baseline vital signs.
- Give a laxative or cleansing enema, if ordered. Explain to the patient that it will cleanse the lower intestinal tract, allowing better visualization.
- Have the patient void, wear a gown, and remove dentures.
- Administer premedications (sedative and narcotic analgesic) as ordered. Check that the consent form has been signed before giving premedications. The patient should be in bed with the bed sides up after the premedications are given.
- Encourage the patient to ask questions. This test can be frightening to patients, and they will need time to express any concerns.
- Assess for vasovagal reaction (common complication—i.e., decreased pulse rate and blood pressure [BP], cold and clammy skin). Give IV fluids and atropine IV. This reaction lasts about 15–20 minutes.

Patient Teaching

- Explain the procedure to the patient (*see Description, Procedure*). Inform the patient that the radiologist, surgeon, or healthcare provider will inject a contrast dye into an artery at the groin, elbow, or neck. The area will be numbed, and a catheter will be inserted and threaded with the guidance of fluoroscopy to the appropriate site.
- Inform the patient that when the dye is injected, he or she will most likely feel a warm, flushed sensation that should last for a minute or two. Explain to the patient that the test should not cause pain but can cause some periodic discomfort during the procedure.

Posttest

- Apply pressure on the injection site for 5–10 minutes or longer (venous access) or 30 minutes or longer (arterial access) until

bleeding has stopped. Check the injection site for bleeding when taking vital signs.

- Monitor vital signs as ordered, such as every 15 minutes for the first hour, every 30 minutes for the next 2 hours, and then every hour for the next 4 hours, or until stable. The temperature should be taken every 4 hours for 24–48 hours or as ordered.
- Enforce bedrest for 5 hours for venous access or 6–8 hours for arterial access or as ordered. Activities should be restricted for a day.
- Assess the injection site for swelling and for hematoma.
- Check peripheral pulses in the extremities (i.e., dorsalis pedis, femoral, and radial). Absence or weakness in pulse volume should be reported immediately.
- Note the temperature and color of the extremity. Report changes (e.g., color—pale, pain in the extremity, especially distal to access site) to the healthcare provider immediately. Arterial occlusion to the extremity could occur.
- Apply cold compresses or an ice pack to the injection site for edema or pain, if ordered.
- Monitor electrocardiogram tracings, urine output, and IV fluids. IV fluids and cardiac monitoring may be discontinued after the angiography.
- Inform the patient that coughing usually is not abnormal following a pulmonary angiography.
- Assess for dysphagia and for respiratory distress if the carotid artery was used for cerebral angiography.
- Assess for weakness or numbness in an extremity, confusion, slurred speech, or visual changes following a cerebral angiography. These could be symptoms of a transient ischemic attack (TIA), known as a “small stroke.”
- Observe for a delayed allergic reaction to the contrast dye (i.e., tachycardia, dyspnea, skin rash, urticaria [hives], decreasing systolic BP, and decreased urine output).
- Be supportive of the patient and his or her family. Answer questions, and explain your nursing implications.

Pulmonary Angiography

The catheter is inserted into the brachial artery (in the arm) or the femoral artery and is threaded to the pulmonary artery. The dye is injected for visualizing pulmonary vessels. During the test, the patient should be monitored for cardiac dysrhythmias.

Renal Angiography

The catheter is inserted into the femoral artery and is passed upward through the iliac artery and the aorta to the renal artery. This test permits visualization of the renal vessels and the parenchyma. An aortogram is sometimes made with real angiography to detect any vessel abnormality and to show the relationship of the renal arteries to the aorta.

Purposes

- To detect aneurysms, thrombosis, emboli, space-occupying lesions, stenosis, plaques.
- To evaluate cerebral, pulmonary, and renal blood flow.

Type of Angiography	Indications/Purposes
Cerebral	<ul style="list-style-type: none"> ■ To detect cerebrovascular aneurysm; cerebral thrombosis; hematomas; tumors from increased vascularization; cerebral plaques or spasm; cerebral fistula. ■ To determine cerebral blood flow, cause of increased intracranial pressure (↑ ICP).
Pulmonary	<ul style="list-style-type: none"> ■ To detect pulmonary embolism; tumors; aneurysms; congenital defects; vascular changes associated with emphysema, blebs, and bullae; heart abnormality. ■ To evaluate pulmonary circulation.
Renal	<ul style="list-style-type: none"> ■ To detect renal artery stenosis; renal thrombus or embolus; space-occupying lesions (i.e., tumors, cysts); aneurysms. ■ To determine the causative factor of hypertension, cause of renal failure. ■ To evaluate renal circulation.

Procedure

All Angiographies

- A consent form should be signed by the patient or a designated family member.
- The patient should be NPO for 8–12 hours before the angiogram. Anticoagulants (heparin) are usually discontinued.
- Record vital signs. Have patient void before the test.
- Dentures and metallic objects should be removed before the test.
- The access site should be shaved.
- Premedications (i.e., a sedative or narcotic analgesic), if ordered, are administered an hour before the test. If the patient has a history of severe allergic reactions to various substances or drugs, the healthcare provider may order steroids or antihistamines before and after the procedure as a prophylactic measure.
- Intravenous (IV) fluids may be started before the procedure so that emergency drugs, if needed, may be administered.

- The patient lies in a supine position on an x-ray table. A local anesthetic is administered to the injection incisional site.
- The test takes approximately 1–2 hours.

Renal

A laxative or cleansing enema is usually ordered the evening before the test.

Pulmonary

Electrocardiography electrodes are attached to the patient's chest for cardiac monitoring (tracings of heart activity) during the angiography. Pulmonary pressures are recorded, and blood samples are obtained before the contrast dye is injected.

Factors Affecting Diagnostic Results

- Feces and gas can distort or decrease the visualization of the kidneys.
- Barium sulfate from a recent barium study can interfere with the test results.
- Movement during the filming can distort the x-ray picture.

Angiotensin-converting Enzyme (ACE) (Serum)

Reference Values

Adult Older Than 20 Years: 8–67 unit/L.

Child and Adult Younger Than 20 Years: Test is *not* performed because they normally have elevated ACE levels.

Description

Angiotensin-converting enzyme (ACE) is found primarily in the lung epithelial cells and to a lesser extent in blood vessels and renal cells. The purpose of ACE is to regulate arterial blood pressure by converting angiotensin I to the vasoconstrictor angiotensin II, which increases blood pressure and stimulates the adrenal cortex to release aldosterone (sodium-retaining hormone).

This test should not be performed for patients who are under 20 years of age because they normally have elevated ACE levels. Approximately 5% of the population has an elevated ACE level.

Seventy to 90% of patients with active sarcoidosis have elevated serum ACE levels. Other conditions that have elevated ACE levels include Gaucher disease (disorder of fat metabolism), leprosy, alcoholic cirrhosis, active histoplasmosis, tuberculosis, pulmonary embolism, hyperthyroidism, and Hodgkin disease. This test has little value for diagnosing hypertension.

Purpose

- To assist in the diagnosis and assessment of severity of various health problems.

Anion Gap

Reference Values

Adult: 10–17 mEq/L (values differ from 7 to 20 mEq/L).

Description

The anion gap is the difference between electrolytes, the positive ions (cations) sodium and potassium, and the negative ions (anions) chloride and bicarbonate (serum CO₂) to determine if an acid–base imbalance is present. Unmeasured anions in the serum such as phosphates, sulfates, lactates, ketone bodies, and other organic acids contribute to metabolic acid–base imbalances (metabolic acidosis and alkalosis). Actually, the difference between the milliequivalents of cations and anions is referred to as the *anion gap*.

Serum levels of the cations sodium and potassium and the anions chloride and bicarbonate are applied to the formula:

$$\text{Anion gap} = (\text{sodium} + \text{potassium}) - (\text{chloride} + \text{HCO}_3 [\text{bicarbonate}])$$

An elevated anion gap (greater than 17 mEq/L) indicates metabolic acidosis; a decreased anion gap (less than 10 mEq/L) indicates metabolic alkalosis.

Purpose

- To determine the presence of acidosis.

Antibiotic Susceptibility (Sensitivity)

Reference Values

Adult: Organism is sensitive or intermediate or resistant to antibiotics.

Child: Same as adult.

Description

It is important to identify not only the organism responsible for the infection but also the antibiotic(s) that will inhibit the growth of the bacteria. The healthcare provider orders a culture and sensitivity test (C & S) when a wound infection, urinary tract infection, or other type of infected secretion is suspected. The choice of antibiotic depends on the pathogenic organism and its susceptibility to the antibiotics.

Purpose

- To check the effectiveness of selected antibiotics on a specific bacteria from a culture.

Anticardiolipin Antibodies (ACA) (Serum)

Reference Value

Negative.

Description

Anticardiolipin antibodies (ACA) are autoantibodies found in some patients with systemic lupus erythematosus (SLE). They occur in 45% of patients with SLE and less than 7% of patients without SLE. These antibodies were originally found in patients with SLE and were called

lupus anticoagulants (LA). Later it was determined that these antibodies did not act as anticoagulants and that they were found in patients with health problems other than lupus. ACA and LA are members of the antiphospholipid (APA) family of immunoglobulins active against phospholipids. ACA may also be present in patients having thrombocytopenia, spontaneous or recurrent thrombosis, or fetal loss.

Purpose

- To support the diagnosis of SLE.
- To detect ACA syndrome in patients with other health problems.

Anticonvulsants (Blood, Serum, Plasma)

Reference Values

Adult:

Drug Name	Therapeutic Range	
	mcg/mL	μmol/L
Carbamazepine	4–12	16.9–50.8
(Child)	(Same as adult)	
Ethosuximide	40–100	283–708
(Child)	(2–4 per 1 mg/kg/day)	
Phenytoin	10–20	39.6–79.3
Primidone	5–12	23–55
(Child <5 years)	(7–10)	(30–45)
Valproic acid	50–100	347–693
(Child)	(Same as adult)	
	Toxic Level	
	mcg/mL	μmol/L
Carbamazepine	>12–15	>50.8–69
(Child)	(Same as adult)	
Ethosuximide	>100	>708
(Child)	(Same as adult or higher)	
Phenytoin	>20	>79.3
Primidone	>12–15	>55–69
(Child <5 years)	(>12)	(>55)
Valproic acid	>100	>693
(Child)	(Same as adult)	

Purpose

- To monitor specific anticonvulsant serum levels.
- To detect the toxic level of a specific anticonvulsant.

Antidepressants (Tricyclics) (Serum)

Amitriptyline, Desipramine, Doxepin, Imipramine, Nortriptyline

Reference Values

Adult:

Drug Name	Therapeutic Range (ng/mL)	Toxic Level (ng/mL)
Amitriptyline HCl (Elavil)	75–225	>500
Desipramine HCl (Norpramin)	125–300	>500
Doxepin HCl (Sinequan)	150–300	>500
Imipramine HCl (Tofranil)	150–300	>500
Nortriptyline HCl (Aventyl)	75–150	>300

Antidiuretic Hormone (ADH) (Plasma) Vasopressor

Reference Values

Adult: 1–5 pg/mL; 1–5 ng/L.

Description

Antidiuretic hormone (ADH) is produced by the hypothalamus and stored in the posterior pituitary gland (neurohypophysis). The primary function of ADH is in water reabsorption from the distal renal tubules in response to the serum osmolality. *Antidiuretic* means “against diuresis.” More ADH is secreted from the posterior pituitary gland when the serum osmolality is increased to greater than 295 mOsm/kg (concentrated body fluids). More water reabsorption occurs, which dilutes the body fluid. When the serum osmolality is decreased to greater than 280 mOsm/kg, less ADH is secreted, and thus more water is excreted via the kidneys.

Syndrome (secretion) of inappropriate ADH (SIADH) is an excess secretion of ADH that is not influenced by the serum osmolality level. SIADH causes excess water retention. Stress, surgery, pain, and certain drugs (narcotics, anesthetics) contribute to SIADH.

Purpose

- To detect a deficit or excess in ADH secretion.
- To identify the presence of body fluid deficit or excess.

Antinuclear Antibodies (ANA) (Serum)

Anti-DNA Antibody, Anti-DNP Antibody

Reference Values

Adult: Negative at 1:20 dilution.

Description

ANAs are immunoglobulins (IgM, IgG, IgA) that react with the nuclear part of leukocytes. They form antibodies against deoxyribonucleic acid (DNA), ribonucleic acid (RNA), and others. Two ANAs, anti-DNA and anti-D-nucleoprotein (Anti-DNP), are almost always present with systemic lupus erythematosus (SLE). Anti-DNA will fluctuate according to

the disease process, with remission, and with exacerbation. It is normally present (95%) in lupus nephritis.

The total ANA level can also be elevated in scleroderma, rheumatoid arthritis, cirrhosis, leukemia, infectious mononucleosis, and malignancy. For diagnosing lupus, the ANA test should be compared with other tests for lupus.

Purpose

- To compare the ANA test with other laboratory tests for diagnosing SLE or other collagen diseases.

Antithrombin III (Plasma) AT3, AT-III, Factor XA Inhibitor

Reference Values

75–135% of normal/average.

Description

Antithrombin III (AT-III) is suggested to evaluate patients who have a hypercoagulable state and especially for patients with a history of thromboembolic disease. Some patients have a genetic deficiency of AT-III, which predisposes the patient to thrombus formation. Also patients who are deficient in AT-III may be resistant to heparin and would require a larger dose of an anticoagulant. Usually heparin resistance does not occur unless the AT-III is less than 60%. Elevated AT-III levels may occur in patients with acute hepatitis and a deficiency in vitamin K.

Purpose

- To test for genetic deficiency of AT-III.
- To determine the effect of drugs on AT-III.

Arterial Blood Gases (ABGs) (Arterial Blood)

Reference Values

Adult: pH: 7.35–7.45; PaCO₂: 35–45 mmHg; PaO₂: 75–100 mmHg; SaO₂: Greater than 95%; SvO₂: Greater than 70%; HCO₃: 24–28 mEq/L; base excesses (BE): +2 to –2 mEq/L.

Child: pH: 7.36–7.44. Other measurements are same as adult.

Description

The basic components of ABGs include the pH, PaCO₂, PaO₂, SO₂, HCO₃, and BE. See the discussion in the Concept of Acid-Base Balance.

pH: The pH, the negative logarithm of the hydrogen ion concentration, determines the acidity or alkalinity of body fluids. A pH less than 7.35 indicates acidosis, either respiratory acidosis or metabolic acidosis. A pH greater than 7.45 indicates alkalosis, either respiratory or metabolic alkalosis.

PaCO₂: The partial pressure of carbon dioxide (PaCO₂) reflects the adequacy of alveolar ventilation. When alveolar damage has occurred, carbon dioxide (CO₂) cannot

B-10 Appendix B Diagnostic Values and Laboratory Tests

escape. Carbon dioxide combines with water to form carbonic acid ($\text{H}_2\text{O} + \text{CO}_2 = \text{H}_2\text{CO}_3$), causing an acidotic state. When the patient has alveolar hypoventilation, the PaCO_2 is elevated, and respiratory acidosis results. Chronic obstructive lung disease is a major cause of respiratory acidosis. When the patient has alveolar hyperventilation (blowing off CO_2 by rapid deep breathing), the PaCO_2 is decreased, and respiratory alkalosis results.

PaO_2 : The partial pressure of oxygen (PaO_2) determines the amount of oxygen available to bind with hemoglobin. The pH affects the combining power of oxygen and hemoglobin, and with a low pH, there will be less oxygen in the hemoglobin. The PaO_2 is decreased in respiratory diseases, such as emphysema, pneumonia, and pulmonary edema; in the presence of abnormal hemoglobin (CO Hb, Meth Hb, Sulfa Hb); and in polycythemia.

SO_2 : The oxygen saturation (SO_2) is the percentage of oxygen in the blood that combines with hemoglobin. It is measured indirectly by calculation of the PaO_2 and pH or measured directly by co-oximetry. The combination of oxygen saturation, partial pressure of oxygen, and hemoglobin indicates tissue oxygenation.

HCO_3 and BE: Bicarbonate ion (HCO_3) is an alkaline substance that makes up over half of the total buffer base in the blood. When there is a deficit of bicarbonate and other bases or an increase in nonvolatile acid such as lactic acid, metabolic acidosis occurs. If a bicarbonate excess is present, then metabolic alkalosis results. The bicarbonate plays a very important role in maintaining a pH of 7.35 to 7.45.

The base excess (BE) value is frequently checked with the HCO_3 value. A base excess of less than -2 is acidosis and greater than $+2$ is alkalosis.

Acid–Base Imbalances

To determine the type of acid–base (A–B) imbalance, the pH, PaCO_2 , HCO_3 , and BE are checked. The PaCO_2 is a respiratory determinant, and the HCO_3 and BE are metabolic determinants. The PaCO_2 , HCO_3 , and BE values are compared to the pH. A pH of less than 7.35 is acidosis and one of greater than 7.45 is alkalosis.

1. If the pH is less than 7.35, the PaCO_2 is greater than 45 mmHg, and the HCO_3 and BE are normal, the A–B imbalance is respiratory acidosis.
2. If the pH is greater than 7.45, the PaCO_2 is less than 35 mmHg, and the HCO_3 and BE are normal, the A–B imbalance is respiratory alkalosis.
3. If the pH is less than 7.35, the PaCO_2 is normal, the HCO_3 and BE are less than 24 mEq/L and less than -2 , the A–B imbalance is metabolic acidosis.
4. If the pH is greater than 7.45, the PaCO_2 is normal, the HCO_3 and BE are greater than 28 mEq/L and greater than $+2$, the A–B imbalance is metabolic alkalosis.

Acid–Base Imbalance	pH	PaCO_2	HCO_3	BE
Respiratory acidosis	↓	↑	N	N
Respiratory alkalosis	↑	↓	N	N
Metabolic acidosis	↓	N	↓	↓
Metabolic alkalosis	↑	N	↑	↑

Purpose

- To assess disturbances of acid–base balance caused by a respiratory and/or metabolic disorder.

Clinical Problems

Respiratory Acidosis (pH less than 7.35; PaCO_2 greater than 45 mmHg): Chronic obstructive lung disease (emphysema, chronic bronchitis, severe asthma), acute respiratory distress syndrome (ARDS), Guillain-Barré syndrome, anesthesia, pneumonia. *Drug Influence:* Narcotics, sedatives

Respiratory Alkalosis (pH greater than 7.45; PaCO_2 less than 35 mmHg): Salicylate toxicity (early phase), anxiety, hysteria, tetany, strenuous exercise (swimming, running), fever, hyperthyroidism, delirium tremens, pulmonary embolism

Metabolic Acidosis (pH less than 7.35; HCO_3 less than 24 mEq/L): Diabetic ketoacidosis, severe diarrhea, starvation/malnutrition, shock, burns, kidney failure, acute myocardial infarction

Metabolic Alkalosis (pH greater than 7.45; HCO_3 greater than 28 mEq/L): Severe vomiting, gastric suction, peptic ulcer, potassium loss, excess administration of bicarbonate, hepatic failure, cystic fibrosis. *Drug Influence:* Sodium bicarbonate, sodium oxalate, potassium oxalate.

Factors Affecting Laboratory Results

- Improper handling of the blood sample, such as not using ice water, exposure of specimen to air, and not expelling all the heparin out of the collection syringe, causes inaccurate results.
- Hemolysis of the blood sample causes false results.
- Narcotics and sedatives can contribute to the respiratory acidotic state, and sodium bicarbonate could cause metabolic alkalosis.
- Inaccurate results can occur as a result of suctioning, changes in O_2 therapy, and ventilator use; exposure to carbon monoxide or nitrate; and blood transfusion.

Arthrography

Normal Findings

Knee: Normal medial meniscus

Shoulder: Bicipital tendon sheath, normal joint capsule, and intact subscapular bursa.

Description

Arthrography is an x-ray examination of a joint using air, contrast media, or both in the joint space.

Purpose

- To detect abnormalities of the cartilage and/or ligaments (e.g., tears)
- To visualize structures of the joint capsule.

Procedure

- Food and fluids are not restricted.
- Prepare the knee or shoulder area using aseptic technique.

- Local anesthetic is administered to puncture site.
- A needle is inserted into the joint space (e.g., knee), and synovial fluid is aspirated for synovial fluid analysis.
- Air and/or contrast medium is injected into the joint space, and x-rays are taken.
- The knee may be bandaged.

Arthroscopy

Normal Findings

Normal lining of the synovial membrane. Cartilage is smooth and white and ligaments and tendons are intact.

Purpose

- To diagnose meniscal, patellar, extrasynovial, and synovial diseases.
- To perform joint surgery.
- To monitor disease process or the effects of a medical or surgical therapeutic regimen.

Procedure

- A consent form should be signed.
- There is no food or fluid restriction for local anesthetic. NPO after midnight for spinal and general anesthesia.
- Local, spinal, or general anesthesia is used, depending on the purpose and procedure for the test.
- Ace bandage and/or tourniquet may be applied to decrease blood volume in the leg.
- The arthroscope is inserted into the interior joint for visualization, for draining fluid from the joint, for biopsy, or for surgery.
- A dressing is applied to the incision site of the affected joint.

Aspartate Aminotransferase (AST) (Serum)

Serum Glutamic Oxaloacetic Transaminase (SGOT)

Reference Values

Adult: *Average range:* 8–35 unit/L, 5–40 unit/mL (Frankel), 4–36 international unit/L, 15–50 unit/mL at 30°C (Karmen), 8–33 unit/L at 37°C (SI units). Female values may be slightly lower than those of males. Exercise tends to increase values (values can vary among institutions).

Child: *Newborn:* 4 times the normal level. *Child:* Similar to adults. *Older Adult:* Slightly higher than adults.

Description

Aspartate aminotransferase/serum glutamic oxaloacetic transaminase (AST/SGOT) is an enzyme found mainly in the heart muscle and liver, with moderate amounts in skeletal muscle, the kidneys, and the pancreas. Its concentration is low in the blood except when cellular injury has occurred, in which case large amounts are released into circulation.

High levels of serum AST are found following an acute myocardial infarction (MI) and liver damage. Six to 10 hours

after an acute MI, AST leaks out of the heart muscle and reaches its peak in 24–48 hours after the infarction. The serum AST level returns to normal 4–6 days later if there is no additional infarction. Serum AST is usually compared with other cardiac enzymes (creatine kinase [CK], lactate dehydrogenase [LDH], troponins).

In liver disease, the serum level increases by 10 times or more and remains elevated for a longer period of time.

Purpose

- To aid in the diagnosis of acute MI or liver damage.
- To compare AST results with CK, LDH, and troponins for diagnosing an acute MI.

Barbiturate (Blood)

Reference Values

Adult:

Barbiturate	Action	Therapeutic (mcg/mL)	Toxic (mcg/mL)
Secobarbital (Seconal)	Short acting	1–5	>8
Pentobarbital (Nembutal)	Short acting	1–5	>8
Amobarbital (Amytal)	Intermediate acting	5–14	>20
Phenobarbital	Long acting	10–30 20–40 (seizure control)	>60

Child: *Phenobarbital:* *Therapeutic:* 15–30 mcg/mL. *Toxic:* Greater than 35 mcg/mL.

Purpose

- To assess specific barbiturate serum level.

Barium Enema

Lower Gastrointestinal Test, X-Ray Examination of the Colon

Normal Findings

Adult: Normal filling, normal structure of the large colon.

Description

Barium sulfate (single contrast) or barium sulfate and air (double contrast or air contrast) is administered slowly through a rectal tube into the large colon. The filling process is monitored by fluoroscopy, and then x-rays are taken. The colon must be free of fecal material so that the barium will outline the large intestine to detect any disorders. The double-contrast technique (barium and air) is useful for identifying polyps.

The barium enema test is indicated for patients complaining of lower abdominal pain and cramps; blood, mucus, or pus in the stool; changes in bowel habits; and changes in stool formation. The test can be performed in a hospital, in a clinic, or at a private laboratory.

Purpose

- To detect the presence of polyps, an intestinal mass, diverticuli, an intestinal stricture/obstruction, or ulcerations.

Procedure

In most institutions the procedures for the barium enema are similar; however, they usually differ to some degree. Abdominal x-rays, ultrasound studies, radionuclide scans, and proctosigmoidoscopy should be done *before* the barium enema. It is important for the colon to be free of fecal material.

Prepreparation

- Some institutions request that the patient maintain a low-residue diet (tender meats, eggs, bread, clear soup, pureed bland vegetables and fruits, potatoes, and boiled milk) for 2–3 days before the test.
- Oral medications should not be given for 24 hours before the test, unless indicated by the healthcare provider. Narcotics and barbiturates could interfere with fecal elimination before and after the test.
- The patient should be on a clear-liquid diet for 18–24 hours before the test. This would include broth, ginger ale, cola, black coffee or tea with sugar only, gelatin, and syrup from canned fruit. Some institutions permit a white chicken sandwich (*no* butter, lettuce, or mayonnaise) or hard-boiled eggs and gelatin for lunch and dinner, then NPO after dinner.
- Encourage the patient to increase water and clear liquid intake 24 hours before the test to maintain adequate hydration.
- Prescribe laxatives (castor oil or magnesium citrate) to be taken the day before the test in the late afternoon or early evening (4 p.m. to 8 p.m.).
- A cleansing enema or laxative suppository such as bisacodyl (Dulcolax) may be given the evening before the test.
- Saline enemas (maximum three enemas) should be given early in the morning (6 a.m.) until the returned solution is clear. Some private laboratories have patients use bisacodyl suppositories in the morning instead of the enemas.
- Black coffee or tea is permitted 1 hour before the test. Some institutions permit dry toast.

Postpreparation

- The patient should expel the barium in the bathroom or bedpan immediately after the test.
- Fluid intake should be increased for hydration and to prevent constipation due to retained barium.
- A laxative, such as milk of magnesia or magnesium citrate, or an oil retention enema should be given to remove the barium from the colon. A laxative may need to be repeated the following day after the test.

Factors Affecting Diagnostic Results

- Inadequate bowel preparation with fecal material remaining in the colon could affect results.
- The use of barium sulfate in upper gastrointestinal and small-bowel studies 2–3 days before the barium enema test could affect the results.

Bilirubin (Indirect) (Serum)

Reference Values

Adult: 0.1–1.0 mg/dL, 1.7–17.1 μ mol/L (SI units).

Child: Same as adult.

Description

(See *Bilirubin [Total and Direct]*.)

Indirect-reacting or unconjugated bilirubin is protein bound and is associated with increased destruction of red blood cells (hemolysis).

Elevated indirect bilirubin can occur in autoimmune- or transfusion-induced hemolysis, in hemolytic processes caused by sickle cell disease, in pernicious anemia, and with malaria and septicemia. Internal hemorrhage into soft tissues and the body cavity can cause the bilirubin to rise in 5–6 hours. With certain clinical problems, heart failure, and severe liver damage, both indirect and direct bilirubin levels will increase. Indirect bilirubin frequently increases because the damaged liver cells cannot conjugate normal amounts, which leads to increased unconjugated bilirubin.

Nursing Implications with Rationale Barium Enema

- Review the written procedure for that institution. Explain the procedure to the patient. Procedures do differ from one institution to another. Usually the preparations for a barium enema have similarities (clear liquids, increased fluid intake, laxatives, and cleansing enemas). Fecal material in the large intestine (bowel or colon) should be completely eliminated.
- List the procedure step by step for the patient. Most private laboratories and hospitals have written preparation slips. The procedure may be sent to the patient at home.
- Emphasize the importance of following dietary restrictions and of bowel preparation. Adequate prepreparation is essential or the test may need to be repeated.
- Notify the healthcare provider if the patient has severe abdominal cramps and pain prior to the test. The barium enema test should not be performed if the patient has severe ulcerative colitis, suspected perforation, or tachycardia.

Patient Teaching

- Explain to the patient that he or she will be lying on a tilting x-ray table for positioning purposes to increase the barium flow into the colon. Explain that a technician will be with him or her and will explain each step of the procedure.
- Inform the patient that the test takes approximately 1/2 to 1 hour to complete. Tell the patient to take deep breaths through the mouth, which helps to decrease tension and to promote relaxation.
- Administer a laxative or cleansing enema after the test. Instruct the patient to check the color of the stools for 2–3 days. Stools may be light in color because of the barium sulfate. Absence of stool should be reported. Retention of barium sulfate after the test could cause obstruction and/or fecal impaction.

Levels of indirect serum bilirubin may increase in hemolytic disease, such as erythroblastosis fetalis, in newborns. The newborn's liver is immature, and when extremely high levels of bilirubin occur, irreversible neurologic damage, referred to as kernicterus, could result.

Purpose

- To detect the presence of unconjugated bilirubin due to hemolytic disease or liver disease.

Bilirubin (Total and Direct) (Serum)

Reference Values

Adult: *Total*: 0.1–1.2 mg/dL, 1.7–20.5 $\mu\text{mol/L}$ (SI units). *Direct (Conjugated)*: 0.1–0.3 mg/dL, 1.7–5.1 $\mu\text{mol/L}$ (SI units).

Child: *Newborn: Total*: 1–12 mg/dL, 17.1–205 $\mu\text{mol/L}$ (SI units). *Child*: 0.2–0.8 mg/dL.

Panic Level: 15 mg/dL.

Description

Bilirubin is formed from the breakdown of hemoglobin by the reticuloendothelial system and is carried in the plasma to the liver, where it is conjugated (directly) to form bilirubin diglucuronide and is excreted in the bile. The two forms of bilirubin in the body are conjugated, or direct reacting (soluble), and unconjugated, or indirect reacting (protein bound). If the total bilirubin is within normal range, direct and indirect bilirubin levels do not need to be analyzed. If one value of bilirubin is reported, it represents the total bilirubin.

Direct or conjugated bilirubin is frequently the result of obstructive jaundice, either extrahepatic (from stones or tumor) or intrahepatic in origin. Conjugated bilirubin cannot escape in the bile into the intestine and thus backs up and is absorbed into the bloodstream. Damaged liver cells cause a blockage of the bile sinusoid, increasing the serum level of direct bilirubin. With hepatitis and decompensated cirrhosis, both direct and indirect bilirubin may be elevated.

Jaundice is frequently present when serum bilirubin levels are greater than 3 mg/dL.

Purpose

- To monitor bilirubin levels associated with jaundice.
- To suggest the occurrence of a liver disorder.

Bilirubin and Bile (Urine)

Reference Values

Adult: *Negative*: 0.02 mg/dL.

Description

Bilirubin is not normally present in urine; however, a very small quantity could be present without being detected by routine test methods. Bilirubin is formed from the breakdown of hemoglobin and is transported to the liver, where it is conjugated and then excreted as bile. Conjugated or direct bilirubin is water soluble and is excreted in the urine when

there is an increased serum level. Unconjugated or indirect bilirubin is fat soluble and cannot be excreted in the urine.

Bilirubinuria (bilirubin in urine) indicates liver damage or biliary obstruction (e.g., stones), and a large amount has a characteristic dark-amber color. When the amber-colored urine is shaken, it produces a yellow foam. It can frequently be tested by the floor nurse with a dipstick or reagent tablet.

Purpose

- To compare with serum bilirubin level and liver enzyme tests to detect a liver disorder.

Biopsy (Bone Marrow, Breast, Endometrium, Kidney, Liver)

Normal Findings

Normal cells and tissue.

Description

Biopsy is the removal and examination of tissue from the body. Biopsies can be obtained by (1) aspiration by applying suction; (2) the brush method, using stiff bristles that scrape fragments of cells and tissue; (3) excision by surgical cutting at tissue site; (4) fine-needle or needle aspiration at tissue site with or without the guidance of ultrasound; (5) insertion of a needle through the skin; and (6) punch biopsy, using a punch-type instrument.

Biopsies are performed on various organs and body structures, such as bone marrow, breast, endometrium of the uterus, kidney, and liver. The methods used to obtain biopsy tissues from various organs may differ.

Purpose

- To identify abnormal tissue.
- To detect the presence of a disease process.

Bleeding Time (Blood)

Reference Values

Adult: *Ivy Method*: 1–9 minutes. *Panic Level*: >15 minutes. *Duke Method*: 1–3 minutes. SI units for the Ivy and Duke methods are the same. (Duke method is seldom performed.)

Description

Bleeding time is lengthened in thrombocytopenia (decreased platelet count, less than 50,000). The test is frequently performed when there is a history of bleeding (easy bruising), familial bleeding, or preoperative screening. The Ivy technique, in which the forearm is used for the incision, is the most popular method. Aspirin and anti-inflammatory medications can prolong the bleeding time.

Purpose

- To determine whether bleeding time is normal or prolonged.

Blood Urea Nitrogen (BUN) (Serum)

Reference Values

Adult: 5–25 mg/dL.

Child: *Newborn*: 3–12 mg/dL. *Infant*: 5–15 mg/dL. *Child*: 5–20 mg/dL.

Older Adult: Could be slightly higher than adult.

Description

Urea is formed as an end product of protein metabolism and is excreted by the kidneys. An elevated blood urea nitrogen (BUN) level could be an indication of dehydration, prerenal failure, or renal failure. Dehydration from vomiting, diarrhea, and/or inadequate fluid intake can cause an increase in the BUN (up to 35 mg/dL). With dehydration, the serum creatinine level would most likely be normal or high normal. Once the patient is hydrated, the BUN should return to normal; if it does not, prerenal or renal failure would be suspected. Nephrons (kidney cells) tend to decrease during the aging process, so older individuals may have a higher BUN. Digested blood from gastrointestinal (GI) bleeding is a source of protein and can cause the BUN to elevate. A low BUN value usually indicates overhydration (hypervolemia).

The **BUN/creatinine ratio** is a calculation with a reference value of 10:1 to 15:1. A decreased BUN/creatinine ratio occurs with malnutrition, liver disease, low-protein diet, excessive IV fluids, dialysis, or overhydration. An elevated BUN/creatinine ratio, greater than 15:1, is found in renal disease, inadequate renal perfusion, shock, dehydration, GI bleeding, and drugs such as steroids and tetracyclines. See next listing for more about the BUN/creatinine ratio.

Purpose

- To detect a renal disorder or dehydration.

Blood Urea Nitrogen/Creatinine Ratio (Serum)

Urea Nitrogen/Creatinine Ratio

Reference Values

Adult: 10:1 to 20:1 (BUN:creatinine). *Average*: 15:1.

Description

The BUN level can increase because of dehydration as well as renal dysfunction. The creatinine level does not increase with dehydration but definitely increases with renal dysfunction. This ratio test is more sensitive to the relationship of BUN to creatinine than separate tests of BUN and creatinine. However, liver function, dietary protein intake, and muscle mass may affect test results.

A decreased ratio can occur from acute renal tubular necrosis and low protein intake. The ratio may be increased because of reduced renal perfusion, glomerular disease, obstructive uropathy, or high protein intake.

Purpose

- To determine renal function.

Bone Densitometry

Bone Density (BD), Bone Mineral Density (BMD), Bone Absorptiometry

Normal Findings

Normal bone densitometry scan is determined according to the patient's age, gender, and height.

Normal

1 standard deviation below peak bone mass level.

Osteoporosis

Greater than 2.5 standard deviations below peak bone mass level (WHO standard).

Description

The bones are made up of minerals and protein. Bone mass peaks when an individual is in the mid-30s. After that, bone is lost at a rate somewhat greater than new bone is made. When a woman reaches menopause, bone loss accelerates to about 1–3% each year. After age 60, bone loss in women slows but it does not stop, and as she gets older, bone mass loss could be between 35% and 50%. The risk of bone fracture is greater in women than men. Men lose bone also; however, they do so at a lower rate than women: 3–5% per decade. Usually, men develop osteoporosis about a decade later than women.

A bone density test is designed to detect early osteoporosis by determining the density of bone mineral content. Patients who have a loss of bone mineral are readily prone to have fractures. The bones that are usually examined are the lumbar spine and the proximal hip (neck of the femur). Another bone site, the heel bone, can be evaluated according to the patient's symptoms.

The dual energy x-ray absorptiometry (DEXA) test measures bone mineral density and only exposes the patient to a minimal amount of radiation. Images from the detector/camera are computer analyzed to determine the bone mineral content. The computer can calculate the size and thickness of the bone.

Bronchography (Bronchogram)

Description

Normal Findings

Normal tracheobronchial structure.

Bronchography is an x-ray test to visualize the trachea, bronchi, and entire bronchial tree after a radiopaque iodine contrast liquid is injected through a catheter into the tracheobronchial space. The bronchi are coated with the contrast dye, and a series of x-rays is then taken. Bronchography may be done in conjunction with bronchoscopy.

Contraindications include pregnancy and hypersensitivity to anesthetics, iodine, or x-ray dyes.

Purpose

- To detect bronchial obstruction.

Procedure

- A consent form should be signed.
- The patient should be NPO for 6–8 hours before the test.

Nursing Implications with Rationale

Bronchoscopy

Pretest

- Explain the procedure to the patient. Explanation is important to help allay the patient's anxiety.
- Check that the consent form is signed and that the patient has voided before administering premedications. One of the drugs usually administered is atropine, which causes dryness of the mouth.
- Check that dentures, contact lenses, and jewelry have been removed.
- Obtain vital signs (VS), and prepare a VS flowchart. Record admission and pretest vital signs, which will serve as baseline VS.
- Advise the patient that the procedure takes about 1 hour.

Patient Teaching

- Instruct the patient to relax before and during the test. The premedications will aid in increasing relaxation and decreasing anxiety. Tell the patient the healthcare provider will inform her of how the procedure is progressing. Bronchoscopy usually is performed under local anesthesia but could be performed under general anesthesia. The patient should be told whether she will receive a local or a general anesthetic.
- Inform the patient that the drugs will make her feel sleepy and the mouth feel dry. The patient should remain in bed, and the bed sides should be up after premedications are given.
- Instruct the patient to practice breathing in and out through the nose with the mouth opened. This is important if the bronchoscope is inserted through the mouth.
- Encourage the patient to ask questions and give her time to express concerns. Inform the patient that there may be some discomfort but that the spray will help to decrease it. Inform the patient that she will receive adequate air exchange. Oxygen can be given through the side arm of the bronchoscope or rigid scope and by mask for fiberoptic scope.

- Inform the patient that she may experience hoarseness and/or a sore throat after the test.

Posttest

- Recognize the complications that can follow bronchoscopy (i.e., laryngeal edema, bronchospasm, pneumothorax, cardiac dysrhythmias, and bleeding from the biopsy site).
- Check VS until stable and as indicated.
- Elevate the head of the bed (semi-Fowler position). If the patient is unconscious, turn her on her side with the head of the bed slightly elevated.
- Assess for signs and symptoms of respiratory difficulty (i.e., dyspnea, wheezing, apprehension, and decreased breath sounds). Notify the healthcare provider at once.
- Check for hemoptysis (coughing up of excessive bloody secretions) and, if found, notify the healthcare provider. Inform the patient that some blood-tinged mucus may be coughed up and that this is not abnormal. It usually occurs following a biopsy or after a traumatic insertion of the bronchoscope.
- Assess the gag (cough) reflex before giving food and liquids. Ask the patient to swallow or cough. It normally takes 2–8 hours before the gag reflex returns. Offer ice chips and sips of water before offering food.
- Offer the patient lozenges or prescribed medication for mild throat irritation after the gag reflex is present.
- Be supportive of the patient. Touch the patient's hand or arm for reassurance, as necessary.

Patient Teaching

- Instruct the patient not to smoke for 6–8 hours. Smoking may cause the patient to cough and start bleeding, especially after a biopsy.
- Inform the patient that collection of postbronchoscopic secretions may be required for cytologic testing.

- Oral hygiene should be performed the night before the test and in the morning. This will decrease the number of bacteria that could be introduced into the lungs.
- Postural drainage is performed for 3 days before the test. This procedure aids in the removal of bronchial mucus and secretions. An expectorant (i.e., potassium iodide) may be ordered for 1–3 days before the test to loosen secretions and could detect an allergy to iodine.
- A sedative and atropine are usually given 1 hour before the test. The sedative/tranquilizer promotes relaxation; atropine reduces secretions during the test.
- A topical anesthetic is sprayed into the pharynx and trachea. A catheter is passed through the nose into the trachea, and a local anesthetic and iodized contrast liquid are injected through the catheter.
- The patient is usually asked to change body positions so that the contrast dye can reach most areas of the bronchial tree.
- Following the bronchography procedure, the patient may receive nebulization and should perform postural drainage to remove contrast dye. Food and fluids are restricted until the gag (cough) reflex is present.

Factors Affecting Diagnostic Results

- Secretions in the tracheobronchial tree can prevent the contrast dye from coating the bronchial walls.

Bronchoscopy

Normal Findings

Normal structure and lining of the larynx, trachea, and bronchi.

Description

Bronchoscopy is the direct inspection of the larynx, trachea, and bronchi through a standard metal bronchoscope or a flexible fiberoptic bronchoscope called a bronchofibroscope. The flexible fiberoptic bronchoscope has a lens and light at its distal end, and because of its small width and flexibility, it allows for visualization of the segmental and subsegmental bronchi.

Through the bronchoscope, a catheter brush, biopsy forceps, or biopsy needle can be passed to obtain secretions and tissues for cytologic examination.

Purpose

- To inspect the tracheobronchial tree.
- To remove foreign bodies and secretions from the tracheobronchial tree.
- To improve tracheobronchial drainage.

Procedure

- A consent form for bronchoscopy should be signed by the patient or an appropriate family member.
- The patient should be NPO for 6 hours before the bronchoscopy and preferably for 8–12 hours.
- The patient should remove dentures, contact lenses, jewelry.
- Obtain a history of hypersensitivity to analgesics, anesthetics, and antibiotics.
- Check vital signs and record.
- Administer premedications.
- Record vital signs, premedications, and when the patient voided on the preoperative check list and the patient's chart.
- The patient will be lying on a table in the supine or semi-Fowler position with the head hyperextended, or he will be seated in a chair. Local anesthetic will be sprayed in the patient's throat and nose, and the bronchoscope will be inserted through the patient's nose or mouth by the healthcare provider. It is frequently inserted through the mouth when using the rigid scope and is inserted through the nose when using the fiberoptic scope.
- Specimen containers should be labeled, and specimens should be taken immediately to the laboratory. The procedure takes about 1 hour.

Factors Affecting Diagnostic Results

- Improper labeling of the specimen.
- Failure to take specimens immediately to the laboratory.

Calcitonin (HCT) (Serum)

Reference Values

Adult: *Male*: Less than 40 pg/mL, less than 40 ng/L (SI units). *Female*: Less than 25 pg/mL, less than 25 ng/L (SI units).

Child: *Newborn*: Usually higher than in adults. *Child*: Less than 70 pg/mL, less than 70 ng/L (SI units).

Description

Calcitonin, a potent hormone secreted by the C cells of the thyroid gland, aids in maintaining normal serum calcium and phosphorus levels. This hormone is secreted in response to an elevated serum calcium level. It inhibits calcium reabsorption by the osteoclasts and osteocytes of the bones and increases calcium excretion by the kidneys. Calcitonin acts as an antagonist to the parathyroid hormone (PTH) and vitamin D, lowering serum calcium levels to maintain calcium balance in the body.

Excess calcitonin secretion occurs in medullary carcinoma of the thyroid (greater than 500–2,000 pg/mL [probable] and greater than 2,000 pg/mL [definite]).

When the serum calcitonin level is slightly to moderately elevated (100–500 pg/mL), a *calcitonin stimulation test* might be performed in diagnosis of thyroid medullary carcinoma. This test consists of either a 4-hour calcium infusion or a 10-second pentagastrin infusion with measurement of serum calcitonin before and after the infusion.

Purpose

- To aid in the diagnosis of thyroid medullary carcinoma or parathyroid hyperplasia or adenoma.
- To predict recurrence of medullary carcinoma after removal.

Calcium (Ca) and Ionized Calcium (Serum)

Reference Values

Adult: *Total Ca*: 4.5–5.5 mEq/L, 9–11 mg/dL, 2.3–2.8 mmol/L (SI units). *Ionized Ca*: 4.25–5.25 mg/dL, 2.2–2.5 mEq/L, 1.1–1.24 mmol/L.

Child: *Newborn*: 3.7–7.0 mEq/L, 7.4–14.0 mg/dL. *Infant*: 5.0–6.0 mEq/L, 10–12 mg/dL. *Child*: 4.5–5.8 mEq/L, 9–11.5 mg/dL.

Description

Calcium is found most abundantly in the bones and teeth. Approximately 50% of the calcium is ionized, and only ionized calcium can be used by the body. Protein and albumin in the blood bind with calcium, thus decreasing the amount of free, ionized calcium. The ionized calcium level can be determined by using formulas that estimate the ionized calcium from total calcium. These formulas have been disputed. Only a few laboratories have the equipment to perform serum-ionized calcium levels. In acidosis, more calcium is ionized, regardless of the serum level, and in alkalosis, most of the calcium is protein bound and cannot be ionized.

The *serum-ionized calcium* (iCa) level is not affected by changes in serum protein/albumin concentration, and it reflects calcium metabolism better than total calcium values. A decrease in ionized calcium, less than 2.2 mEq/L or less than 4.25 mg/dL, might lead to neuromuscular irritability or tetany symptoms (tingling, twitching, spasmodic contractions).

Calcium is necessary for the transmission of nerve impulses and contraction of the myocardium and skeletal muscles. It causes blood clotting by converting prothrombin into thrombin. It strengthens capillary membranes. With a calcium deficit, there is an increased capillary permeability, which causes fluid to pass through the capillary.

A low serum-calcium level is called *hypocalcemia*, and an increased level is called *hypercalcemia*. Calcium imbalances require immediate attention, because a serum calcium deficit can cause tetany symptoms, unless acidosis is present, and a serum calcium excess can cause cardiac dysrhythmias.

Purpose

- To check for serum calcium excess or deficit.

Calcium Channel Blockers (Serum)

Verapamil (Calan, Isoptin), Nifedipine (Procardia), Diltiazem (Cardizem)

Reference Values

Adult:

Drug Name	Therapeutic Range	Toxic Level
Verapamil	100–300 ng/mL 0.08–0.3 mcg/mL	300 ng/mL 0.3 mcg/mL
Nifedipine	50–100 ng/mL	100 ng/mL
Diltiazem	50–200 ng/mL	200 ng/mL

Note: Dosage is calculated according to mg/kg.

Purpose

- To monitor specific calcium channel blocker level to maintain therapeutic range.
- To detect toxic level for a specific calcium channel blocker.

Carbon Monoxide, Carboxyhemoglobin (Blood)

Reference Values

Adult: *Nonsmoker*: Less than 2.5% of hemoglobin. *Smoker*: 4–5% saturation of hemoglobin. *Heavy Smoker*: 5–12% saturation of hemoglobin. *Toxic*: Greater than 15% saturation of hemoglobin.

Child: Similar to adult nonsmoker.

Description

Carbon monoxide (CO) combines with hemoglobin to produce carboxyhemoglobin, which can occur 200 times more readily than the combination of oxygen with hemoglobin (oxyhemoglobin). When CO replaces oxygen in the hemoglobin in excess of 25%, CO toxicity occurs.

Carbon monoxide is formed from incomplete combustion of carbon-combining compounds, as in automobile exhaust, fumes from improperly functioning furnaces, and cigarette smoke. Continuous exposure to CO, increasing carboxyhemoglobin by greater than 60%, leads to coma and death. The treatment for CO toxicity is to administer a high concentration of oxygen.

Purpose

- To determine the percentage of CO in the hemoglobin.

Cardiac Catheterization

Cardiac Angiography (Angiocardiography), Coronary Arteriography

Normal Findings

Patency of coronary arteries; normal heart size, structure, valves; normal heart and pulmonary pressures; normal left ventricular function; normal wall motion.

Description

Cardiac catheterization is a procedure in which a long catheter is inserted into a vein and artery of the arm, groin, or neck. This catheter is threaded to the heart chambers and/or coronary arteries with the guidance of fluoroscopy. Contrast dye is injected for visualizing the heart structures. During injection of the dye, cineangiography is used for filming heart activity. The terms *angiocardiography* and *coronary arteriography* are used interchangeably with the term *cardiac catheterization*; however, with coronary arteriography, dye is injected directly into the coronary arteries, and with angiocardiology, dye is injected into heart, coronary, and/or pulmonary vessels.

With *right-cardiac catheterization*, the catheter is inserted into the femoral vein or an antecubital vein and threaded through the inferior vena cava into the right atrium to the pulmonary artery. Right atrium, right ventricle, and pulmonary artery pressures are measured, and blood samples from the right side of the heart can be obtained. While the dye is being injected, the functions of the tricuspid and pulmonary valves can be observed.

For *left-cardiac catheterization*, the catheter is inserted into the brachial or femoral artery and is advanced retrograde through the aorta to the coronary arteries and/or left ventricle. Dye is injected. The patency of the coronary arteries and/or functions of the aortic and mitral valves and the left ventricle can be observed. This procedure is indicated before heart surgery.

The frequency of complications arising from cardiac catheterizations is less than 2%. The complications that can occur, although rare, are myocardial infarction, cardiac dysrhythmias, cardiac tamponade, pulmonary embolism, and cerebrovascular accident (CVA). Other rare complications include renal failure or anaphylactic reaction to contrast dye, blood clot at catheter site requiring anticoagulation, or significant internal bleeding near insertion site.

Purposes

- To identify coronary artery disease (CAD).
- To determine cardiac valvular disease.
- To determine pressure in pulmonary vessels or heart chambers.
- To obtain a biopsy of myocardium.
- To evaluate artificial valves.
- To replace aortic valve via percutaneous approach.
- To perform percutaneous valvuloplasty.
- To determine left ventricular injection fraction.
- To repair APFO, ASD percutaneously.
- To angioplasty or stent an area resulting from coronary artery disease (CAD).

Nursing Implications with Rationale

Cardiac Catheterization

Pretest

- Explain to the patient that the purpose of the test is to check the coronary arteries for blockage, to check for heart valve defects, and/or to measure pressures in the pulmonary vessels, heart chambers, or obtain a biopsy of heart tissue. This test is often done before heart surgery to determine if bypass or valvular surgery is necessary.
- Explain the procedure to the patient. The cardiologist or cardiac surgeon should explain the risk factors to the patient.
- Obtain a patient history of allergic reactions to seafood, iodine, or iodine contrast dye used in other x-ray tests (e.g., intravenous pyelography). A skin test may be performed to determine the severity of the allergy. An antihistamine (e.g., diphenhydramine [Benadryl]) and steroids may be given the day before and/or the day of the test as a prophylactic measure.
- Record baseline vital signs (VS), and monitor the VS during the procedure.
- Check that the catheter insertion site has been prepped (clipped and cleansed with an antiseptic). This will prevent infection.
- Assess the patient with renal insufficiency. Premedication with acetylcysteine and/or sodium bicarbonate IV may be administered for renal protection from contrast dye 24 hours before and after the procedure. Alternatively, the patient may receive IV hydration with a large volume of normal saline solution.
- If the patient is on metformin, hold the medication for 2 days before and 2 days after the procedure. Metformin and IV contrast may result in lactic acidosis.
- Encourage the patient to ask questions, and allow the patient and family time to express any concerns. Refer questions you cannot answer to the cardiologist or other health professionals.
- Administer premedications 1/2 to 1 hour before the test. Make sure that the patient has voided and that the consent form has been signed before giving the premedications.

Patient Teaching

- Inform the patient that he or she will be in a special cardiac catheterization room. Give information about the padded table, the ECG leads to monitor heart activity, the IV fluids, the local skin anesthetic, and instructions that he may receive (such as to cough and to breathe deeply).
- Inform the patient that there may be minimal discomfort at the catheter insertion site and from lying on the back. Instruct the patient to ask any questions he may have during the test. Tell the patient to tell the healthcare provider of any chest pain or difficulty in breathing during the procedure. The patient's ECG and VS are monitored.
- Tell the patient that a hot, flushing sensation may be felt for a minute or two because of the dye. The reason for this is a brief vasodilation caused by the dye.
- Tell the patient that the test takes approximately 1/2 to 3 hours.

Posttest

- Monitor VS (blood pressure, pulse, respirations) every 15 minutes the first hour, every 30 minutes until stable, or as ordered. Temperatures are monitored for several days.
- Watch for cardiac rhythm and rate disturbances. Notify cardiologist of any changes from baseline.
- Assess patient for complaints of chest heaviness, shortness of breath, and abdominal or groin pains.
- Observe the catheter insertion site for bleeding or hematoma. Change dressings as needed. If bleeding or hematoma develops at the site, hold pressure for 20 minutes and contact the cardiologist.
- Check peripheral pulses below the insertion site; if the femoral artery was used, then check the popliteal and dorsalis pedis pulses; if the brachial artery was used, then check the radial pulse. If the radial artery was used, check the ulnar pulse. Note the strength of the pulse beat. Perform neurovascular assessment of access limb with each vital sign check.
- Assess the patient's skin color and temperature.
- Be supportive of the patient and family. Answer questions, or refer them to the appropriate health professionals. Communicate with the patient about the nursing care being given.
- Encourage patient to increase fluid intake to flush the dye from the system.
- Administer narcotic analgesics or analgesics as ordered for discomfort. Give antibiotics, if ordered.

Patient Teaching

- Instruct the patient that he is to remain on bedrest for 2–4 hours. The patient can turn from side to side, and the bed may be elevated 30 degrees. The leg should be extended if the femoral artery was used. If the brachial artery was used, the head of the bed can be slightly elevated; however, the arm should be immobilized for 3 hours. Policy concerning positioning may differ among institutions.
- Instruct the patient to lie down and apply pressure to the site if experiencing a small amount of bleeding. The patient should call 911 if experiencing a moderate to large amount of bleeding.
- Explain to the patient that a small lump may form at the site of the incision. If the lump increases to the size of a golf ball or larger, the patient should contact the cardiologist or go to the emergency department.
- Instruct the patient not to do any heavy lifting or driving for 24–48 hours.
- Encourage fluid intake after the test, unless contraindicated (e.g., in the case of heart failure).

Procedure

- Obtain a signed consent form. Check that the healthcare provider has discussed possible risk factors before the consent form is signed.
- Food and fluids are restricted for 6–8 hours before the test, according to the hospital's policy. Some institutions permit clear liquids until 4 hours before the test.
- Antihistamines (e.g., diphenhydramine [Benadryl]) and steroids may be ordered the evening before and the morning of the test if the patient has a history of allergic reactions to substance.
- Medications should be given as ordered by the healthcare provider. Oral anticoagulants are discontinued to prevent excessive bleeding. Heparin may be ordered to prevent thrombi.
- The injection site of the arm or groin is shaved and cleansed with antiseptics.
- The modified Allen test must be performed before using the radial artery to ensure collateral circulation to the hand during annulation of the artery.
- The weight and height of the patient should be recorded. These are used to calculate the amount of dye needed (i.e., 1 mL/kg of body weight).
- The patient should void before receiving the premedications. Dentures should be removed.
- Record baseline VS. Note the volume intensity of pulses. VS should be monitored during the test.
- Premedications may be given 1/2 to 1 hour before the cardiac catheterization.
- The patient is positioned on a padded table. Skin anesthetic is given at the site of catheter insertion. Patient lies still during insertion of the catheter and filming.
- A 5% dextrose in water (D₅W) infusion is started at a keep-vein-open (KVO) rate for administering emergency drugs, if needed. Occasionally, a higher rate of IV infusion of normal saline solution (NSS) or 1/2 NSS is administered prior to and during catheterization to prevent renal failure from contrast dye.
- Electrocardiography (ECG) leads are applied to the chest skin surface to monitor heart activity.
- A local skin anesthetic is injected at the catheter insertion site. A cutdown to locate the vessel may be needed. The patient will feel a hot, flushing sensation for several seconds to a minute as the dye is injected.
- Coughing and deep breathing are frequently requested by the healthcare provider. Coughing can decrease nausea and dizziness and possible dysrhythmia.
- The procedure takes 1–3 hours.

Factors Affecting Diagnostic Results

- Insufficient amount of contrast dye could affect results.
- Movement by the patient could cause complications and interfere with the filming.

Catecholamines (Plasma)

Reference Values

Epinephrine: *Supine*: Less than 50 pg/mL. *Sitting*: Less than 60 pg/mL. *Standing*: Less than 90 pg/mL.

Norepinephrine: *Supine*: 110–410 pg/mL. *Sitting*: 120–680 pg/mL. *Standing*: 125–700 pg/mL.

Dopamine: *Supine and Standing*: Less than 87 pg/mL.

Pheochromocytoma: *Total Catecholamines*: Greater than 1000 pg/mL.

Cerebrospinal Fluid (CSF)

(Color, Pressure, Cell Count, Protein, Chloride, Glucose, Culture) Spinal Fluid

Reference Values

	Color	Pressure (mm H ₂ O)	Cell Count (Leukocytes) (mm ³ , μ L)
Adult	Clear, colorless	75–175	0–8
Child	Clear, colorless	50–100	0–8
Premature infant			0–20
Newborn	Clear		0–15
1–6 months			

	Protein (mg/dL)	Chloride (mEq/L)	Glucose (mg/dL)
Adult	15–45	118–132	40–80
Child	14–45	120–128	35–75
Premature infant	<400		
Newborn	30–200	110–122	20–40
1–6 months	30–100		

Description

Cerebrospinal fluid (CSF), also known as spinal fluid, circulates in the ventricles of the brain and through the spinal cord. Of the 150 mL of CSF, approximately 100 mL are produced by the blood in the brain ventricles and reabsorbed back into circulation daily.

Spinal fluid is obtained by a lumbar puncture (spinal tap) performed in the lumbar sac at L3–L4, or at L4–L5. First, CSF pressure is measured, then fluid is aspirated and placed in sterile test tubes.

Purpose

- To aid diagnosis of spinal cord and brain diseases.

CSF Analysis for Clinical Problems

CSF	Decreased Level	Elevated Level	Comments
Color		Abnormal color: 1. Pink or red—subarachnoid or cerebral hemorrhage; traumatic spinal tap 2. Xanthochromia (yellow color)—previous subarachnoid hemorrhage	Yellow color indicates old blood (4–5 days after a cerebral hemorrhage), mixture of bilirubin and blood, or extremely elevated protein levels; fluid discoloration normally remains for 3 weeks.
Pressure	Dehydration, hypovolemia	Intracranial pressure due to meningitis, subarachnoid hemorrhage, brain tumor, brain abscess, encephalitis	Slight elevation can occur with holding breath or tensing of muscles.
Cell count (lymphocytes)		<500 mm ³ (μL): viral infections poliomyelitis, aseptic meningitis, syphilis of CNS; multiple sclerosis; brain tumor; abscess; subarachnoid hemorrhage (40% or more monocytes) >500 mm ³ (μL): ↑ granulocytes, purulent infection	WBC differential count may be ordered to identify the types of leukocytes.
Protein		Meningitis: tuberculosis, purulent, aseptic Guillain-Barré syndrome Subarachnoid hemorrhage Brain tumor Abscess syphilis Drug influence: anesthetics acetophenetidin (phenacetin) chlorpromazine (Thorazine) salicylates (aspirin) streptomycin sulfonamides	Protein and cell counts usually increase together.
Chloride	Tubercular meningitis Bacterial meningitis		IV saline or electrolyte infusion could cause an inaccurate result. Syphilis, brain tumors and abscess, and encephalitis do not affect the CSF chloride level.
Glucose	Purulent meningitis Presence of fungi, protozoa, or pyogenic bacteria Subarachnoid hemorrhage Lymphomas Leukemia	Cerebral trauma Hypothalamic lesions Diabetes (hyperglycemia)	Brain abscess or tumor and degenerative diseases have little effect on the CSF glucose. The CSF glucose is usually two thirds of the blood glucose. The blood glucose level is determined for comparative reasons.
Culture		Meningitis	Generally done when meningitis is suspected.

Chlamydia (Serum and Tissue Smear or Culture)

Reference Values

Normal Titer: Less than 1:16.

Positive Titer: Equal to or greater than 1:64.

Description

Chlamydia is a bacteria-like organism that has some features of a virus. The two species of chlamydia are *C. psittaci*, which can cause psittacosis in birds and humans, and *C. trachomatis*, which appears in three types: lymphogranuloma venereum (LGV, venereal disease), genital and other infections, and trachoma (eye disorder).

The occurrence of *C. psittaci* is more common in individuals working in pet stores who may have contact with infected birds such as parakeets, and in those working in the poultry industry who may come in contact with infected turkeys. A respiratory infection may result and could cause chlamydia

pneumonia. Serologic testing or tissue culture may be performed for diagnosis.

The *C. trachomatis* strain, LGV, is transmitted through sexual intercourse. It can occur in both males and females, causing enlargement of the inguinal and pelvic lymph nodes. Pregnant women can pass chlamydia infection to the newborn during birth. This can cause trachoma ophthalmia neonatorum in the infant, which may lead to blindness later if untreated. Untreated genital infections caused by *C. trachomatis* could lead to sterility.

With psittacosis and LGV, the serum titer level is greater than 1:64 (more than 4 times the reference value). The titer level for genital infection caused by *C. trachomatis* is usually between 1:16 and 1:64. Tissue culture may be used to confirm test results with the titer level. Tetracycline and erythromycin, not penicillin, are usually the antibiotics used to treat chlamydia.

Purpose

- To identify the presence of a chlamydial infection (*C. psittaci* or *C. trachomatis*).

Chloride (Cl) (Serum)

Reference Values

Adult: 95–105 mEq/L, 95–105 mmol/L (SI units).

Child: *Newborn*: 94–112 mEq/L. *Infant*: 95–110 mEq/L.

Child: 98–105 mEq/L.

Description

Chloride is an anion found mostly in the extracellular fluid. Chloride plays an important role in maintaining body water balance, osmolality of body fluids (with sodium), and acid–base balance. It combines with hydrogen ion to produce the acidity (hydrochloric acid [HCl]) in the stomach.

For maintaining acid–base balance, chloride competes with bicarbonate for sodium. When the body fluids are more acidic, the kidneys excrete chloride and sodium, and bicarbonate is reabsorbed. In addition, chloride shifts in and out of red blood cells in exchange with bicarbonate.

Most of the chloride ingested is combined with sodium (sodium chloride [NaCl] or “salt”). The daily required chloride intake is 2 g. *Hypochloremia* means serum chloride deficit; *hyperchloremia* means serum chloride excess.

Purpose

- To check the chloride level in relation to potassium, sodium, and acid–base balance.

Chloride (Sweat)

Screening (Silver Nitrate); Iontophoresis (Pilocarpine)

Reference Values

Adult: Less than 60 mEq/L.

Child: Less than 50 mEq/L. *Marginal*: 50–60 mEq/L.

Abnormal: Greater than 60 mEq/L (possible cystic fibrosis).

Description

Sodium and chloride concentrations in sweat are higher in people with cystic fibrosis, even though there usually is not an increased amount of sweat. Sweat chloride is considered more reliable than sweat sodium for diagnostic purposes. Some falsely negative sweat sodium levels have been reported in people with cystic fibrosis.

Two types of sweat chloride tests are used: (1) screening tests, which use silver nitrate on agar or filter (special) paper and require contact with the hand (palm or fingers), and (2) iontophoresis, in which pilocarpine is placed on the forearm to increase sweat gland secretion. A positive screening test is usually validated with iontophoresis, because the chloride level in the palm of the hand is usually higher than anywhere else. Some healthcare providers believe that the screening should be routine in all children; however, others disagree.

Purpose

- To aid in the detection of cystic fibrosis.

Procedure

Screening Test (Silver Nitrate)

- Wash the child’s hand and dry it. For 15 minutes, keep the hand from contacting any other part of the body.

- Moisten the test paper containing silver nitrate compound with distilled water (*not saline*).
- Press the child’s hand on the paper for 4 seconds.
- A positive result occurs when the excess chloride combines with the silver nitrate to form white silver chloride on the paper.
- A heavy hand imprint is left by the child with cystic fibrosis.

Iontophoresis (Pilocarpine): Usually performed by laboratory personnel.

- Food and fluids are not restricted.
- Electrodes are placed on the skin of the forearm to create a small electric current for transporting pilocarpine (a stimulating drug) into the skin to induce sweating.
- Sweat is collected and weighed. Chloride is measured.

Factors Affecting Laboratory Results

- Unwashed hands for the screening test affect test results.
- Use of saline solution to moisten the test paper causes inaccurate test results.

Cholangiography (Intravenous, Percutaneous, T-tube Cholangiography)

Normal Findings

Patent biliary ducts (absence of stones and strictures).

Description

Intravenous (IV) cholangiography examines the biliary ducts (hepatic ducts within the liver, the common hepatic duct, the cystic duct, and the common bile duct) by radiographic and tomographic visualization. Often the gallbladder is not well visualized. The contrast substance, an iodine preparation such as iodipamide meglumine (Cholografin), is injected intravenously. Approximately 15 minutes later x-rays are taken. IV cholangiography is a tedious and time-consuming test, and reactions are more common with the IV contrast substance than with the oral agents.

Nursing Implications with Rationale Chloride (Sweat)

- Explain the procedures (screening or iontophoresis or both) to the child and family. Answer questions if possible, or refer them to appropriate health professionals.
- Explain to the child and family that the tests are not painful.
- Remain with the child during the procedure. Give comfort and reassurance as needed.

Increased Level

- Associate an elevated sweat chloride level with cystic fibrosis. With cystic fibrosis, sweat chloride levels could be 2 to 5 times greater than normal.
- Obtain a familial history of cystic fibrosis, when indicated.
- Determine whether the child has washed and dried his or her hands before the screening test is performed. Dried sweat can leave a chloride residue, thus causing a false-positive result.

Percutaneous cholangiography is indicated when biliary obstruction is suspected. The contrast substance is directly instilled into the biliary tree. The process is visualized by fluoroscopy, and spot films are taken.

T-tube cholangiography, also known as postoperative cholangiography, may be done 7–8 hours after a cholecystectomy to explore the common bile duct for patency of the duct and to see if any gallstones are left. During the operation, a T-shaped tube is placed in the common bile duct to promote drainage. The contrast substance is injected into the T-tube. A stone or two could be missed during a cholecystectomy, causing occlusion of the duct.

Cholesterol (Serum)

Reference Values

Adult: Desirable Level: Less than 200 mg/dL. *Moderate Risk:* 200–240 mg/dL. *High Risk:* Greater than 240 mg/dL.

Pregnancy: High risk levels but a return to prepregnancy values 1 month after delivery.

Child: Infant: 90–130 mg/dL. *Child (2–19 Years): Desirable Level:* 130–170 mg/dL. *Moderate Risk:* 171–184 mg/dL. *High Risk:* Greater than 185 mg/dL.

Description

Cholesterol is a blood lipid synthesized by the liver and is found in red blood cells, cell membranes, and muscles. About 70% of cholesterol is esterified (combined with fatty acids), and 30% is in the free form. Cholesterol is used by the body to form bile salts for fat digestion and for the formation of hormones by the adrenal glands, ovaries, and testes. Thyroid hormones and estrogen decrease the concentration of cholesterol, and an oophorectomy increases it.

Serum cholesterol is used as an indicator of atherosclerosis and coronary artery disease. Hypercholesterolemia causes plaque deposits in the coronary arteries, thus contributing to myocardial infarction. High serum cholesterol levels can be due to a familial (hereditary) tendency, biliary obstruction, and/or dietary intake. Approximately one third of Americans have a serum cholesterol level below 200 mg/dL, which is desirable.

Purpose

- To monitor cholesterol levels.

Clinical Problems

Decreased Level: Hyperthyroidism, Cushing syndrome (adrenal hormone excess), starvation, malabsorption, anemias, acute infections. **Drug Influence:** Antilipids (Zocor, Mevacor, Lipitor), thyroxine, antibiotics (kanamycin, neomycin, paromomycin, tetracycline), nicotinic acid, estrogens, glucagon, heparin, salicylates (aspirin), colchicine, oral hypoglycemic agents.

Increased Level: Acute myocardial infarction; atherosclerosis, hypothyroidism, biliary obstruction; biliary cirrhosis; cholangitis; familial hypercholesterolemia; uncontrolled diabetes mellitus; nephrotic syndrome; pancreatectomy; pregnancy (third trimester); types II, III, and V hyperlipoproteinemia; heavy stress periods; high-cholesterol diet (animal fats). **Drug Influence:** Aspirin,

Nursing Implications with Rationale Cholesterol

Increased Level

- Relate clinical problems and drugs to hypercholesterolemia. An elevated cholesterol level can indicate liver disease as well as coronary artery disease.
- Hold drugs that could increase the serum level for 12 hours before the blood is drawn, with the healthcare provider's permission.

Patient Teaching

- Explain to the patient and family what is considered a normal serum cholesterol level and the effects of an elevated cholesterol level.
- Encourage the patient to lose weight if overweight and hypercholesterolemic. Losing weight if obese can decrease serum cholesterol level.
- Instruct the patient with hypercholesterolemia to decrease the intake of foods rich in cholesterol (i.e., bacon, eggs, butter, fatty meat, certain seafood, coconut, and chocolate).
- Teach the patient with severe hypercholesterolemia to keep medical appointments for follow-up care.

corticosteroids, steroids (anabolic agents and androgens), oral contraceptives, epinephrine and norepinephrine, bromides, phenothiazines (chlorpromazine [Thorazine], trifluoperazine [Stelazine]), vitamins A and D, sulfonamides, phenytoin (Dilantin).

Procedure

- Keep the patient NPO (food, fluids, and medications) for 12 hours. The patient may have water.
- Collect 3–5 mL of venous blood in a red-top tube. Avoid hemolysis.
- List drugs the patient is taking that are not withheld on the laboratory slip.

Factors Affecting Laboratory Results

- Aspirin and cortisone could cause decreased or elevated serum cholesterol levels.
- A high-cholesterol diet before the test could cause elevated serum cholesterol levels.
- Severe hypoxia could increase the serum cholesterol level.
- Hemolysis of the blood specimen may cause an elevation of the serum cholesterol level.

Chorionic Villi Biopsy (CVB)

Normal Findings

Normal fetal cells.

Description

Chorionic villus sampling can detect early fetal abnormalities. Fetal cells are obtained by suction from fingerlike projections around the embryonic membrane, which eventually

Nursing Implications with Rationale

Chorionic Villi Biopsy

- Obtain a history of last menstrual period (LMP) from the patient and a history of family genetic disorders.
- Assess for signs of spontaneous abortion resulting from procedure, such as cramping, bleeding.
- Assess for infection resulting from procedure, such as chills, fever.
- Be supportive of patient and family. Be a good listener.

Patient Teaching

- Explain to the patient that she will be in a lithotomy position and that ultrasound is used during the procedure.
- Instruct the patient to report if excessive bleeding or severe cramping occurs after the procedure.

becomes the placenta. The test is performed between the 8th and 10th weeks of pregnancy. After the 10th week, maternal cells begin to grow over the villi.

Purpose

- To detect chromosomal disorders.

The advantages of CVB over amniocentesis are that CVB may be performed earlier, and results can be obtained in a few days and not weeks. CVB can diagnose many chromosomal and biochemical fetal disorders. The disadvantage is that CVB cannot determine neural-tube defects and pulmonary maturity.

Procedure

- A consent form should be signed.
- Food and fluids are not restricted.
- Place the patient in the lithotomy position.
- Ultrasound is used to verify the placement of the catheter at the villi. Suction is applied, and tissue is removed from the villi.
- Test takes approximately 30 minutes.

Factors Affecting Diagnostic Results

- Performing test after 10 weeks of gestation.

Colonoscopy

Normal Findings

Normal mucosa of the large intestine; absence of pathology.

Description

Colonoscopy, an endoscopic procedure, is an inspection of the large intestine (colon) using a long, flexible fiberoptic (colonoscope). The instrument is inserted anally and is advanced through the rectum, the sigmoid colon, and the large intestine to the cecum.

Biopsy of the tissue or polyp can be obtained. The biopsy forceps passes through the scope to obtain the tissue

specimen. Polyps can be removed with the use of an electrocautery snare.

Colonoscopy should not be done on pregnant women near term, after recent abdominal surgery, or in a confused/uncooperative patient. Caution should be taken in performing a colonoscopy following an acute myocardial infarction, in acute diverticulitis, or in severe (active) ulcerative colitis. Rarely, colon perforation is caused by the fiberoptic. Bleeding may occur after a biopsy or polypectomy.

Screening for polyps for the patient over the age of 50 is important. However, if the patient has a familial history of colon cancer, a colonoscopy may be recommended before the age of 50. Colon cancer is usually caused by adenomatous polyps, and if the polyps are removed early, cancer of the colon would be unlikely.

Virtual Colonoscopy

A virtual colonoscopy is an examination of the colon by computed tomography (CT) scanning of the entire large colon. It is currently not as accurate as the traditional colonoscopy, because small polyps are difficult to detect with this procedure. In a major study, virtual colonoscopy missed 45% of polyps that were 5 mm or smaller. Differentiation of stool from polyps can be difficult.

The patient still has to undergo the same colon prep before a virtual colonoscopy as a person would with a traditional colonoscopy. Traditional colonoscopy is required to remove a polyp found on a CT scan of the colon. Virtual colonoscopy has advantages over traditional colonoscopy in that no sedatives are required, the procedure is less invasive,

Nursing Implications with Rationale

Colonoscopy

Pretest

- The patient should follow the pretest preparation procedure.
- Explain the procedure to the patient. The patient lies in the Sims position or left lateral position. A lubricated colonoscope is inserted. Air will be insufflated for better visualization. Photos are usually taken of any abnormal tissue or polyps.
- Record baseline vital signs and, if available, pertinent laboratory values.
- Report anxiety and fears to the physician or health professional prior to the test.

Patient Teaching

- Instruct the patient to bring someone to provide a ride home.
- Instruct the patient to breathe deeply and slowly through the mouth during the insertion of the colonoscope.
- Inform the patient that the procedure takes approximately 15 minutes to 1 hour.

Posttest

- Monitor vital signs and report abnormal changes.
- Assess for anal bleeding, abdominal distention, severe pain, severe abdominal cramps, and fever, and report any of the signs or symptoms immediately.

B-24 Appendix B Diagnostic Values and Laboratory Tests

and additional information outside the colon may also be found—for example, incidental renal cell cancer.

Purpose

- To detect the origin of lower intestinal bleeding.
- To evaluate suspicious lesions such as polyps in the large intestine.
- To screen for benign or malignant lesions (tumors) in the intestine.

Procedure

- A consent form should be signed.
- Specific laboratory tests may be ordered, such as CBC, INR (if patient has taken Coumadin).
- Withhold medications that interfere with coagulation, such as aspirin, NSAIDs (Advil, Motrin), iron medication, and alcohol, 1 week prior to the test.
- Barium sulfate from other diagnostic studies can decrease visualization; therefore, the colonoscopy should not be attempted within 10 days to 2 weeks of a barium study.
- Avoid using soapsuds enemas. These can irritate the intestines.
- Emergency drugs and equipment should be available for hypersensitivity to medications (premedications and anesthetic).
- Specimen containers should be labeled with the patient's name, date, and the type of tissue.
- Patient should be accompanied by someone who can drive her home following the test.
- The procedure takes approximately 15 minutes to 1 hour.

Pretest Procedure

- Two days before the exam, the patient should avoid eating seeds, nuts, corn, and any other forms of roughage or fiber. The patient should not take Metamucil or Citrucel.
- The day before the procedure, the patient may have “clear liquids” only, which include water, tea, coffee (without milk), strained fruit juices without pulp (apple, white grape, lemonade), plain gelatin (without added fruits or toppings), clear broths or bouillon (chicken or beef without noodles or solids), noncarbonated sports drinks, and carbonated and noncarbonated soft drinks. All red fluids should be avoided because of the color of the dye, which can affect the visualization of the test.

Preparation (Use of Golytely/Colyte Solution or Magnesium Citrate Solution)

Day Before the Test:

- Patient should prepare GoLyte or Colyte solution according to instructions, and refrigerate solution.
- Patient should drink GoLyte/Colyte as instructed, usually 7 p.m. to 10 p.m.
- If magnesium citrate is ordered, purchase two 10-ounce bottles of magnesium citrate. Follow the instructions given by the healthcare provider or physician.

Medication Procedure

- Intravenous fluids with Diprivan (Propofol), midazolam (Versed), or meperidine (Demerol) for conscious sedation are given immediately prior to the test.

Factors Affecting Diagnostic Results

- A soapsuds enema can cause intestinal irritation.
- Barium sulfate from other diagnostic studies can decrease visualization; therefore, the study should not be attempted within 10 days to 2 weeks of a barium study.
- Inadequate bowel preparation with fecal material remaining in the colon will decrease visualization.

Colposcopy

Normal Findings

Normal appearance of the vagina and cervical structures.

Description

Colposcopy is the examination of the vagina and cervix using a binocular instrument (colposcope) that has a magnifying lens and a light. After a positive Papanicolaou (Pap) smear or a suspicious cervical lesion, colposcopy is indicated for examining the vagina and cervix more thoroughly. Atypical epithelium, leukoplakia vulvae, and irregular blood vessels can be identified with this procedure, and photographs and a biopsy specimen can be obtained.

This test may be performed in a gynecologist's office or in a hospital. As this test has become more popular, the need for conization (surgical removal of a cone of tissue from the cervical os) has decreased.

Purpose

- To identify precancerous lesions of the cervix
- To identify vaginal lesions.
- To monitor patients who have had cervical lesions removed.
- To monitor women whose mothers received diethylstilbestrol during pregnancy.

Procedure

- A consent form should be signed.
- Food and fluids are not restricted.
- The patient's clothes should be removed, and the patient should wear a gown and be properly draped.
- The patient assumes a lithotomy position (legs in stirrups). A speculum is inserted into the vagina, and a long, dry cotton-swab applicator is used to clear away any cervical secretions. Another long cotton-swab applicator with saline may be used to swab the cervix for visualizing vascular patterns.
- Acetic acid (3%) is applied to the vagina and cervix. This produces color changes in the cervical epithelium, which helps in detecting abnormal changes.
- A biopsy specimen of suspicious tissues and photographs may be taken. Pressure should be applied to control bleeding at the biopsy site, or cautery may be used.

- A vaginal tampon may be worn after the procedure.
- The test takes approximately 15–20 minutes.

Factors Affecting Diagnostic Results

- Mucus, cervical secretions, creams, and medications can decrease visualization.

Computed Tomography (CT) Scan, Computed Axial Tomography (CAT)

CAT Scan, Computed Transaxial Tomography (CTT), EMI Scan

Normal Findings

Normal tissue; no pathologic findings.

Description

The CT scanner produces a narrow x-ray beam that examines body sections from 360 degrees. The CT scanner can rotate around the patient who is lying on a table. It produces a series of cross-sectional images in sequence that build up a two-dimensional (2D) picture of the organ or structure. The traditional x-ray takes a flat or frontal picture, which also gives a two-dimensional view. The CT scanner is about 100 times more sensitive than an x-ray machine in separating different soft tissue densities. Although it is a costly diagnostic test, CT scanning is popular because it can diagnose at an earlier stage.

The CT scan can be performed with or without iodine contrast media (dye). It is not an invasive test unless contrast dye is used. The contrast dye causes greater tissue absorption and is referred to as *contrast enhancement*. This enhancement enables small abnormalities to be seen.

CT is capable of scanning the head (internal auditory canal, brain, eye orbits, sinuses, and neck), abdomen (stomach, small and large intestines, liver, spleen, pancreas, bile duct, kidney, and adrenals), pelvis (bladder, reproductive organs, and small and large bowel within pelvis), chest (lung, heart, mediastinal structure), and bones and joints. Magnetic resonance imaging (MRI), a noninvasive test, has not replaced CT scans; see discussion of MRI.

Recent advances in the helical (spiral) CT scanning technique allow for imaging without blurring of moving organs such as the heart. In 30 seconds, a multislice CT (MSCT) can be performed with one breath hold.

Head and Brain CT

The CT of the brain/head provides 2D views of the brain consisting of cross-sectional images of brain tissue layers. This procedure can differentiate among tumors, aneurysms, cerebral infarction, and intracranial hemorrhage and hematoma. Also, this CT scan can detect ventricular displacement or enlargement. Visualization of the pathology can be enhanced with IV iodinated contrast dye.

Chest (Thoracic) CT

CT of the chest gives a cross-sectional view of the chest to differentiate among various pathologic conditions: tumors, nodules, cysts, abscesses, hematomas, and aortic aneurysms. It can detect pleural effusion and enlarged lymph nodes in

the chest area. The use of IV contrast media aids in highlighting blood vessels, thus identifying abnormalities of the vascular structures. CT of the chest can be useful in evaluating the effects of treatment therapy on the tumor and whether metastasis has occurred. The helical or spiral CT imaging can readily detect pulmonary emboli more than 90% of the time.

Abdominal CT

CT of the abdomen is useful for diagnosing tumors, obstructions, cysts, hematoma, abscesses, bleeding, perforation, calculi, fibroids, and other pathologic conditions that appear in the liver, biliary tract, pancreas, spleen, GI tract, gallbladder, kidneys, adrenals, uterus and ovaries, and prostate. IV contrast dye may be used to enhance visualization. The kidney and urinary flow is easily seen with the use of contrast dye. Oral contrast media may be used for scanning the GI tract. The CT scan is useful for staging tumors and monitoring the effects of treatment therapy on the tumor.

Spine CT

CT scan of the spine gives cross-sectional images that are displayed as 2D views on a monitor. It can be reconstructed in the sagittal and coronal plane, or as a 3D surface rendering. It is mainly used to view the bony landmarks. Contrast dye may be injected into the spinal column via lumbar puncture for clearer visualization of nerve roots and disc herniation. MRI is the preferred study of the spine; however, if MRI is contraindicated or unavailable, then contrast CT would likely be ordered.

Long Bones and Joints CT

Skeletal CT provides cross-sectional images of the bone. This procedure is useful to detect bone and soft tissue tumors and bone metastases. Joint abnormalities can be identified with this CT. Contrast dye may be ordered.

Purpose

- To screen for coronary artery disease; head, liver, and renal lesions; tumors; edema; abscesses; infection; metastatic disease; vascular diseases; stroke; and bone destruction.
- To locate foreign objects in soft tissues (such as the eye).

Procedure

General Preparation for All Scans

- A consent form should be signed.
- There is no food or fluid restriction if contrast dye is NOT used.
- For IV contrast injection studies, usually the patient is NPO (nothing by mouth) 4 hours prior to the CT. People with diabetes may be given orange juice instead of water; check with the healthcare provider or CT supervisor. Oral hypoglycemic agents (Glucophage) are contraindicated with iodinated contrast. For PM scheduling: NPO after a liquid breakfast.
- Prescribed medications may be given with a small amount of water prior to the CT scan; check with the healthcare provider or CT supervisor.

B-26 Appendix B Diagnostic Values and Laboratory Tests

- A mild sedative may be ordered for some patients to alleviate anxiety.
- Patient should remain motionless during the procedure.
- If contrast media (dye) is ordered and the patient is allergic to iodine products, steroids or antihistamines may be given before the scan or may be given IV during the CT scan.
- IV infusion or heparin lock insertion may be required prior to test. Use a 19- or 20-gauge needle. Never insert the needle into the antecubital area (anterior bend of the elbow).
- CT scanning usually takes 15 minutes.

Head CT

- Remove hairpins, braids, clips, and jewelry (earrings) before the test.
- Remove dentures prior to the use of contrast dye.
- A mild sedative or analgesic may be ordered for restless patients or for those who have aches and pains of the neck or back.
- Head is positioned in a cradle, and a wide, rubberized strap is applied snugly around the head to keep it immobilized during the test.

Neck CT

- IV contrast media is usually used. Check general preparation for scan for IV contrast injection studies.

Abdominal and Pelvic CT

- Abdominal x-ray (including the kidneys, ureters, and bladder) may be requested before CT scan.
- The gastrointestinal tract must be free from barium. An enema may be ordered.
- Current laboratory reports of serum creatinine and blood urea nitrogen should be available to determine if there is kidney dysfunction and, if so, to what degree. These tests should be done 7 days prior to the CT scan with contrast injection.
- For an a.m. abdominal/pelvic scan, give the oral contrast media (15 oz) between 8 p.m. and 10 p.m. the evening before the scan. NPO after 10 p.m. One hour prior to the CT, give a further 1/2 bottle of the oral contrast. One-half hour prior to the CT, give the remaining 1/2 bottle of oral contrast.
- For a p.m. abdominal/pelvic scan, give 1 bottle (15 oz) of oral contrast media at 7 a.m. the morning of the scan. NPO after 7 a.m. One hour prior to the CT, give 1/2 bottle of the oral contrast. One-half hour prior to the CT, give 1/2 bottle of the oral contrast.

Chest CT

- A chest x-ray may be requested before a chest scan.
- IV contrast medium is frequently given in the left arm.

Spine CT

- NPO is not indicated, because a contrast medium is usually not ordered.
- Spine x-rays taken prior to scan should be available. Spine CT should be done after myelography.

Nursing Implications with Rationale Computed Tomography Scan

Pretest

- Explain the procedure to the patient. The CT scanner is circular, with a doughnut-like opening. The patient is strapped to a special table, with the scanner revolving around the body area that is to be examined. Clicking noises will be heard from the scanner. The radiologist or specialized technician is stationed in a control room and can observe and communicate with the patient at all times through an intercom system. The test is not painful.
- Inform the patient that holding breath may be requested several times during an abdominal or thoracic scan.
- Inform the patient that the CT of the head takes 5 minutes without contrast media and 10 minutes with use of contrast. Body CT tests take 5–15 minutes.
- Obtain a history of allergies to seafood, iodine, and contrast dye from other x-ray tests. Contrast enhancement is not always done with CT.
- Advise the patient that if contrast dye is injected IV, a warm, flushed sensation may be felt in the face or body. A salty, “fishy,” or metallic taste, and a sensation of urinating (does not occur) may be experienced. Nausea is not uncommon. These sensations usually last for 1 or 2 minutes.
- Observe for signs and symptoms of a severe allergic reaction to the dye (i.e., dyspnea, palpitations, tachycardia, hypotension, itching, and urticaria). Emergency drugs should be available.

Posttest

- Observe for delayed allergic reaction to the contrast dye (i.e., skin rash, urticaria, headache, vomiting, and/or renal dysfunction). Increased creatinine level can follow IV contrast use. An oral antihistamine may be ordered for mild reactions.
- If contrast dye has been used, instruct the patient to increase fluid intake to enhance the excretion of the dye.
- Be supportive of the patient and family. A CT scan can be frightening. The major risk involved is an allergic reaction to the dye (not common with nonionic contrast).

Patient Teaching

- Instruct the patient to resume his or her usual level of activity and diet, unless otherwise indicated.

Bony Pelvis, Long Bone, and Joint CT

- The nuclear medicine study to locate “hot areas” should be done before CT scan of the bones and joints.

Factors Affecting Diagnostic Results

- Barium sulfate can obscure visualization of the abdominal organs. Barium studies should be performed 4 days before the CT or after the CT.
- Excessive flatus can cause patient discomfort and may cause an inaccurate reading.
- Movement can cause artifacts.
- Metal plates in skull and metal bridges.
- Dental fillings.

Coombs Direct (Blood [RBCs])

Direct Antiglobulin Test

Reference Values

Adult: Negative.

Child: Negative.

Description

This test can identify a weak antigen–antibody reaction even when there is no visible RBC agglutination. A positive Coombs test reveals antibodies present in RBCs, but the test does not identify the antibody responsible.

This test is useful for diagnosing early erythroblastosis fetalis (hemolytic disease of newborns), autoimmune hemolytic anemia, hemolytic transfusion reaction, and some drug sensitizations (i.e., to levodopa and methyldopa).

The direct Coombs test is also known as the direct antiglobulin test, a method of detecting in vivo sensitization of RBCs.

Purpose

- To detect antibodies on RBCs that may cause cellular damage.

Coombs Indirect (Serum)

Reference Values

Adult: Negative.

Child: Negative.

Description

The Coombs indirect test can detect free circulating antibodies in the patient's serum. This test is done in crossmatching blood for transfusions to prevent a transfusion reaction to incompatible blood caused by minor blood-type factors. As a result of previous transfusions, a recipient's blood may contain specific antibody (antibodies) that could cause a transfusion reaction.

The indirect Coombs test is also known as the indirect antiglobulin test, a method of detecting in vitro sensitization of RBCs.

Purpose

- To check recipient and donor blood for antibodies prior to a blood transfusion.

C-reactive Protein (CRP) (Serum) and N High Sensitivity CRP (hs CRP)

Reference Values

Adult: Not usually present. *Qualitative*: Greater than 1.2 titer. *Positive*: Quantitative: 20 mg/dL.

Child: Not usually present.

N High Sensitivity CRP (hs CRP):

Adult: Less than 0.175 mg/L.

Description

C-reactive protein (CRP) is produced in the liver in response to tissue injury and inflammation. It appears in the blood

6–10 hours after an acute inflammatory process and tissue destruction, and it peaks within 48–72 hours. The serum CRP usually decreases after the third day of injury. Serum CRP is also found in many body fluids (i.e., pleural, peritoneal, and synovial fluids).

This type of protein is needed to fight injury and infection. Inflammation can cause the protein to become an inflammatory protein. Many references state that the inflammatory protein is an important factor in cardiovascular disease.

Chronic infection, fat cells, hypertension, smoking, cardiovascular and peripheral disease, stroke, and rheumatoid arthritis can produce these inflammatory proteins, which weaken the fatty plaques and cause eruption. The pieces of plaques become clots, which lead to decreased blood flow and even heart attacks. Higher levels of inflammatory proteins in the blood indicate a higher potential for atherosclerosis.

N High Sensitivity CRP (hs CRP)

This test is a highly sensitive test for detecting the risk of cardiovascular and peripheral vascular diseases. It is frequently combined with cholesterol screening. Approximately one third of those who have had a heart attack have normal cholesterol levels and normal blood pressure. A positive hs CRP test may indicate that the patient is at a high risk for coronary artery disease (CAD) and stroke. The CRP does not elevate in cases of angina pectoris. This test can detect an inflammatory process that is caused by the buildup of plaque (atherosclerosis) in the arterial system, particularly the coronary arteries. Positive serum hs CRP values are much lower than the standard serum CRP, which makes it a more valuable test for predicting coronary heart disease.

Purpose

- To detect the risk of coronary heart disease.
- To associate an increased CRP titer with an acute inflammatory process.
- To compare results with other laboratory tests.

Creatine Phosphokinase (CPK) (Serum), CPK Isoenzymes (Serum)

Creatine Kinase (CK)

Reference Values

Adult: *Male*: 5–35 mcg/mL, 30–180 international unit/L, 55–170 unit/L at 37°C (SI units). *Female*: 5–25 mcg/mL, 25–150 international unit/L, 30–135 unit/L at 37°C (SI units).

Child: *Newborn*: 65–580 international unit/L at 30°C. *Child: Male*: 0–70 international unit/L at 30°C. *Female*: 0–50 international unit/L at 30°C.

CPK Isoenzymes:

CPK-MM: 94–100%	(muscle)
CPK-MB: 0–6%	(heart)
CPK-BB: 0%	(brain)

Most labs have replaced CPK isoenzymes with CPK-MB fraction only.

Description

Creatine phosphokinase (CPK), also known as creatine kinase (CK), is an enzyme found in high concentration in heart and skeletal muscles and in low concentration in brain tissue. Serum CPK/CK is frequently elevated by skeletal muscle disease, acute myocardial infarction (MI), cerebrovascular disease, vigorous exercise, intramuscular (IM) injections, and electrolyte imbalance hypokalemia. CPK/CK has two types of isoenzymes: M, associated with muscle, and B, associated with the brain. Electrophoresis separates the isoenzymes into three subdivisions: MM (in skeletal muscle and some in the heart), MB (in the heart), and BB (in brain tissue). When CPK/CK is elevated, a CPK electrophoresis is done to determine which group of isoenzymes is elevated. Increased isoenzyme CPK-MB could indicate damage to the myocardial cells.

Serum CPK/CK and CPK-MB rise within 4–6 hours after an acute MI, reach a peak in 18–24 hours (greater than 6 times the normal value), and then return to normal within 3–4 days, unless new necrosis or tissue damage occurs. If medication for acute MI has to be given parenterally (for instance, morphine), it would be better to give it intravenously than intramuscularly so that mild muscle injury (from IM) would not elevate the CPK level; however, injections have little or no effect on CPK-MB. Draw blood for a serum CPK/CK level before giving an IM injection.

Purpose

- To suggest myocardial or skeletal muscle disease.
- To compare test results with AST and LD levels to determine myocardial damage.

Creatinine (Serum)

Reference Values

Adult: 0.5–1.5 mg/dL, 45–132.3 $\mu\text{mol/L}$ (SI units). Women may have slightly lower values because of their lesser muscle mass.

Child: *Newborn*: 0.8–1.4 mg/dL. *Infant*: 0.7–1.7 mg/dL. *Child (2–6 Years)*: 0.3–0.6 mg/dL, 27–54 $\mu\text{mol/L}$ (SI units). *Older Child*: 0.4–1.2 mg/dL, 36–106 $\mu\text{mol/L}$ (SI units). Values increase slightly with age relative to muscle mass.

Older Adult: May have decreased values relative to decreased muscle mass and decreased creatinine production.

Description

Creatinine, a by-product of muscle catabolism, is derived from the breakdown of muscle creatine phosphate. The amount of creatinine produced is proportional to the muscle mass. Creatinine is filtered by the glomeruli and is excreted in the urine.

Serum creatinine is considered a more sensitive and specific indicator of renal disease than blood urea nitrogen (BUN). It rises later and is not influenced by diet or fluid intake. A slight BUN elevation could be indicative of hypovolemia (fluid volume deficit); however, a serum creatinine of 2.5 mg/dL could be indicative of renal impairment. BUN and creatinine are frequently compared. If BUN increases

and serum creatinine remains normal, dehydration (hypovolemia) is present; if both increase, then renal disorder is present. Serum creatinine is especially useful in evaluation of glomerular function.

Purpose

- To diagnose renal dysfunction.

Creatinine Clearance (Urine)

Creatinine (Urine)

Reference Values

Adult: 85–135 mL/min. Women may have somewhat lower values.

Child: Similar to adult. *Newborn*: 40–60 mL/min.

Older Adult: Slightly decreased values than adult due to decreased glomerular filtration rate (GFR) caused by reduced renal plasma flow.

Urine Creatinine: 1–2 g/24 h.

Description

Creatinine is a metabolic product of creatine phosphate in skeletal muscle, and it is excreted by the kidneys. Creatinine clearance is considered a reliable test for estimating GFR. With renal insufficiency, the GFR is decreased, and the serum creatinine is increased. GFR decreases with age, and in the older adult, creatinine clearance may be diminished to as low as 60 mL/min.

The creatinine clearance test consists of a 12- or 24-hour urine collection and a blood sample.

The formula for calculating the creatinine clearance test is:

$$\text{Creatinine clearance} = \frac{\text{Urine creatinine (mcg/dL)} \times \text{Urine volume (dL)}}{\text{Serum creatinine (mcg/dL)}}$$

A creatinine clearance of less than 40 mL/min is suggestive of moderate to severe renal impairment.

Purpose

- To detect renal dysfunction.
- To monitor renal function.

Crossmatching (Blood)

Blood Typing Tests, Compatibility Test for RBCs, Type and Crossmatch

Reference Values

Adult: Compatibility; absence of agglutination (clumping) of cells.

Child: Same as adult.

Description

The four *major* blood types (A, B, AB, and O) belong to the ABO blood group system. Red blood cells (RBCs) can have antigen A, B, AB, or none on the surface of the cells. Type A has A antigen, B has B antigen, AB has A and B antigens, and O does not contain an antigen. These antigens are capable of

producing antibodies. The AB blood individual is the universal recipient (can accept all blood), because there are no antibodies; the O blood person is the universal donor (can give blood to all types).

ABO blood type and Rh factor are first determined, then the compatibility of donor and recipient blood is determined via major crossmatching. The major crossmatch is between the donor's RBCs and the recipient's serum.

Purpose

- To determine blood type.
- To determine if the recipient has any antibodies to destroy the donor's RBCs.

Factors Affecting Laboratory Results

- Previously received incompatible blood can make blood crossmatching difficult.

Cultures (Blood, Sputum, Stool, Throat, Wound, Urine)

Reference Values

Adult: Negative or no pathogen.

Child: Same as adult.

Description

Cultures are taken to isolate the microorganism that is causing the clinical infection. Most culture specimens are obtained using sterile swabs with medium (solid or broth), a sterile container (cup) with a lid, and a sterile syringe with a sterile bottle of liquid medium. The culture specimen should be taken immediately to the laboratory after collection (no longer than 30 minutes), because some organisms will die if not placed in the proper medium and incubated.

Most specimens for culture are blood, sputum, stool, throat secretions, urine, or wound exudate. It usually takes 24–36 hours to grow the organisms and 48 hours for the growth and culture report.

Purpose

- To isolate the microorganism in body tissue or body fluid.

Clinical Problems

Specimen	Clinical Condition or Most Commonly Isolated Organism
Blood	Bacteremia, septicemia, postoperative shock, fever of unknown origin
Sputum	Pulmonary tuberculosis, bacterial pneumonia, chronic bronchitis, bronchiectasis
Stool	<i>Salmonella</i> species, <i>Shigella</i> species, enteropathogenic <i>Escherichia coli</i> , <i>Staphylococcus</i> species, <i>Yersinia</i>
Throat	Beta-hemolytic streptococci (rheumatic fever), thrush (<i>Candida</i> species), tonsillar infection, <i>Staphylococcus aureus</i>
Urine	<i>Escherichia coli</i> , <i>Klebsiella</i> species, <i>Pseudomonas aeruginosa</i> , <i>Serratia</i> species, <i>Shigella</i> species; yeasts: <i>Candida</i> species
Wound	<i>Staphylococcus</i> species: <i>S. aureus</i> , <i>Pseudomonas aeruginosa</i> , <i>Proteus</i> species, <i>Bacteroides</i> species, <i>Klebsiella</i> species, <i>Serratia</i> species

Procedure

- Hand hygiene is essential before and after collection of the specimen.
- Send the specimen for culture to the laboratory *immediately* after collection.
- Obtain the specimen before antibiotic therapy is started. If the patient is receiving antibiotics, the drug(s) should be listed on the laboratory slip.
- Collection containers or tubes should be sterile. Aseptic technique should be used during collection. Contamination of the specimen could cause false-positive results and/or transmission of the organisms.
- Check with the laboratory for specific techniques used.

Blood: Cleanse the patient's skin according to the institution's procedure. Usually the skin is scrubbed first with povidone-iodine (Betadine). Iodine can be irritating to the skin; if irritation occurs, the solution is removed and benzalkonium chloride or alcohol is applied. Cleanse the top(s) of the culture bottle(s) with iodine and leave it or them to dry. The bottle(s) should contain a culture medium. Collect 5–10 mL of venous blood and place in the sterile bottle. Special vacuum tubes containing a culture medium for blood may be used instead of a culture bottle.

Sputum: Sterile Container or Cup: Obtain sputum for culture early in the morning, before breakfast. Instruct the patient to give several deep coughs to raise sputum. Tell the patient to avoid spitting saliva secretion into the sterile container. Saliva and postnasal drip secretions can contaminate the sputum specimen. Keep a lid on the sterile container. The container *should not* be completely filled and should be taken immediately to the laboratory. The sputum sample should not remain for hours by the patient's bedside unless one needs a 24-hour sputum specimen (in this case, an extra sterile container should be left). **Acid-Fast Bacilli (TB Culture):** Follow the instructions on the container. Collect 5–10 mL of sputum, and take the sample immediately to the laboratory or refrigerate the specimen. Three sputum specimens may be requested, one each day for 3 days. Check for proper labeling.

Stool: Collect an approximately 1-inch-diameter feces sample. Use a sterile tongue blade and place the stool specimen in a sterile container with a lid. The suspected disease or organism should be noted on the laboratory slip. The stool specimen should not contain urine. The patient should not be given barium or mineral oil, which can inhibit bacteria growth.

Throat: Use a sterile cotton swab or a polyester-tipped swab. The sterile culture kit could be used. Swab the inflamed or ulcerated tonsillar and/or postpharyngeal areas of the throat. Place the applicator in a culturette tube with its culture medium. Take the throat culture specimen immediately to the laboratory. Do *not* give antibiotics before taking the culture.

Wound: Use a culture kit containing a sterile cotton swab or a polyester-tipped swab and a tube with culture medium. Swab the exudate of the wound and place the swab in the tube containing a culture medium. Wear

sterile gloves when there is an excess amount of purulent drainage.

Urine: Clean-Caught (Midstream) Urine Specimen: Clean-caught urine collection is the most common method for collecting a urine specimen for culture. Noncatheterization kits are available that give step-by-step instructions. Catheterizing for urine culture is seldom ordered. Usually the patient collects the urine specimen for culture, so a detailed explanation should be given, according to the instructions. The penis or vulva should be well cleansed. At times, two urine specimens (2–10 mL) are requested to verify the organism and in case of a possible contamination of the urine specimen. Collect a midstream urine specimen early in the morning, or as ordered, in a sterile container. The lid should fit tightly on the container and the urine specimen should be taken immediately to the bacteriology laboratory or be refrigerated. Label the urine specimen with the patient's name, the date, and the exact time of collection (e.g., 7/22/15 @ 8:00 a.m.). List any antibiotics or sulfonamides the patient is taking on the laboratory slip.

Factors Affecting Laboratory Results for Cultures

- Contamination of the specimen causes inaccurate results.
- Antibiotics and sulfonamides may cause false-negative results.
- Urine in the stool collection may cause false test results.

Cystoscopy, Cystography (Cystogram)

Normal Findings

Normal structure of the urethra, bladder, prostatic urethra, and ureter orifices.

Description

Cystoscopy is the direct visualization of the bladder wall and urethra with the use of a cystoscope (a tubular, lighted telescopic lens). Usually this diagnostic test is performed by a urologist. Small renal calculi can be removed from the ureter, bladder, or urethra with this procedure, and a tissue biopsy can be obtained. In addition, *retrograde pyelography* (injection of contrast dye through the catheter into the ureters and renal pelvis) may be performed during the cystoscopy.

Cystoscopy is performed in a cystoscopy room of a hospital or in a urologist's office under general or local anesthesia. Premedications are administered an hour prior to the test.

Cystography is the instillation of a contrast dye into the bladder via a catheter. This procedure can detect a rupture in the bladder, a neurogenic bladder, fistulas, and tumors. The test is useful when x-rays are needed and a cystoscopy or retrograde pyelography is contraindicated.

Purposes

- To detect renal calculi and renal tumor.
- To remove renal stones.

Nursing Implications with Rationale Cystoscopy, Cystography (Cystogram)

Pretest

- Obtain history concerning the presence of cystitis or prostatitis, which could result in sepsis.
- Explain the procedure to the patient. Answer questions or refer questions you cannot answer to the urologist.
- Check with the urologist about the form of anesthesia the patient will receive—local or general. If a local anesthetic is to be used, inform the patient that it will be injected into the urethra several minutes before the cystoscope is inserted.
- Check that the consent form has been signed before administering the premedications. Normally the drugs are given 1 hour before the test.
- Check with the patient concerning hypersensitivity to anesthetics.
- Assess urinary patterns, such as amount, color, odor, specific gravity of the urine.
- Take baseline vital signs.

Patient Teaching

- Inform the patient that there may be some pressure or burning discomfort during and/or following the test.

Posttest

- Recognize the complications that can occur as a result of the cystoscopy, such as hemorrhaging, perforation of the bladder, urinary retention, and infection.

- Monitor vital signs (VS). Compare with baseline VS. VS may be ordered every half hour until stable.
- Monitor the urinary output for 48 hours following a cystoscopy. If urine output is less than 200 mL in 8 hours, encourage fluid intake. Anuria could indicate urinary retention due to blood clots or urethral stricture. Report findings to the urologist. An indwelling catheter may be ordered.
- Report and record gross hematuria. Inform the patient that blood-tinged urine is not uncommon after a cystoscopic examination.
- Observe for signs and symptoms of an infection (i.e., fever, chills, an increased pulse rate, and pain). Antibiotics may be given before and after the test as a prophylactic measure.
- Apply heat to the lower abdomen to relieve pain and muscle spasm as ordered.

Patient Teaching

- Advise the patient to avoid alcoholic beverages for 2 days after the test.
- Instruct the patient to increase water intake for several days after the test.
- Inform the patient that a slight burning sensation when voiding for a day or two is considered normal. Usually the urologist leaves an order for an analgesic.

- To determine the cause of hematuria or urinary tract infection (UTI).

Procedure

- A consent form should be signed.
- The patient can have a full liquid breakfast the morning of the test if local anesthetic is used. Several glasses of water may be ordered. If general anesthesia is to be administered, the patient should be NPO for 8 hours before cystoscopy.
- Record baseline vital signs.
- A narcotic analgesic (meperidine, morphine) may be ordered an hour before the cystoscopy. The procedure is done under local or general anesthesia.
- The patient is placed in a lithotomy position (feet or legs in stirrups). A local anesthetic is injected into the urethra. Water may be instilled to enhance better visualization. A urine specimen may be obtained.
- The cystoscopy takes approximately 30 minutes to 1 hour.

D-Dimer Test (Blood)

Fragment D-Dimer, Fibrin Degradation Fragment

Reference Values

Negative for D-dimer fragments: Greater than 250 ng/mL, greater than 250 mcg/L (SI units).

Description

D-dimer, a fibrin degradation fragment, occurs through fibrinolysis. This test measures the amount of fibrin degradation that occurs. It confirms the presence of fibrin split products (FSPs) and is more specific for diagnosing disseminated intravascular coagulation (DIC) than FSPs. However, both D-dimer and FSP tests are frequently used to determine DIC in a patient.

D-dimer levels are increased when a fibrin clot is broken down by the thrombolytic drug, tissue plasminogen activator (tPA), streptokinase.

Purpose

- To detect the presence of DIC in a patient.

Digoxin (Serum)

Lanoxin

Reference Values

Therapeutic: *Adult*: 0.5–2 ng/mL, 0.5–2 nmol/L (SI units). *Infants*: 1–3 ng/mL. *Child*: Same as adult.

Toxic: *Adult*: Greater than 2 ng/mL, greater than 2.6 nmol/L (SI units). *Infants*: Greater than 3.5 ng/mL. *Child*: Same as adult.

Description

Digoxin, a form of digitalis, is a cardiac glycoside agent given to increase the force and velocity of myocardial contraction. More than 75–95% of the drug is absorbed through the gastrointestinal (GI) tract, and a large amount of digoxin

is excreted unchanged through the kidneys. The half-life of digoxin is 35–40 hours, with a shorter half-life in neonates and infants and a longer time in short-term infants/premature infants.

Serum plateau levels of digoxin occur 6–8 hours after an oral dose, 2–4 hours after IV administration, and 10–12 hours after IM administration. The most frequent routes used for administering digoxin are by mouth (oral) and IV.

Electrolyte imbalance (hypokalemia or hypomagnesemia), acid-base disturbances, and certain drugs predispose the person to digitalis toxicity. Common signs and symptoms of digitalis toxicity include pulse rate less than 60 per minute, anorexia, nausea, vomiting, headaches, and visual disturbance.

Purpose

- To monitor digoxin levels.

Factors Affecting Laboratory Results

- Administering digoxin intramuscularly might cause the absorption rate to be erratic, especially in a debilitated individual or older adult with poor tissue perfusion.
- A low serum potassium or magnesium level could cause digitalis toxicity, and a high serum calcium level could also cause digitalis toxicity.
- Hypothyroidism, severe heart disease, and renal function abnormalities may predispose a patient to digitalis toxicity.

Echocardiography (Echocardiogram)

M-Mode, Two-Dimensional (2D), Spectral Doppler, Color Flow Doppler, Transesophageal, Contrast, and Stress Echocardiography

Normal Findings

Normal heart size and structure; normal movements of heart valves and heart chambers.

Description

Echocardiography (echocardiogram) is a noninvasive ultrasound test. A handheld transducer (probe) is moved over the chest in the area of the heart and other specified surrounding areas. The transducer sends and receives high-frequency sound waves. The sound waves that are reflected (echo) from the heart back to the transducer produce pictures. These pictures appear on a television-like screen and are recorded on video and moving graph paper.

The various types of echocardiographic studies include M-mode, two-dimensional (2D), spectral Doppler, color Doppler, transesophageal, contrast, and stress echocardiography. Transesophageal echocardiography (TEE) is gaining popularity for diagnosing and managing a wide range of cardiovascular diseases, such as valvular heart dysfunction and aortic pathology. Stress echocardiography is a valuable tool for assessing myocardial ischemia at half the cost of other cardiac studies.

M-Mode Echocardiography

M-mode echocardiography, the earliest type of echocardiography, is used to record the motion of various heart structures

B-32 Appendix B Diagnostic Values and Laboratory Tests

(M is for *motion*). This test assesses the dimension of the left ventricle and its degree of dilation and contractility related to myocardial disease or volume overload. It is useful for measuring the thickness of the right and left ventricles (hypertrophy). M-mode echocardiography is also used for assessing the cardiac valves and valvular movements for stenosis, regurgitation, or prolapse.

Two-Dimensional (2D) Echocardiography

This test employs M-mode echocardiography, which records motion, and provides 2D (cross-sectional) views of the heart structures. It is used to evaluate the size, shape, and movement of the chambers and valves of the heart and it is useful in detecting valvular disease and in assessing congenital heart disease.

Spectral Doppler Echocardiography

Spectral Doppler echocardiography measures the amount, speed, and direction of blood passing through the heart's valves and chambers. A swishing sound is heard as the blood flows throughout the heart. This test can detect turbulent blood flow through the heart valves, which may indicate valvular disease. Septal wall defects may also be detected.

Color Doppler Echocardiography

Color Doppler (red and blue) echocardiography shows the direction of blood flowing through the heart. It can identify leaking heart valves (regurgitation) or hardened valves (stenosis), malfunction of prosthetic valves, and the presence of shunts (holes) in the heart. The use of the color Doppler study complements 2D echocardiography and the spectral Doppler study.

Transesophageal Echocardiography

With transesophageal echocardiography (TEE), a transducer (probe) is attached to an endoscope and inserted into the esophagus to visualize adjacent cardiac and extracardiac structures with greater acuity than most echocardiography studies, including transthoracic (TTE). TEE can be used in the intensive care unit, emergency department, and operating room, as well as in cardiac testing facilities. This type of echocardiography is useful for diagnosing mitral and aortic valvular pathology; determining the presence of a possible intracardiac thrombus in the left atrium; detecting suspected acute dissection of the aorta and endocarditis; monitoring left ventricular function before, during, or after surgery; and evaluating intracardiac repairs during surgery.

This test is contraindicated if esophageal pathology (e.g., strictures, varices, trauma) exists. Also, TEE should not be performed if undiagnosed active gastrointestinal bleeding is occurring or if the patient is uncooperative. A light sedative is frequently given prior to testing. TEE can be performed on an unconscious patient. TEE is tolerated well, with approximately 1% of patients being intolerant of the esophageal probe. The rate of complications is less than 0.2%.

Contrast Echocardiography

This test assists in determining intracardiac communications, myocardial ischemia, and perfusion defects. Microbubbles

are injected into the venous circulation for the purpose of recording showers of echoes by M-mode or 2D tests. The microbubbles pass through the right atrium and ventricle, where they are absorbed in the lung; they do not pass to the left side of the heart. If the microbubbles are detected on the left side of the heart, an intracardiac communication or shunt is present. New contrast agents may allow visualization of the coronary arteries and perfusion to the myocardium with echocardiography.

Stress Echocardiography

It may be necessary to evaluate the function of the left ventricle under stress. A baseline 2D and Doppler echocardiogram is performed. The patient then exercises until the predicted maximum heart rate is achieved, symptoms appear, or electrocardiographic or echocardiographic signs of myocardial ischemia occur. Immediately after exercising, the heart's reimage is compared to baseline for any wall motion changes.

The stress modalities used in conjunction with echocardiography include exercise and IV administration of an agent that either increases myocardial oxygen consumption, such as dobutamine or arbutamine, or induces myocardial heterogeneity, such as dipyridamole or adenosine.

Purpose

- To identify abnormal heart size, structure, ischemia, function and valvular disease.

Procedure

- A consent form should be signed.
- Food and fluids are not restricted.
- No medications should be omitted before the test unless indicated by the institution or healthcare provider.
- The patient undresses from waist up and wears a hospital gown. For the test, the patient will be positioned on his or her left side or in the supine position.
- Vital signs are recorded. Three electrode patches are applied to the chest area to monitor heart rate and changes in cardiac rhythm.
- Water-soluble gel is applied to the skin areas that are to be scanned. The transducer (probe), with slight pressure, is moved over different areas of the chest. Some patients may require that pictures be taken under the neck.
- The 2D echo takes about 20 to 30 minutes, and the 2D echo with Doppler studies takes approximately 30 to 45 minutes.
- The cardiologist interprets the test results and submits a report to the patient's healthcare provider, who gives the test results to the patient.

Transesophageal Echocardiography (TEE)

- The patient should be NPO for at least 4 hours prior to the test.
- A light IV sedative (e.g., Versed) is given prior to the test.
- The endoscopic transducer is inserted into the esophagus.

- The test takes 15–30 minutes.
- The patient is monitored (Dynamap) during recovery for 1–2 hours.

Contrast Echocardiography

- An IV line is inserted for injection of contrast media.

Stress Echocardiography

- The patient should be NPO for 4 hours before the test.
- The patient may be placed on a treadmill or receive a pharmacologic agent.
- Images are acquired during rest (pretest) and then during stress or immediately following stress (posttest).

Factors Affecting Diagnostic Results

- Large body habitus may cause poor image quality.
- Severe respiratory disease may affect test results.

Electrocardiography (Electrocardiogram—ECG or EKG), Vectorcardiography (Vectorcardiogram—VCG)

Normal Findings

Normal electrocardiogram deflections (P, PR, QRS, ST, and T).

Description

An electrocardiogram (ECG) records the electrical impulses of the heart by means of electrodes and a galvanometer (ECG machine). These electrodes are placed on the legs, arms, and chest. Combinations of two electrodes are called bipolar leads (i.e., lead I is the combination of both arm electrodes, lead II is the combination of the right-arm and left-leg electrodes, and lead III is the combination of the left-arm and left-leg electrodes). The unipolar leads are AVF, AVL, and AVR, where the A means augmented, V is the voltage, and F is left foot, L is left arm, and R is right arm. At least six unipolar chest or precordial leads are used. A standard ECG consists of 12 leads: six limb leads (I, II, III, AVF, AVL, AVR) and six chest (precordial) leads (V₁, V₂, V₃, V₄, V₅, V₆).

With each cardiac cycle or heartbeat, the sinoatrial node (SA or sinus node) sends an electrical impulse through the atrium, causing atrial contraction or atrial depolarization. The SA node is called the pacemaker, because it controls the heartbeat. The impulse is then transmitted to the atrioventricular (AV) node and the bundle of His and travels down the ventricles, causing ventricular contraction or ventricular depolarization. When the atria and the ventricles relax, repolarization and recovery occur.

The electrical activity that the ECG records is in the form of waves and complexes: P wave (atrial depolarization); QRS complex (ventricular depolarization); and ST segment, T wave, and U wave (ventricular repolarization). An abnormal ECG indicates a disturbance in the electrical activity of the myocardium. Therefore, an individual could have heart disease yet have a normal ECG if the individual's cardiac problem does not affect the transmission of electrical impulses.

Nursing Implications with Rationale Electrocardiography

- Record the list of medications the patient is taking. The healthcare provider may want to compare ECG readings to check for improvement and changes; therefore, knowing the drugs the patient is taking at the time of the ECG would be helpful.

Patient Teaching

- Instruct the patient to relax and to breathe normally during the ECG procedure. Tell the patient to avoid tightening the muscles, grasping bedrails or other objects, and talking during the ECG tracing.
- Tell the patient that the ECG should not cause pain or any great discomfort.
- Ask the patient to tell you if he or she is having chest pain during the ECG tracing. Mark the ECG paper at the time the patient is having chest pain.
- Allow the patient time to ask questions. Refer questions you cannot answer to another healthcare provider, for example, a physician or cardiologist.
- Inform the patient that the ECG takes about 15 minutes.

Posttest

- Remove the electropaste or jelly, if used, from the electrode sites when the ECG is completed. Assist the patient with dressing, if necessary.

Vectorcardiogram (VCG)

The VCG records electrical impulses from the cardiac cycle, making it similar to the ECG. However, it shows a 3D view (frontal, horizontal, and sagittal planes) of the heart, whereas the ECG shows a 2D view (frontal and horizontal planes). The VCG is considered more sensitive than the ECG for diagnosing a myocardial infarction. It is useful for assessing ventricular hypertrophy in adults and children.

Purpose

- To detect cardiac dysrhythmias.
- To identify electrolyte imbalance (e.g., hyperkalemia [peaked T wave]).
- To monitor ECG changes during the stress/exercise tests and the recovery phase after a myocardial infarction.

Procedure

- Food, fluids, and medications are not restricted, unless otherwise indicated.
- Clothing should be removed to the waist, and the female patient should wear a gown.
- Nylon stockings should be removed, and trouser bottoms should be raised.
- The patient should lie in a supine position.
- The skin surface should be prepared. Excess hair should be shaved from the chest if necessary.
- Electrodes with electropaste or pads are strapped to the four extremities. The color-coded lead wires are inserted

B-34 Appendix B Diagnostic Values and Laboratory Tests

into the correct electrodes. Chest electrodes are applied. The lead selector is turned to record the 12 standard leads unless the ECG machine automatically records the lead strips.

- The ECG takes approximately 15 minutes.

Factors Affecting Diagnostic Results

- Body movement and electromagnetic interference during the ECG recording could distort the tracing.
- Poor electrode-to-skin contact will distort tracing.

Electroencephalography (Electroencephalogram—EEG)

Description

The electroencephalogram (EEG) measures the electrical impulses produced by brain cells. Electrodes, applied to the scalp surface at predetermined measured positions, record brain-wave activity on moving paper. At times, recorded brain waves may be normal when there is pathology.

If the EEG recording gives a flat or straight line for many hours, this usually indicates severe hypoxia and brain death. The cardiovascular functions are usually being maintained through the use of life-support systems (e.g., a respirator, oxygen, and IVs). The neurologist interprets the EEG readings and gives suggestions.

Purpose

- To detect patterns characteristic of some diseases (i.e., seizure disorders, neoplasms, cerebrovascular accidents, head trauma, and infections of the nervous system)
- To assist in the determination of cerebral death.

Procedure

The procedure may be performed while the patient is (1) awake, (2) drowsy, (3) asleep, or (4) undergoing stimuli (hyperventilation or rhythmic flashes of bright light), or (5) a combination of any of these.

Pretest

- The hair should be shampooed the night before the test. Instruct the patient not to use oil or hair spray on the hair.
- The decision concerning withdrawal of medications before the EEG is made by the healthcare provider. Sleeping pills and other sedatives may not be given the night before the test because they can affect the EEG recording.
- Food and fluids are not restricted, except *no* coffee, tea, cola, or alcohol before the test.
- The EEG tracing is usually obtained with the patient lying down; however, the patient could be seated in a reclining chair.
- For a sleep recording, keep the patient awake 2–3 hours later the night before the test and wake the patient up at 6 a.m. A sedative such as chloral hydrate may be ordered.
- The EEG test takes approximately 1.5–2 hours. Flat electrodes will be applied to the scalp.

Posttest

- Remove the collodion or paste from the patient's head. Acetone may be used to remove the paste.
- The patient should resume normal activity unless he or she has been sedated.

Factors Affecting Diagnostic Results

- Drugs (i.e., sedatives, barbiturates, anticonvulsants, and tranquilizers) can affect test results.
- Alcohol could decrease cerebral impulses.
- Oily hair or the use of hair spray can affect test results.

Electromyography (Electromyogram—EMG)

Normal Findings

At Rest: Minimal electrical activity.

Voluntary Muscle Contraction: Markedly increased electrical activity.

Description

Electromyography (EMG) measures the electrical activity of skeletal muscles at rest and during voluntary muscle contraction. A needle electrode is inserted into the skeletal muscle to pick up electrical activity, which can be heard over a loudspeaker, viewed on an oscilloscope, and recorded on graphic paper all at the same time. Normally there is no electrical activity when the muscle is at rest; however, in motor disorders abnormal patterns can occur. With voluntary muscle contraction, a loud popping sound is heard and increased electrical activity (wave) is recorded.

Purpose

- To diagnose neuromuscular disorders such as muscular dystrophy.

The test is useful in diagnosing neuromuscular disorders. The EMG can be used to differentiate between myopathy and neuropathy.

Procedure

- A consent form should be signed.
- Food and fluids are not restricted, with the exceptions of *no* coffee, tea, colas, or other caffeine drinks, and *no* smoking for at least 3 hours before the EMG.
- Medications such as muscle relaxants, anticholinergics, and cholinergics should be withheld before the test with the approval of the healthcare provider. If the patient needs the specific medication, the time for the test should be rearranged.
- The patient lies on a table or stretcher or sits in a chair in a room free of noise. The EMG takes 1 hour, but could take longer if a group of muscles is to be tested.
- Needle electrodes are inserted in selected or affected muscles. If the patient experiences pain, the needle should be removed and reinserted.

Nursing Implications with Rationale Electroencephalography

- A consent form should be signed.
- Explain the procedure to the patient, step by step. List the important steps on paper for the patient if needed.
- Report if the patient is taking medications that could change the EEG result.
- Check with the healthcare provider and/or EEG department with regard to the type(s) of recordings ordered (i.e., awake, sleep, stimuli).
- Be supportive of the patient. Answer questions and permit the patient to express concerns.
- Report to the healthcare provider and inform the EEG laboratory if the patient is extremely anxious, restless, or upset.
- Observe for seizures and describe the seizure activity—the movements and how long they last. Have a tongue blade by the bedside at all times. Chart all seizure activity and the time of its occurrence, because it is very important for the technologist and electroencephalographer to know this.

Patient Teaching

- Inform the patient that he or she will *not* get an electric shock from the machine (electroencephalograph) and that the machine does not determine the patient's intelligence and cannot read the patient's mind. Many patients are apprehensive and fearful of this test.
- Encourage the patient to eat a meal before the test. Hypoglycemia should be prevented because it can affect normal brain activity. Coffee, tea, cola, and any other stimulants should be avoided. Alcohol should also be avoided; it is a depressant and can affect the test result.
- Inform the patient that the test does not produce pain.
- Advise the patient to be calm and to relax during the test. If rest and stimuli (flashing lights) recordings are ordered, inform the patient that there will be a brief time when there are flashing lights. Prepare the patient, but do not increase the patient's apprehension, if possible.
- Inform the patient that the test takes 1.5–2 hours. The room is quiet where the EEG recording is made and is conducive to rest and sleep.
- Instruct the patient, after the test, that normal activity can be resumed.

- If serum enzyme tests are ordered (i.e., AST [SGOT], CPK, LDH), the samples should be drawn before the EMG or 5–10 days after the test.

Posttest

- If residual pain occurs, analgesic may be given.

Factors Affecting Diagnostic Results

- Pain could cause false reports.
- Age of the patient: Electrical activity may be decreased in some older adults.
- Drugs: Muscle relaxants, anticholinergics, and cholinergics could affect the results.
- Fluids that contain caffeine can affect results.

Erythrocyte Sedimentation Rate (ESR) (Blood)

Sedimentation (SED) Rate

Reference Values

Adult: *Westergren Method: Male (Less Than 50 Years):* 0–15 mm/h. *Female (Less Than 50 Years):* 0–20 mm/h. *Male (Greater Than 50 Years):* 0–20 mm/h. *Female (Greater Than 50 Years):* 0–30 mm/h. *Wintrobe Method: Male:* 0–9 mm/h. *Female:* 0–15 mm/h.

Child: *Newborn:* 0–2 mm/h. *Child (4–14 Years):* 0–10 mm/h.

Description

The erythrocyte sedimentation rate (ESR), also known as the sedimentation rate or SED rate, is the rate at which red blood cells (RBCs) settle in unclotted blood in millimeters per hour (mm/h). The ESR is nonspecific. The rate can be increased in acute inflammatory process, acute and chronic infections, tissue damage (necrosis), rheumatoid arthritis, collagen diseases, malignancies, and physiologic stress situations (e.g., pregnancy). To some hematologists, the ESR is unreliable, because it is nonspecific and is affected by physiologic factors that cause inaccurate results.

The C-reactive protein (CRP) test is considered more useful than the ESR because CRP increases more rapidly during an acute inflammatory process and returns to normal faster than the ESR. The ESR is still an old standby used by many physicians as a rough estimate of the disease process and for following the course of illness. With an elevated ESR, other laboratory tests should be conducted to properly identify the clinical problem.

Purpose

- To compare with other laboratory values for diagnosing inflammatory conditions.

Esophagogastroduodenoscopy, Esophagogastroscope

Gastroscopy, Esophagoscopy, Duodenoscopy, Endoscopy

Normal Findings

Normal mucous membranes of the esophagus, stomach, and duodenum; absence of pathology.

Description

Esophagogastroscope includes gastroscopy and esophagoscopy. If duodenoscopy is included with the endoscopic examination, the term is *esophagogastroduodenoscopy*. A flexible fiberoptic endoscope is used for direct visualization of the internal structures of the esophagus, stomach, and duodenum. Biopsy forceps or a cytology brush can also be inserted through a channel of the endoscope. Suction can be applied for the removal of secretions and foreign bodies.

This test is performed under local anesthesia or IV sedation (benzodiazepine or narcotics), in a gastroscopy room of a hospital or clinic, usually by a gastroenterologist. This procedure can be done on an emergency basis for removal of

Nursing Implications with Rationale

Esophagogastroduodenoscopy

- Recognize that a gastroscopy test for visualizing the esophageal, gastric, and duodenal mucosa is actually an esophagogastroduodenoscopy. These names are frequently used interchangeably.
- Check that the patient's dentures, eyeglasses, and jewelry are removed. Give the patient a hospital gown.
- Have the patient void. Take vital signs.
- Check that a consent form has been signed before giving the patient premedications. Once the sedative and the narcotic analgesic have been given, the patient should remain in bed with the bed sides up. Tell him or her that these medications will cause drowsiness.
- Be a good listener. Allow the patient time to ask questions and to express concerns or fears. Refer questions you cannot answer to the gastroenterologist or healthcare provider.
- Check that the patient has not had food or fluids for 8–12 hours before the tests.

Patient Teaching

- Explain the procedure to the patient. Inform the patient that the instrument is flexible; the procedure will be done under local anesthesia (the throat will be sprayed); premedications will be given before the test and usually IV sedation is given with the test; dentures and jewelry should be removed; and food and fluids will be restricted for 8–12 hours before the test.

- Explain to the patient that he or she may feel some pressure with the insertion of the endoscope and may feel some fullness in the stomach when air is injected for better visualization of the stomach and intestine areas.

Posttest

- Keep the patient NPO for 2–4 hours after the test or as ordered.
- Check the gag reflex before offering food and fluids by asking the patient to swallow or by touching the posterior pharynx with a cotton swab or tongue blade if the throat was sprayed with an anesthetic.
- Monitor vital signs (blood pressure, pulse, respirations) as ordered.
- Give the patient throat lozenges or analgesics for throat discomfort. Inform the patient that he or she may have flatus or “burp-up gas,” which is normal. This is caused by the instillation of air during the procedure for visualization purposes.
- Observe the patient for possible complications (e.g., perforation in the gastrointestinal tract from the endoscope). Symptoms could include pain (epigastric, abdominal, back pain), dyspnea, fever, tachycardia, and subcutaneous emphysema in the neck.
- Be supportive of the patient and family.

foreign objects (a bone, a pin, and so on) and for diagnostic purposes. The major complications that can occur from esophagogastroduodenoscopy are perforation and hemorrhage.

Purpose

- To visualize the internal esophagus, stomach, and duodenum
- To obtain a cytologic specimen.
- To confirm the presence of gastrointestinal pathology.

Procedure

- A consent form should be signed.
- The patient should be NPO for 8–12 hours before the test. When this procedure is used during an emergency and NPO cannot be enforced, the patient's stomach is lavaged (suctioned) to prevent aspiration.
- The patient may take prescribed medications at 6 a.m. on the day of the test. Check with laboratory or healthcare provider for any changes.
- A sedative/tranquilizer, a narcotic analgesic, and atropine may be given an hour before the test, or they can be titrated intravenously immediately prior to the procedure and during the procedure as needed.
- A local anesthetic may be used.
- Dentures, jewelry, and clothing should be removed from the neck to the waist.
- Record baseline vital signs. The patient should void before the procedure.

- Specimen containers should be labeled with the patient's name, the date, and the type of tissue.
- Emergency drugs and equipment should be available for hypersensitivity to medications (premedications and anesthetic) and for severe laryngospasms.
- The test takes approximately 1 hour or less.
- The patient should not drive self home following the test because of possible aftereffects of sedation.

Factors Affecting Diagnostic Results

- Barium from a recent gastrointestinal imaging series can decrease visualization of the mucosa. This test should not be performed within 2 days after such tests. An x-ray film of the abdomen can be taken to see if barium is in the stomach or duodenum.

Estrogen (Serum)

Reference Values

Adult: *Female:* Early menstrual cycle: 60–200 pg/mL. Mid-menstrual cycle: 120–440 pg/mL. Late menstrual cycle: 150–350 pg/mL. Postmenopausal: Less than 30 pg/mL. *Male:* 40–115 pg/mL.

Child: *1–6 Years:* 3–10 pg/mL. *8–12 Years:* Less than 30 pg/mL.

Description

Estrogens are produced by the ovaries, adrenal cortex, and testes. More than 30 estrogens have been identified in the

body, but only three types are measurable: estrone (E_1), estradiol (E_2), and estriol (E_3). Total serum estrogen reflects estrone, mostly estradiol, and some estriol. For fetal well-being during pregnancy, serum E_3 is used.

Purpose

- To diagnose ovarian dysfunction and other health problems.

Ferritin (Serum)

Reference Values

Adult: *Male*: 15–445 ng/mL, 15–445 mcg/L (SI units). *Female*: 10–235 ng/mL, 10–235 mcg/L (SI units). *Postmenopausal*: 10–310 ng/mL.

Child: *Newborn*: 20–200 ng/mL. *Infant (1 Month)*: 200–550 ng/mL. *Infant (2–12 Months)*: 30–200 ng/mL. *Child (1–16 Years)*: 8–140 ng/mL.

Description

Ferritin, an iron-storage protein, is produced in the liver, spleen, and bone marrow. The ferritin levels are related to the amount of iron stored in the body tissues. It will release iron from tissue reserve as needed and will store excess iron to prevent damage effects from iron overload. One nanogram per milliliter of serum ferritin corresponds to 8 mg of stored iron.

Serum ferritin is not affected by hemolysis and drugs.

Purpose

- To evaluate the amount of iron stored in the body.
- To detect early iron-deficiency anemia and anemias due to chronic disease that resemble iron deficiency.

Fetal Nonstress Test (NST) and Contraction Stress Test (CST)

Description

The fetal nonstress test (NST) and the contraction stress test (CST) are two diagnostic tests used to help evaluate fetal functioning and well-being in response to either fetal movement (NST) or to spontaneous or induced uterine contraction (CST). The NST is inexpensive, rapidly accomplished, and lacks side effects. It is helpful in identifying at-risk fetuses of mothers who exhibit high-risk pregnancy conditions, including diabetes, intrauterine growth retardation, pregnancy-induced hypertension, and report by mother of decreased fetal movements. Only minimal equipment is required (external transducer for fetal heart rate monitoring); testing occurs 1–2 times per week depending on the reason for doing the testing. The CST is also employed at 32–34 weeks in evaluating high-risk pregnancies, particularly pregnancy conditions that may place the fetus at risk if there is poor placental perfusion, including diabetes, intrauterine growth retardation, and postterm gestation over 42 weeks. In addition, certain fetuses who exhibit a nonreactive NST in the presence of additional data may also have a CST performed. Contraindications to CST testing include presence of a classical uterine incision, presence of placenta

previa, multiple gestation, and vaginal bleeding. Equipment required for CSTs includes an external transducer (for fetal heart rate [FHR] monitoring), together with a tocodynamometer (toco) for monitoring uterine contractions. The NST and CST can be performed in hospital, office, and clinical settings; the NST may also be conducted in a home care setting with supervision.

Fetal Nonstress Test (NST)

NST is a noninvasive test that monitors FHR with fetal movement. According to the American College of Obstetricians and Gynecologists, the FHR should increase by 15 bpm within a 20-minute interval. If there is no fetal movement or increased FHR in 20 minutes, the mother's abdomen may be rubbed or a loud noise made close to the abdomen to stimulate fetal movement. If after 40 minutes there is no acceleration of FHR, the NST is nonreactive and a CST may be ordered. With a nonreactive NST after 40 minutes, fetal distress may be considered; however, the fetus may be in a sleep cycle or the mother may have taken a CNS depressant drug. The NST is usually performed at 30 weeks' gestation to allow for sufficient CNS maturation, after which heart rate accelerations in response to movement become more fully established.

Contraction Stress Test (CST)

The two types of CST are the nipple stimulation test and the oxytocin challenge test (OCT). The nipple stimulation test is a noninvasive test that stimulates the hypothalamus, which promotes the release of oxytocin. This can cause uterine contractions, and a normal result would be that the FHR does not show late deceleration. The OCT is somewhat noninvasive but could induce labor in some patients. Oxytocin, a

Nursing Implications with Rationale

Fetal Nonstress Test and Contraction Stress Test

- Obtain a gestation history from the patient.
- Determine patient's knowledge level related to high-risk pregnancy condition and purposes of NST/CST testing and what these measure.
- Incorporate family into discussion and testing process as much as possible and desired.
- Remain with the patient during testing as often as possible if other supports are lacking.
- Attempt to schedule testing times at patient's convenience; follow up on missed appointments.
- Position patient correctly to prevent hypotension.
- Monitor blood pressure and other vital signs at stated intervals consistent with agency protocols.
- Report abnormal changes.

Patient Teaching

- Use testing opportunity (NST) to teach importance of observing fetal movement.
- Encourage the patient to rest following the test procedure.
- Inform the patient to report bleeding, continuous contractions, and lack of fetal movement.

B-38 Appendix B Diagnostic Values and Laboratory Tests

uterine stimulant, is well diluted in IV fluids and thus does not cause continuous contractions. Three moderate contractions should occur within 10 minutes, and the FHR should not show any late deceleration. If there is a late deceleration of FHR with contractions, the test indicates that hypoxia may result during labor due to insufficient placental function. The CST with oxytocin is performed at 32 weeks, preferably 34 weeks of gestation, which, in the event this test induces labor, would provide the fetus with a better chance of survival.

Purpose

- To evaluate fetal functioning and well-being.
- To evaluate sufficiency of uteroplacental function to support the fetus in labor.
- To screen high-risk pregnancies.

Procedure

- A signed consent form is required.
- Baseline vital signs are taken for future comparison.
- Position mother in semi-Fowler or lateral position with roll/wedge under right hip to displace uterus to the left slightly.
- Apply transducer (NST) or transducer and toco (CST).
- Monitor maternal blood pressure during the procedure for occurrence of hypotension.

Nonstress Test (NST)

- The patient presses the pressure transducer when she feels the body move.
- Monitor for FHR acceleration. There should be a 15-bpm acceleration that lasts for 15 seconds. If the FHR does not increase, rub the mother's abdomen or thump/hit a pan that is close to her abdomen to stimulate fetal movement. If there is no fetal movement in 40 minutes and no acceleration in FHR, the test indicates a nonreactive fetus.

Contraction Stress Test (CST)

Nipple Stimulation:

- The patient stimulates one nipple with water-soluble ointment until a contraction occurs. Contraction should occur within 2 minutes, and if it does not, nipple stimulation could continue for 15 minutes.
- If no late deceleration occurs during three contractions in FHR, the test result is considered normal. If late decelerations occur during any contractions, the appropriate healthcare provider should be notified, because this result can indicate that the fetus is receiving insufficient blood supply from the placenta.

Oxytocin Challenge Test (OCT)

- Vital signs and FHR are taken at frequent intervals.
- NPO may be suggested in case labor begins.
- Administer oxytocin by IV infusion pump; dosage will be ordered. The oxytocin rate may be slowly increased until the patient has a moderate contraction. If contraction occurs before the oxytocin infusion, withhold the drug.
- A normal test result is no late deceleration of FHR. A late deceleration can indicate placental dysfunction, which could cause the fetus to receive insufficient oxygen during labor.

- Test should be conducted in a health facility.
- Monitor FHR for 30–60 minutes after oxytocin infusion has been stopped.
- Test takes approximately 1–2 hours.

Factors Affecting Diagnostic Results

- NST is often nonreactive before 30–32 weeks due to central nervous system immaturity.
- NST may be classified as falsely nonreactive because of the occurrence of fetal sleep cycles.
- NST may be more commonly classified as falsely reactive in patients with diabetes and those with postterm pregnancies or pregnancy-induced hypertension associated with intrauterine growth retardation.
- NST may be falsely nonreactive when smoking has occurred prior to the NST; also in the event the patient has used CNS depressant drugs or beta-blockers.
- NST and CST equipment difficulties and/or inexperienced operators may result in difficulty obtaining or accurately interpreting tracings.

Fluoroscopy

Normal Findings

Normal size, structure, and physiologic function of the organ(s) being examined.

Description

Usually the patient is between the x-ray tube and the fluorescent screen. The x-ray beam penetrates the patient and then strikes the screen. Unfortunately, the patient can receive substantially more radiation than he or she would receive from standard radiography. Today fluoroscopy is used with many diagnostic tests for visualization and for guidance.

During cardiac catheterization, the fluoroscopic procedure is essential for visualizing the coronary arteries. The moving images can be recorded on video and can be a valuable aid to diagnosis.

During fluoroscopic examination, the room is darkened for contrast and visualization purposes. If the radiologist and assistant remain in the room, they should wear protective aprons.

Purpose

- To view the functions of organs in motion on a fluorescent screen.

Folic Acid (Folate) (Serum)

Reference Values

Adult: 3–16 ng/mL (bioassay), greater than 2.5 ng/mL (radioimmunoassay [RIA] serum), 200–700 ng/mL (red blood cells [RBCs]).

Child: Same as adult.

Description

Folic acid, one of the B vitamins, is needed for normal red and white blood cell function. Folic acid is present in a variety of foods: milk, eggs, leafy vegetables, beans, liver, fruits

(oranges, bananas), and whole-wheat bread. Dietary deficiency is the most common cause of a serum folic acid deficit, especially in children, older adults, and individuals with chronic alcoholism. With a decreased folic acid intake, folic acid deficiency develops in approximately 3–4 weeks and folic anemia occurs in 18–24 weeks.

Purpose

- To check for folic acid deficiency during early pregnancy.
- To detect folic acid anemia.

Follicle-Stimulating Hormone (FSH) (Serum and Urine)

Reference Values

Serum: *Adult: Female:* Follicular phase: 4–30 milliunit/mL. Midcycle: 10–90 milliunit/mL. Luteal phase: 4–30 milliunit/mL. Menopause: 40–170 milliunit/mL. *Male:* 4–25 milliunit/mL. *Child (Prepubertal):* 5–12 milliunit/mL.

Urine: *Adult: Female:* Follicular phase: 2–15 international unit/24 h. Midcycle: 8–60 international unit/24 h. Luteal phase: 4–20 international unit/24 h. Menopause: 50–150 international unit/24 h. *Male:* 4–18 international unit/24 h. *Child (Prepubertal):* Less than 10 international unit/mL.

Description

Follicle-stimulating hormone (FSH), a gonadotropic hormone produced and controlled by the pituitary gland, stimulates the growth and maturation of the ovarian follicle to produce estrogen in females and to promote spermatogenesis in males. Increased and decreased FSH levels can indicate gonad failure due to pituitary dysfunction.

Purpose

- To check for an FSH-producing pituitary tumor.
- To compare serum and urine FSH levels for determining the cause of infertility.

Galactose-1-Phosphate Uridyl Transferase (GPT or GPUT) (Blood)

Reference Values

Negative: Quantitative test: 18.5–28.5 unit/g in hemoglobin (Hb).

Deficiency of the Enzyme: less than 5 unit/g in Hb.
Carrier of the deficiency: 5–18 unit/g of Hb.

Description

The enzyme galactose-1-phosphate uridyl transferase (GPT) is needed to convert galactose to glucose during lactose metabolism. The enzyme deficiency is inherited or can be an acquired disorder that can occur during intrauterine development. If inherited, it is an autosomal recessive transmitted disorder. A deficiency of this enzyme can lead to galactosemia (increase in galactose in the blood due to the inability to metabolize galactose). Screening tests to detect the enzyme deficiency are performed at birth in some institutions. If the deficiency exists and is not treated soon after

birth, this condition can cause mental retardation, failure to thrive, severe liver disorder, and/or irreversible cataracts due to the lack of brain, liver, or eye development.

Purpose

- To detect galactosemia in infants and carriers of the GPT enzyme deficiency.

Gamma-Glutamyl Transferase (GGT) (Serum)

Gamma-Glutamyl Transpeptidase (GGTP, or GTP; γ -Glutamyl Transpeptidase, γ GT)

Reference Values 0–45 unit/L (Overall Average)

Adult: *Male:* 4–23 international unit/L, 9–69 unit/L at 37°C (SI units). *Female:* 3–13 international unit/L, 4–33 unit/L at 37°C (SI units). Values differ among institutions and method used.

Child: *Newborn:* 5 times higher than adult. *Premature:* 10 times higher than adult. *Child:* Similar to adult.

Older Adult: Slightly higher than adult.

Description

The enzyme gamma-glutamyl transferase (GGT) is found primarily in the liver and kidney, with smaller amounts in the spleen, prostate gland, and heart muscle. GGTP is sensitive for detecting a wide variety of hepatic (liver) parenchymal diseases. The serum level will rise early and will remain elevated as long as cellular damage persists.

High levels of GGT occur after 12–24 hours of heavy alcoholic drinking and may remain increased for 2–3 weeks after alcohol intake stops. Some alcoholic rehabilitation programs are using the GGTP level as a guide to planning care as they work with the individuals with alcoholism.

The GGT test is considered more sensitive for liver dysfunction than the alkaline phosphatase (ALP) test.

Purpose

- To detect the presence of a hepatic disorder.
- To monitor the liver enzyme GCT during the liver disorder and treatment.
- To compare with other liver enzymes to identify liver dysfunction.

Gastrointestinal (GI) Series, Upper GI Series, Barium Swallow, Small-Bowel Series, Hypotonic Duodenography

Normal Findings

Normal structure of the esophagus, stomach, and small intestine, and normal peristalsis.

Description

Upper gastrointestinal (GI) and small-bowel series are fluoroscopic and x-ray examinations of the esophagus, stomach, and small intestine. Oral barium meal (barium sulfate) or a

Nursing Implications with Rationale

Gastrointestinal Series

- Record vital signs. Note in the chart of any epigastric pain or discomfort.

Patient Teaching

- Explain the procedure to the patient concerning diet and medication restrictions; no smoking; the length of time required to complete the procedure; and the posttest laxative, if ordered (*see Procedure*).
- Inform the patient that all of the chalk-flavored liquid must be swallowed. Tell the patient the tests should not cause pain or any significant discomfort.
- Encourage the patient to ask questions or to express any concerns. Refer questions you cannot answer to other appropriate healthcare professionals.

Posttest

- Check with the radiology department that the upper GI series and/or small-bowel studies are completed before giving the late breakfast or late lunch. Usually the x-ray department will send a slip with the patient stating that the test is finished or that a 24-hour x-ray film will be needed.
- Administer the ordered laxative (e.g., milk of magnesia) after the test.

Patient Teaching

- Inform the patient that the stools should be light in color for the next several days. Instruct the patient to notify the healthcare provider if he or she does not have a bowel movement in 2–3 days. Barium can cause fecal impaction.

water-soluble contrast agent (meglumine diatrizoate [Gastrografin]) is swallowed. By means of fluoroscopy, the barium is observed as it passes through the digestive tract, and spot films are taken. Inflammation, ulcerations, and tumors of the stomach and duodenum can be detected through this procedure.

Upper GI series are performed in hospitals or in private laboratories. A preparation sheet is given or sent to the patient prior to the test.

If increased peristalsis, a spastic duodenal bulb, or a space-occupying lesion is observed or suspected in the duodenal area during the GI series, a *hypotonic duodenography* procedure can be performed by giving glucagon, atropine, or propantheline (Pro-Banthine) to slow down the action of the small intestine. Preparations for the hypotonic duodenography are similar to those for the upper GI series. Because of the anticholinergic effect of the drug, the patient should be observed closely for urinary retention.

Purposes

- To detect an esophageal, gastric, or duodenal ulcer.
- To identify polyps, tumor, or hiatal hernia in the GI tract.
- To detect foreign bodies, esophageal varices, or esophageal or small-bowel strictures.

Procedure

- The patient should be NPO (food and fluids) and should refrain from smoking for 8–12 hours before the test. A

low-residue diet may be ordered for 2 or 3 days before the test.

- Withhold medications 8 hours before the test unless otherwise indicated. Narcotics and anticholinergic drugs are withheld for 24 hours to avoid intestinal immobility.
- Laxatives may be ordered the evening before the test.
- The patient swallows a chalk-flavored (chocolate, strawberry) barium meal or meglumine diatrizoate (Gastrografin) in the calculated amount (16–20 oz).
- Spot films are taken during the fluoroscopic examination. The procedure takes approximately 1–2 hours but could take 4–6 hours if the test is to include the bowel series. A 24-hour x-ray film (post-GI series) may be requested.
- A laxative is usually ordered after the completion of the test to get the barium out of the GI tract.

Factors Affecting Diagnostic Results

- Barium in the GI tract from a recent barium study.
- Retention of foods and liquids, which would decrease visualization.
- Excessive air in the stomach and small intestine.

Glucose—Fasting Blood Sugar (FBS) (Blood)

Reference Values

Adult: *Serum and Plasma*: 70–110 mg/dL; 3.9–6.1 mmol/L (SI units).

Whole Blood: 60–100 mg/dL; 3.3–5.5 mmol/L (SI units).
Prediabetes: 100–125 mg/dL.

Panic Value: Less than 40 mg/dL; less than 2.2 mmol/L (SI units). Greater than 700 mg/dL; greater than 38.5 mmol/L (SI units).

Gestational Diabetes: Greater than 140 mg/dL; greater than 7.9 mmol/L (SI units).

Newborn: 30–80 mg/dL; 1.7–4.4 mmol/L (SI units).

Child: 60–100 mg/dL; 3.3–5.5 mmol/L (SI units).

Older Adult: *Serum*: 70–120 mg/dL; 3.9–6.7 mmol/L (SI units).

Description

Glucose is formed from dietary carbohydrates and is stored as glycogen in the liver and skeletal muscles. Insulin and glucagon, two hormones from the pancreas, affect the blood glucose level. Insulin is needed for cellular membrane permeability to glucose and for transportation of glucose into the cells. Without insulin, glucose cannot enter the cells. Glucagon stimulates glycogenolysis (conversion of stored glycogen to glucose) in the liver.

A decreased blood sugar level (hypoglycemia) results from inadequate food intake or too much insulin. When elevated blood sugar (hyperglycemia) occurs, there is not enough insulin; this condition is known as diabetes mellitus. A fasting blood sugar level greater than 125 mg/dL usually indicates diabetes, and to confirm the diagnosis when the blood sugar is borderline or slightly elevated, a fasting (postprandial) blood sugar and/or a glucose tolerance test may be ordered.

Purpose

- To confirm a diagnosis of prediabetic state or diabetic mellitus.
- To monitor blood glucose levels for diabetic patients taking an antidiabetic agent.

Glucose—Postprandial (Fasting Blood Sugar) (Blood)

Two-Hour Postprandial Blood Sugar (PPBS)

Reference Values

Adult: *Serum and Plasma*: Less than 140 mg/dL/2 h; less than 7.8 mmol/L (SI units).

Whole Blood: Less than 120 mg/dL/2 h; less than 6.7 mmol/L (SI units).

Older Adult: *Serum*: Less than 160 mg/dL/2 h; less than 8.9 mmol/L (SI units).

Whole Blood: Less than 140 mg/dL/2 h; less than 7.8 mmol/L (SI units).

Child: *Serum*: Less than 120 mg/dL/2 h; less than 6.7 mmol/L (SI units).

Description

A 2-hour PPBS or fasting sugar test is usually done to determine the patient's response to a high carbohydrate intake 2 hours after a meal (breakfast or lunch). This test is a screening test for diabetes, normally ordered if the fasting blood sugar was high normal or slightly elevated. A serum glucose greater than 140 mg/dL or a blood glucose greater than 120 mg/dL is abnormal, and further tests may be needed.

Purpose

- See Glucose—Fasting Blood Sugar.

Glucose Tolerance Test—Oral (OGTT) (Serum) and IV (IV-GTT)

Reference Values

Adult:

Oral GTT Time	Serum	
	(mg/dL)	(mmol/L)
Fasting	70–110	3.9–6.1
0.5 hour	<160	<8.9
1 hour	<170	<9.4
2 hours	<125	<6.9
3 hours	Fasting levels	

Oral GTT Time	Blood	
	(mg/dL)	(mmol/L)
Fasting	60–100	3.3–5.5
0.5 hour	<150	<8.3
1 hour	<160	<8.9
2 hours	<115	<6.9
3 hours	Fasting levels	

IV Glucose Tolerance Test		
Time	Serum	
	(mg/dL)	(mmol/L)
Fasting	70–110	3.9–6.1
5 minutes	<250	<13.8
0.5 hour	<155	<8.5
1 hour	<125	<6.9

Child: Depends on the child's age. Infants normally have lower blood sugar levels (see *Glucose—Fasting Blood Sugar*). A child age 6 or older has results similar to those of an adult.

Description

A glucose tolerance test (GTT) may be indicated when there is a familial history of diabetes, in women having babies weighing 10 lb or more, in individuals having extensive surgery or injury, and in those with obesity problems. The test should *not* be performed if the fasting blood sugar (FBS) is greater than 200 mg/dL. After the age of 60 years, the blood glucose level is usually 10–30 mg/dL higher than the "normal range."

The peak glucose level for the oral GTT (OGTT) is 0.5–1 hour after the ingestion of 100 g of glucose, and the blood sugar should return to normal range in 3 hours. Blood samples will be collected at specified times.

The *intravenous glucose tolerance test (IV-GTT)* is considered by many to be more sensitive than the oral GTT, because absorption through the gastrointestinal tract is not involved. The IV-GTT is usually done if an individual cannot eat or tolerate oral glucose. The blood glucose returns to the normal range in 2 hours. However, the values for the OGTT and IV-GTT slightly differ, because IV glucose is absorbed faster.

Hyperinsulinism can be detected with the OGTT. After 1 hour the blood glucose level is usually lower than in the FBS test. The person might develop severe hypoglycemic reactions (i.e., more insulin is being secreted in response to the blood glucose).

Purpose

- To confirm the diagnosis of diabetes mellitus in individuals having high-normal or slightly elevated blood sugar values.

Growth Hormone (GH), Human Growth Hormone (hGH) (Serum)

Somatotropic Hormone (STH)

Reference Values

Adult: *Male*: Less than 5 ng/mL. *Female*: Less than 10 ng/mL.

Child: Less than 10 ng/mL.

Description

Human growth hormone (hGH), hormone from the anterior pituitary gland, regulates growth of bone and tissue. Growth

hormone levels are elevated by protein food, fasting, stress, exercise, and deep sleep.

A low serum hGH level might be the cause of dwarfism. Elevated hGH levels cause gigantism in children and acromegaly in adults. From a random growth hormone level, a positive diagnosis cannot be made; therefore a *growth hormone stimulation or suppression challenge test* would be suggested. A glucose-loading GH suppression test should suppress hGH secretion. Failure to suppress hGH levels confirms gigantism (children) or acromegaly (adults).

Purpose

- To determine the presence of human growth deficit or excess.
- To aid in the diagnosis of dwarfism, gigantism, or acromegaly.

Hematocrit (Hct) (Blood)

Reference Values

Adult: *Male*: 40–54%, 0.40–0.54 (SI units). *Female*: 36–46%, 0.36–0.46 (SI units). *Panic Value*: Less than 15% and greater than 60%.

Child: *Newborn*: 44–65%. *1–3 Years Old*: 29–40%. *4–10 Years Old*: 31–43%.

Description

The hematocrit (Hct) is the volume (in milliliters) of packed red blood cells (RBCs) found in 100 mL (1 dL) of blood, expressed as a percentage. For example, a 36% hematocrit would indicate that 36 mL of RBCs was found in 100 mL of blood, or 36 vol/dL.

Low hematocrits are found frequently in anemias and leukemias, and elevated levels are found in dehydration (a relative increase) and polycythemia vera. The hematocrit can be an indicator of the hydration status of the patient. As with hemoglobin, an elevated hematocrit could indicate hemoconcentration because of a decrease in fluid volume and an increase in RBCs.

Purpose

- To monitor the volume of RBCs (erythrocytes) in the blood.

Factors Affecting Laboratory Results

- If blood is collected from an extremity that has an IV line, the hematocrit will most likely be low. Avoid using such an extremity.
- If blood is taken to check the hematocrit immediately after moderate to severe blood loss and transfusions, the hematocrit could be normal.
- Age of the patient; for example, newborns normally have higher hematocrits because of hemoconcentration.

Hemoglobin (HB or HGB) (Blood)

Reference Values

Adult: *Male*: 13.5–18 g/dL; 8.4–11.2 mmol/L (SI units). *Female*: 12–15 g/dL; 7.45–9.31 mmol/L (SI units).

Child: *Newborn*: 14–24 g/dL. *Infant*: 10–17 g/dL. *Child*: 11–16 g/dL.

Description

Hemoglobin (Hb or Hgb), a protein substance found in red blood cells (RBCs), gives blood its red color. Hemoglobin is composed of iron, which is an oxygen carrier. Abnormally high hemoglobin levels may be due to hemoconcentration resulting from dehydration (fluid loss). Low hemoglobin values are related to various clinical problems.

The RBC count and hemoglobin level do not always increase or decrease equally. For instance, a decreased RBC count and a normal or slightly decreased hemoglobin level occur in pernicious anemia, and a normal or slightly decreased RBC and a decreased hemoglobin level occur in iron deficiency (microcytic) anemia.

Purpose

- To monitor the hemoglobin value in RBCs.
- To assist in diagnosing anemia.
- To suggest the presence of body fluid deficit due to an increased hemoglobin level.

Factors Affecting Laboratory Results

- Drugs could increase or decrease hemoglobin.
- Taking blood from an arm or hand receiving IV fluids could dilute the blood sample.
- Leaving the tourniquet on for more than a minute will cause hemostasis, which will result in a falsely elevated hemoglobin level.
- Living at high altitudes will increase hemoglobin levels.
- Decreased fluid intake or fluid loss will increase hemoglobin levels due to hemoconcentration, and excessive fluid intake will decrease hemoglobin levels due to hemodilution.

Hemoglobin A_{1c} (Hgb A_{1c} or Hb A_{1c}) (Blood)

Glycosylated Hemoglobin (Hgb A_{1a}, Hgb A_{1b}, Hgb A_{1c}, Glycohemoglobin)

Reference Values

Total Glycosylated Hemoglobin: 5.59% of total Hgb (Hb).

Adult: *Hgb (Hb) A_{1c}*: Nondiabetic: 2–5%. Diabetic Control: 2.5–6%; high average; 6.1–7.5%. Diabetic Uncontrolled: Greater than 8%.

Child: *Hgb (Hb) A_{1c}*: Nondiabetic: 1.5–4%.

Description

Hemoglobin A (Hgb or Hb A) makes up 91–95% of total hemoglobin. A glucose molecule is attached to Hb A₁, which is a portion of hemoglobin A. This process of attachment is called *glycosylation* and produces *glycosylated hemoglobin* or *hemoglobin A₁*. There is a bond between glucose and hemoglobin. Formation of Hb A₁ occurs slowly over 120 days, the lifespan of red blood cells (RBCs). Hb A₁ is composed of three hemoglobin molecules, Hb A_{1a}, Hb A_{1b}, and Hb A_{1c}, of which 70% Hb A_{1c} is 70% glycosylated (absorbs glucose). The amount of glycosylated hemoglobin depends on the amount of blood glucose available. When the blood glucose

level is elevated over a prolonged period of time, the red blood cells (RBCs) become saturated with glucose; glycohemoglobin results.

A glycosylated hemoglobin represents an average blood glucose level during a 1- to 3-month period. Fasting blood sugar reflects the blood glucose level at a one-time fasting state, whereas the Hgb or Hb A_{1c} is a better indicator of diabetes mellitus control. However, a false decreased Hb A_{1c} level can be caused by a decrease in RBCs.

An elevated Hb A_{1c} greater than 8% indicates uncontrolled diabetes mellitus, and the patient is at a high risk of developing long-term complications, such as nephropathy, retinopathy, neuropathy, and/or cardiopathy. Total glycohemoglobin may be a better indicator of diabetes control for patients with anemias or blood loss.

Purpose

- To monitor the effectiveness of diabetes therapy.
- To provide information regarding the presence of diabetes mellitus.

Factors Affecting Laboratory Results

- Anemias may cause a low value result.
- Hemolysis of the blood specimen can cause an inaccurate test result.
- Heparin therapy may cause a false test result.

Holter Monitoring, Ambulatory Electrocardiography, Dynamic Electrocardiography

Normal Findings

No abnormal electrocardiographic findings.

Description

Holter monitoring (ambulatory electrocardiography) evaluates the patient's heart rate and rhythm during normal daily activities, rest, and sleep over 24 hours (occasionally 48 hours). The Holter monitor is a device the size of a small camera that provides a continuous electrocardiogram (ECG) recording. After 24 hours, the monitor with the recording is returned to the cardiac center and is scanned or reviewed for abnormal findings such as cardiac dysrhythmias.

The Holter recorder contains a clock that is coordinated with the tape recorder and an event marker for the patient to use when having symptom(s). The patient is given a diary to record the symptoms such as palpitations, chest pain, shortness of breath, syncope, vertigo, and the time of the symptoms.

Holter monitoring is more sensitive than a routine ECG for identifying the cause of symptoms.

Purpose

- To identify cardiac dysrhythmias related to cardiac symptoms as marked on the monitor and recorded in the diary.

Procedure

- A signed consent form may be required.
- Food and fluids are not restricted.

- The skin is cleansed and shaved as needed, and electrodes are placed over bony areas to eliminate artifacts that could be caused by skeletal muscle movements.
- Five to seven electrode patches are placed on the chest. For a five-lead electrode placement, two negative electrodes are secured at the upper right and left manubrial border of the sternum, and two positive electrodes are placed below the sternum, one placed 2 cm to the right of the xiphoid process on the rib margin and the second at the left anterior axillary line—sixth rib. A ground electrode is secured at the lower right rib margin over the bone.
- The patient is given a diary to record what he or she was doing when symptom(s) such as palpitations, chest pain, and shortness of breath occurred.
- The patient should not shower, take a bath, or swim until the electrodes have been removed. The patient should also avoid vigorous exercise and sweating.

Posttest

- The patient returns the Holter monitor the next day (24 hours later) with the diary.
- The nurse/technician reviews the diary with the patient for any needed clarification.
- The tape is scanned (reviewed) and the cardiologist submits a written report to the patient's healthcare provider, who will then explain the ECG monitoring results to the patient.

Human Chorionic Gonadotropin (HCG) (Serum and Urine), Pregnancy Test

Reference Values

Values may be expressed as international unit/mL or ng/mL. Check with your laboratory.

Adult: *Serum*: Nonpregnant woman: Less than 0.01 international unit/mL.

Pregnant (Weeks)	Values (International Unit/mL)
1	0.01–0.04
2	0.03–0.10
4	0.10–1.0
5–12	10–100
13–25	10–30
26–40	5–15

Urine: Nonpregnant: Negative. Pregnant (1–12 Weeks): 6000–500,000 international unit/24 h. Many OTC pregnancy kits are available. The woman is usually tested 5–14 days after a missed menstrual period.

Description

Human chorionic gonadotropin (HCG) is a hormone produced by the placenta. In pregnancy, HCG appears in the blood and urine 14–26 days after conception, and the HCG concentration peaks in approximately 8 weeks. After the

B-44 Appendix B Diagnostic Values and Laboratory Tests

first trimester of pregnancy, HCG production declines. HCG is not found in nonpregnant women, in death of the fetus, or after 3–4 days postpartum.

Certain tumors (such as the hydatidiform mole, chorion-epithelioma of the uterus, and choriocarcinoma of the testicle) can cause a positive HCG test. HCG levels may be requested on males for the determination of testicular tumor.

Purpose

- To determine if the patient is pregnant.
- To detect threatened abortion or dead fetus.

Procedure

- There is no food restriction.
- Perform the pregnancy test 2 weeks (no earlier than 5 days) after the first missed menstrual period. Several commercially prepared immunologic pregnancy test kits are available.

Serum

- Perform the pregnancy test no earlier than 5 days after the first missed menstrual period.
- Collect 3–5 mL of venous blood in a red-top tube. Avoid hemolysis.

Urine

- The patient should be NPO of fluid for 8–12 hours; no food is restricted.
- Take a morning urine specimen (60 mL) with specific gravity greater than 1.010 to the laboratory immediately. A 24-hour urine collection may be requested.
- Instruct the patient to follow directions when using a commercial kit.
- Avoid blood in the urine, because false-positive results could occur.

Note: There are many commercial kits; follow the directions on the kit.

Factors Affecting Laboratory Results

- Diluted urine (specific gravity less than 1.010) could cause a false-negative test result.
- Certain drug groups can cause false-positive test results.
- Protein and blood in the urine could cause false-positive test results.
- During menopause, women may experience an excess secretion of pituitary gonadotropin hormone, which could cause a false-positive result.

Human Immunodeficiency Virus Type 1 (HIV-1) or HIV* (Serum)

Reference Values

Antibody Screening: *Adult and Child:* Negative for antibodies, Enzyme-linked Immunosorbent Assay (ELISA)

Antigen Screening: *Adult and Child:* Negative for p24 antigen, Polymerase Chain Reactions (PCR), bDNA

Description

HIV is the retrovirus that causes acquired immunodeficiency syndrome (AIDS). Retroviruses are composed of RNA instead of DNA. The predominant “host cell” for HIV is the CD4+T lymphocyte. The rate of HIV replication in infected individuals is estimated at greater than a billion per day. The primary HIV syndrome’s onset of symptoms begins 2–4 weeks after exposure in 80–90% of patients. These include fever (96%), adenopathy (74%), pharyngitis (70%), rash (70%), and mouth ulcers (70%). Seroconversion occurs in 3 weeks, but may take up to 3–6 months to produce enough detectable antibodies.

Purpose

- To screen for the presence of HIV infection.
- To monitor HIV during drug therapy.

Immunoglobulins (Ig) (Serum), IgG, IgA, IGM, IGD, IGE

Reference Values

	Total Ig (99% mg/dL)	IgG (80% mg/DL)	IgA (15% mg/dL)
Adult	900–2200	650–1700	70–400
6–16 years	800–1700	700–1650	80–230
4–6 years	700–1700	550–1500	50–175
1–3 years	400–1500	300–1400	20–150
6 months	225–1200	200–1100	10–90
3 months	325–750	275–750	5–55
Newborn	650–1450	700–1480	0–12

	IgM (4% mg/dL)	IgD (0.2% mg/dL)	IgE (0.0002% U/mL)
Adult	40–350	0–8	<40
(IgE 0–120 mg/dL)			
6–16 years	80–230	45–260	<62
4–6 years	22–100		<25
1–3 years	40–230		<10
6 months	10–80		
3 months	15–70		
Newborn	5–30		

Description

The five classes of immunoglobulins—IgG, IgA, IgM, IgD, and IgE—are known as antibodies. They are produced by B lymphocytes and plasma cells and respond to invading foreign antigens. When the individual is exposed to the same antigen, immunity results.

Purpose

- To identify the occurrence of total or a specific elevated immunoglobulin.
- To associate a specific immunoglobulin elevation with a health problem.

Insulin (Serum), Insulin Antibody

Reference Values

Adult: *Serum Insulin*: 5–25 microunit/mL, 42–156 pmol/L (SI units). *Panic Value*: 7 unit/mL, 7 microunit/mL (SI units).

Insulin Antibody Test: No insulin antibodies present.

Description

Insulin, a hormone from the beta cells of the pancreas, is essential in transporting glucose to the cells for metabolism. Increased glucose levels stimulate insulin secretion.

Serum insulin and blood glucose levels are compared to determine the glucose disorder. Serum insulin is valuable in diagnosing insulinoma (islet cell tumor) and islet cell hyperplasia and in evaluating insulin production in diabetes mellitus. In insulinoma the serum insulin is high, and blood glucose is less than 30 mg/dL. Hyperinsulinemia can occur in obesity as well as in insulinoma.

The **insulin antibody test** is ordered when an individual with diabetes, taking pork or beef insulin, requires larger and larger insulin dosages. Insulin antibodies develop as the result of impurities in animal insulins. These antibodies are of immunoglobulin types (i.e., IgG [most common], IgM, and IgE). The IgG antibodies neutralize the insulin, thus preventing glucose metabolism. IgM antibodies can cause insulin resistance, and IgE could be responsible for allergic effects.

Purpose

- To check for the presence of insulin antibodies that can affect insulin absorption and dosage.

International Normalized Ratio (INR) (Plasma)

Reference Values

Oral Anticoagulant Therapy: 2.0–3.0 INR.

Higher Value for Mechanical Heart Valve: 2.5–3.5 INR.

Description

The World Health Organization (WHO) recommends the use of the international normalized ratio (INR) for a more consistent reporting of PT (prothrombin time) results. The INR is calculated by the use of a nomogram demonstrating the relationship between the INR and the prothrombin time ratio. Usually both PT and INR values are reported for monitoring warfarin (Coumadin) therapy.

Purpose

- To monitor anticoagulant therapy for patients receiving warfarin (Coumadin) therapy.

Intravenous Pyelography (IVP)

Normal Findings

Normal size, structure, and function of the kidneys, ureters, and bladder.

Description

Intravenous pyelography (IVP) is more properly called *excretory urography*, because it visualizes the entire urinary tract and not just the kidney and pelvis. A radiopaque substance (sodium diatrizoate or meglumine diatrizoate [Renografin-60]) is injected intravenously and a series of x-rays are taken at specific times. The test usually takes 30–45 minutes.

A few patients may be hypersensitive to the radiopaque iodine dye, especially if they have a history of allergy to many substances. Emergency drugs (epinephrine, vasopressors, and so on), a tracheostomy set, a suction machine, and oxygen should be available for treating anaphylactoid reaction if it should occur.

Purpose

- To identify abnormal size, shape, and functioning of the kidney.
- To detect renal calculi, tumors, or cysts.

Procedure

- A consent form for IVP should be signed by the patient or an appropriate member of the family.
- The patient should be NPO for 8–12 hours before the test. In the morning the patient may be slightly dehydrated; however, this will help the kidney to concentrate the dye.
- A laxative is ordered the night before, and a cleansing enema(s) is ordered the morning of the test. These preparations may vary, so check with the radiology department for exact preparations.
- An antihistamine or a steroid may be given prior to the test to patients who are hypersensitive to the iodine, seafood, and contrast dye used in other diagnostic tests as well as to those who have histories of asthma and severe allergies.
- Baseline vital signs should be recorded.
- The patient lies in the supine position on an x-ray table. X-rays are taken 3, 5, 10, 15, and 20 minutes after the dye is injected.
- Emergency drugs and equipment should be available at all times.
- The test takes approximately 30–45 minutes. A delay in visualizing the kidneys could indicate kidney dysfunction.
- The patient voids at the end of the test and another x-ray is taken to visualize the residual dye in the bladder.

Factors Affecting Diagnostic Results

- Feces, gas, and barium in the intestinal tract can decrease visualization of the kidney, ureters, and bladder.

Iron (Fe), Total Iron-Binding Capacity (TIBC), Transferrin, Transferrin Saturation (Serum), Iron-Binding Capacity (IBC)

Reference Values

	Serum Iron	TIBC
Adult	50–150 mcg/dL 10–27 μ mol/L (SI units) Men slightly higher	250–450 mcg/dL
Older adult	60–80 mcg/dL	<250 mcg/dL
Child		
Newborn	100–270 mcg/dL	60–175 mcg/dL
Infant		100–400 mcg/dL
6 months–2 years	40–100 mcg/dL	100–135 mcg/dL
>2 years		40–100 mcg/dL

	Serum Transferrin	Transferrin Saturation
Adult	200–430 mg/dL	30–50% (male) 20–35% (female)
Older adult		
Child		
Newborn	125–275 mg/dL	
Infant		
6 months–2 years		
>2 years		

Description

Iron (Fe) is absorbed from the duodenum and upper jejunum; the amount absorbed usually covers the amount of iron that has been lost. The average daily iron intake is 10–20 mg.

Iron is coupled with the iron-transporting protein **transferrin**. Transferrin is responsible for transporting iron to the bone marrow for the purpose of hemoglobin synthesis. The storage compound for iron is ferritin (*see Ferritin*). Serum iron levels are elevated when there is excessive red blood cell destruction (hemolysis), and levels are decreased in iron deficiency anemia.

Total iron-binding capacity (TIBC) measures the maximum amount of iron that can bind to the protein transferrin. The level of TIBC decreases with age. Usually, serum iron and TIBC are determined together.

Transferrin can be measured as serum and as a percent of saturation (transferrin saturation). The transferrin saturation is the ratio between serum iron and TIBC relating to the availability of transferrin in binding with iron. Transferrin saturation is given as a percentage.

An accompanying table gives the various tests used for diagnosing health problems related to iron and transferrin imbalances.

Nursing Implications with Rationale Intravenous Pyelography

- Obtain a patient history of known allergies. Notify the healthcare provider if the patient is allergic to seafood, iodine preparations, or contrast dye. As a precaution, an antihistamine or a steroid drug may be ordered if the patient has an allergic reaction to drugs. A skin test may be performed to determine how hypersensitive the patient is to the radiopaque contrast dye.
- Check the blood urea nitrogen (BUN) level. If BUN levels are greater than 40 mg/dL, notify the healthcare provider. Normally the test would not be done.

Patient Teaching

- Explain to the patient that the purpose of the test is to detect any kidney disorder or to observe the size, shape, and structure of the kidney, ureters, and bladder.
- Explain the procedure to the patient. As a reminder, the procedural steps could be listed for the patient.
- Instruct the patient that he is not to eat or drink after dinner. Mild dehydration usually occurs. This could be harmful to patients with poor renal output, especially older adults and those who are debilitated. Sips of water or a glass of water may be indicated to avoid complications.
- Inform the patient that he may feel a transient flushing or burning sensation and a salty or metallic taste during or following the IV injection of the contrast dye.
- Encourage the patient to ask questions and to express any concerns before and during the procedure to the nurse, radiologist, and technician.

Posttest

- Monitor vital signs and urinary output.
- Observe, report, and record possible delayed reactions to the contrast dye (e.g., dyspnea, rashes, flushing, urticaria [hives], tachycardia).
- Check the site where the dye was injected (usually it is in the antecubital fossa vein). If pain, warmth, or redness at the injection site is present, apply warm compresses, with permission.
- Administer oral antihistamines or steroids as ordered to treat dye reactions.

Serum Iron, TIBC, Transferrin, and Transferrin Saturation

Serum Iron	TIBC	Transferrin	Transferrin Saturation	Health Problems
Low	High	High	Low	Iron-deficiency anemia
Low	Low	Low	Normal	Chronic illness: cancer, infection, cirrhosis
High	Normal or low	Low	Very high	Iron therapy overload

Purpose

- To determine a probable cause of iron excess or deficit.
- To compare serum iron and TIBC for diagnosing iron-deficiency anemia.

Lactic Acid (Blood)

Reference Values

Adult: *Arterial Blood*: Less than 11.3 mg/dL, 0.5–2.0 mmol/L (SI units). *Venous Blood*: 8.1–15.3 mg/dL, 0.5–1.5 mmol/L (SI units). *Panic Range*: Greater than 45 mg/dL, greater than 5 mEq/L (SI units).

Description

Blood lactic acid or lactate is an indicator of the presence of lactic acidosis. Increased secretion of lactic acid occurs following strenuous exercise and acute or prolonged hypoxemia. A major cause of metabolic acidosis is excess circulating lactic acid. Shock and severe dehydration cause cell catabolism (cell breakdown) and an accumulation of acid metabolites, such as lactic acid.

Lactic acidosis is suspected if the anion gap is greater than 17 mEq/L and pH is decreased.

Excess lactic acid can decrease pH and cause lactic acidosis.

Purpose

- To detect the presence of acidosis related to shock, trauma, or severe illness.

Lactic (Lactate) Dehydrogenase (LD or LDH), LDH Isoenzymes (Serum)

Reference Values

Adult: *Total LDH*: 100–190 international unit/L, 70–250 unit/L. Values can differ according to the method used.

Isoenzymes: LDH₁, 14–26%; LDH₂, 27–37%; LDH₃, 13–26%; LDH₄, 8–16%; LDH₅, 6–16%. Differences of 2–4% are considered normal.

Child: *Newborn*: 300–1500 international unit/L. *Child*: 50–150 international unit/L, 110–295 unit/L.

Description

Lactic dehydrogenase (LDH) is an intracellular enzyme present in nearly all metabolizing cells, with the highest concentrations in the heart, skeletal muscle, liver, kidney, brain, and red blood cells (RBCs). LDH has two distinct subunits: M (muscle) and H (heart). These subunits are combined in different formations to make five isoenzymes:

- LDH₁: cardiac fraction; H, H, H, H; in heart, RBCs, kidneys, brain (some)
- LDH₂: cardiac fraction; H, H, H, M; in heart, RBCs, kidneys, brain (some)
- LDH₃: pulmonary fraction; H, H, M, M; in lungs and other tissues; spleen, pancreas, adrenal, thyroid, lymphatics
- LDH₄: hepatic fraction; H, M, M, M; liver, skeletal muscle, kidneys and brain (some)
- LDH₅: hepatic fraction; M, M, M, M; liver, skeletal muscle, kidneys (some).

Like other enzymatic tests, such as the creatine phosphokinase (CPK) and aspartate aminotransferase (AST) tests,

serum LDH and LDH₁ are used for diagnosing acute myocardial infarction (MI). A high serum LDH (total) level occurs 12–24 hours after the infarction, reaches its peak in 2–5 days, and remains elevated for 6–12 days, making it a useful test for delayed diagnosis of MI. A flipped LDH₁/LDH₂ ratio, with LDH₁ the highest, indicates a myocardial infarction.

LDH₃ is linked to pulmonary diseases, and LDH₅ is linked to liver and skeletal muscle diseases. In acute hepatitis, total LDH rises, and the LDH₅ usually rises before jaundice develops and falls before the bilirubin level does.

Purpose

- To aid in the diagnosis of myocardial or skeletal muscle damage.
- To compare test results with other cardiac enzyme tests.
- To check LDH isoenzyme results to determine organ involvement.

Laparoscopy

Normal Findings

Normal abdominal and pelvic organs; no pathology noted.

Description

Laparoscopy is the insertion of a laparoscope through the abdominal wall into the peritoneum. A light camera is usually attached to the scope for visualization.

Laparoscopy and **pelviscopy** are useful for diagnosing endometriosis, ovarian cyst, tubal pregnancy, uterine fibroids, benign and malignant tumors, pelvic inflammatory disease (PID), salpingitis, cause of infertility, and adhesions. Surgical procedures can be performed with laparoscopy, such as biopsy, tubal ligation, release of adhesions, and laser treatment for endometriosis.

Peritoneoscopy is primarily prescribed to view the liver and to stage cancers, including lymphomas. It can be used for surgical procedures such as cholecystectomy, appendectomy, hernia repairs including hiatal hernia, bowel resection, and biopsies. Laparoscopy and peritoneoscopy overlap somewhat with their surgical procedures. These tests are usually performed with general anesthesia.

Contraindications for a laparoscopy include advanced abdominal wall cancer, severe bleeding disorder, and severe respiratory and/or cardiac disorders.

Purpose

- To visualize the abdominal and pelvic organs.
- To perform surgical procedures within the abdominal and pelvic region.

Procedures

Pretest

- A signed consent form is required.
- The patient should be NPO after midnight or 8–12 hours prior to the test procedure.
- Anticoagulant therapy should be discontinued 5–7 days prior to the test.
- Laboratory tests are ordered prior to the test.

Nursing Implications with Rationale

Laparoscopy

- Obtain a history of the patient's health problem. Relate findings to other health professionals.
- Check baseline vital signs (VS). These VS are compared with those taken during the test procedure and during the posttest period.
- Report gas pains that remain beyond 24–36 hours and any frank bleeding from incision site.
- Follow the posttest procedure.

Patient Teaching

- Discuss the need to take analgesics as ordered to relieve pain and discomfort due to the gas that was inserted in the abdomen. Inform the patient that all the gas in the abdomen is not always released immediately after the procedure; it may take 24 hours.
- Instruct the patient to report pain that lasts for 48 hours or more and any bright bleeding that occurs at the incisional site.
- Answer the patient's questions. If unable to, refer the questions to the primary healthcare provider or other professionals.

- Cleansing enemas are performed as ordered the night before the procedure and/or in the morning.
- The patient should void before the procedure.
- An IV infusion is started. IV medications may be given through the IV line.

Test Procedure

- A small surgical incision is made below the umbilicus.
- The peritoneal cavity is filled with carbon dioxide gas so that the organs can easily be visualized.
- A laparoscope is inserted through a trocar.
- After the procedure, carbon dioxide escapes; however, not all of the gas is removed but will be slowly eliminated from the body over a period of 24 hours.

Posttest

- Vital signs are monitored and bleeding from the small incisional area is checked periodically.
- Analgesics for pain and for shoulder or subcostal discomfort caused by carbon dioxide gas may be given every 4–6 hours.
- Physical activity should be minimized for 4–7 days posttest or as instructed by the healthcare provider.

Factors Affecting Diagnostic Results

- Excessive adhesions.
- Severe obesity.

Lead (Blood)

Reference Values

Adult: *Normal:* 10–20 mcg/dL. *Acceptable:* 20–40 mcg/dL. *Excessive:* 40–80 mcg/dL. *Toxic:* 80 mcg/dL.

Child: *Normal:* 10–20 mcg/dL. *Acceptable:* 20–30 mcg/dL. *Excessive:* 30–50 mcg/dL. *Toxic:* 50 mcg/dL.

Description

Excessive lead exposure due to occupational contact is a hazard to adults; however, most industries will accept a 40 mcg/dL blood lead level as a normal value. Lead toxicity can occur in children from eating chipped, lead-based paint found in old houses. Sources of lead include leaded gasoline (fumes), lead-based paint, unglazed pottery, and “moonshine” whiskey prepared in lead containers.

Lead is usually excreted rapidly in the urine, but if excessive lead exposure persists, the lead will accumulate in the bone and soft tissues. Chronic lead poisoning is more common than acute poisoning. Lead colic (crampy abdominal pain) occurs in both acute and chronic lead poisoning.

Purpose

- To check for lead toxicity.

Lecithin/Sphingomyelin (L/S) Ratio (Amniotic Fluid)

Reference Values

Before 35 Weeks of Gestation: 1:1. *Lecithin (L):* 6–9 mg/dL. *Sphingomyelin (S):* 4–6 mg/dL.

After 35 Weeks of Gestation: 4:1. *Lecithin (L):* 15–21 mg/dL. *Sphingomyelin (S):* 4–6 mg/dL.

Description

Lecithin (L), a phospholipid, is responsible mostly for the formation of alveolar surfactant. Surfactant lubricates the alveolar lining and inhibits alveolar collapse, thus preventing atelectasis. Sphingomyelin (S) is another phospholipid, the value of which remains the same throughout pregnancy. A marked rise in amniotic lecithin after 35 weeks (to a level 3–4 times higher than that of sphingomyelin) is considered normal, and so chances for having hyaline membrane disease are small.

Purpose

- To predict neonatal respiratory distress syndrome (also called hyaline membrane disease) before delivery.
- To determine fetal maturity in the event that the gestation period is uncertain.

Procedure

- Consent form should be signed.
- Food, fluids, and medications are not restricted.
- The physician obtains amniotic fluid by the method of amniocentesis. The specimen should be cooled immediately to prevent the destruction of lecithin by certain enzymes in the amniotic fluid. The specimen should be frozen if testing cannot be done at a specified time (check with the laboratory).
- Care should be taken to prevent puncture of the mother's bladder. If urine in the specimen is suspected, then the specimen should be tested for urea and potassium. If these two levels are higher than blood levels, the

specimen could be urine and not amniotic fluid. Ultrasound is frequently used when obtaining amniotic fluid.

Factors Affecting Laboratory Results

- Maternal vaginal secretions or a bloody tap into the amniotic fluid may cause a falsely increased reading for lecithin.
- The amniotic fluid specimen should be tested immediately to prevent inaccurate results.

Lipase (Serum)

Reference Values

Adult: 20–180 international unit/L, 114–286 unit/L, 14–280 unit/L (SI units). Norms vary among laboratories.

Child: *Infant*: 9–105 international unit/L at 37°C. *Child*: 20–136 international unit/L at 37°C.

Description

Lipase, an enzyme secreted by the pancreas, aids in digesting fats. Lipase, like amylase, appears in the bloodstream following damage to the pancreas. Acute pancreatitis is the most common cause for an elevated serum lipase level. Lipase and amylase levels increase early in the disease, but serum lipase can be elevated for up to 14 days after an acute episode, whereas the serum amylase returns to normal after approximately 3 days.

Purpose

- To suggest pancreatitis or other pancreatic disorders.

Lipoproteins, Lipoprotein Electrophoresis, Lipids (Serum)

Reference Values

Adult: *Total*: 400–800 mg/dL, 4–8 g/L (SI units). *Cholesterol*: 150–240 mg/dL (see test on cholesterol). *Triglycerides*: 10–190 mg/dL (see test on triglycerides). *Phospholipids*: 150–380 mg/dL.

LDL: 60–160 mg/dL. *Risk for CHD*: High: Greater than 160 mg/dL. Moderate: 130–159 mg/dL. Low: Less than 130 mg/dL. Desirable: 100 mg/dL.

HDL: 29–77 mg/dL. *Risk for CHD*: High: Less than 35 mg/dL. Moderate: 35–45 mg/dL. Low: 46–59 mg/dL. Very low: Greater than 60 mg/dL.

Child: (See tests on cholesterol and triglycerides.)

Description

Lipoproteins are lipids bound to protein, and the three main lipoproteins are cholesterol, triglycerides, and phospholipids. The two fractions of lipoproteins—alpha (α), high-density lipoproteins (HDL), and beta (β), low-density lipoproteins (chylomicrons, VLDL, LDL)—can be separated by electrophoresis. The beta groups are the largest contributors to atherosclerosis and coronary artery disease (CAD). HDL, called “friendly lipids,” are composed of 50% protein and do aid in decreasing plaque deposits in blood vessels.

Increased lipoproteins (hyperlipidemia or hyperlipoproteinemia) can be phenotyped into five major types (I, IIA

and IIB, III, IV, V). Cholesterol and triglycerides are the two lipids in each type found in varying amounts. With type II, the cholesterol is highly elevated, and the triglycerides are slightly increased. With type IV, the triglycerides are highly elevated, and the cholesterol is slightly increased. Types II and IV are the most common phenotypes and are the most prevalent in atherosclerosis and CAD.

Lipoprotein Phenotype: Hyperlipidemia	
Type	Lipid Composition*
I	Increased chylomicrons, increased triglycerides; rare pattern of hyperlipidemia
IIA	Increased beta (low-density) lipoproteins (LDL); increased cholesterol, slightly increased triglycerides or normal; common pattern of hyperlipidemia
IIB	Increased beta and pre-beta lipoproteins, both cholesterol and triglycerides are elevated; common pattern of hyperlipidemia
III	Moderately increased cholesterol and triglycerides; uncommon pattern of hyperlipidemia
IV	Increase of pre-beta (very low-density) lipoproteins (VLDL); slightly increased cholesterol and markedly increased triglycerides; common pattern of hyperlipidemia
V	Increased chylomicrons, VLDL, and triglycerides, and slightly increased cholesterol; uncommon pattern of hyperlipidemia

*Types II and IV are increased in atherosclerosis and coronary artery diseases.

Purpose

- To identify patients with hyperlipoproteinemia.
- To distinguish between the phenotypes of lipidemias.
- To monitor lipid counts for patients with hyperlipidemia.

Lithium (Serum)

Eskalith, Lithobid, Eskalith CR, Lithotabs, Cibalith

Reference Values

Adult: *Normal*: Negative. *Therapeutic*: 0.8–1.2 mEq/L. *Toxic*: Greater than 1.5 mEq/L. *Lethal*: Greater than 4.0 mEq/L.

Child: Not usually given to children.

Description

Lithium is used to treat mania associated with bipolar disorder. Because therapeutic and toxic lithium ranges are narrow, serum lithium should be closely monitored.

Purpose

- To monitor lithium levels for therapeutic effect and toxicity.

Luteinizing Hormone (LH) (Serum and Urine)

Reference Values

Ranges vary among laboratories.

Serum: *Adult*: Female: Follicular phase: 5–30 milli-international unit/mL. Midcycle: 50–150 milli-international unit/mL. Luteal Phase: 2–25 milli-international unit/mL. *Postmenopausal*: 40–100 milli-international unit/mL.

Male: 5–25 milli-international unit/mL. *Child:* 6–12 Years: Less than 10 milli-international unit/mL. 13–18 Years: Less than 20 milli-international unit/mL.

Urine: *Adult:* Female: Follicular Phase: 5–25 international unit/24 h. Midcycle: 30–90 international unit/24 h. Luteal phase: 2–24 international unit/24 h. Postmenopausal: Greater than 40 international unit/24 h. Male: 7–25 international unit/mL.

Description

Luteinizing hormone (LH), a gonadotropic hormone secreted by the anterior pituitary gland, is needed (with follicle-stimulating hormone [FSH]) for ovulation to occur. After ovulation, LH aids in stimulating the corpus luteum in secreting progesterone. FSH values are frequently evaluated with LH values. In men, LH stimulates testosterone production, and with FSH, they influence the development and maturation of spermatozoa.

High-serum values are related to gonadal dysfunction, and low serum values are related to hypothalamus or pituitary failure. Women taking oral contraceptives have an absence of midcycle LH peak until the contraceptives are discontinued.

Purpose

- To evaluate hormonal therapy for inducing ovulation.
- To evaluate infertility in women and men.

Lymphocytes (T and B) (Blood)

T and B Lymphocytes, Lymphocyte Marker Studies, Lymphocyte Subset Typing

Reference Values

Adult: T Cells: 60–80%, 600–2400 cells/ μ L. B Cells: 4–16%, 50–250 cells/ μ L.

Description

The two categories of lymphocytes are T lymphocytes and B lymphocytes. The T lymphocytes are associated with cell-mediated immune responses (cellular immunity), such as rejection of transplant and graft, tumor immunity, and microorganism (bacterial and viral) death. If the surface of the host's tissue cell is altered, the T cells might perceive that altered cell as foreign and attack it. This might be helpful if the altered surface is a result of tumor development; however, this T-cell attack might give rise to autoimmune disease.

The B lymphocytes, derived from bone marrow, are responsible for humoral immunity. The B cells synthesize immunoglobulins to react to specific antigens. An interaction between T and B lymphocytes is necessary for a satisfactory immune response to occur.

Purpose

- To diagnose autoimmune diseases (i.e., immunosuppressive diseases such as acquired immunodeficiency syndrome [AIDS], lymphoma, and lymphocytic leukemia).
- To monitor changes during the treatment of immunosuppressive diseases.

Magnesium (Mg) (Serum)

Reference Values

Adult: 1.5–2.5 mEq/L, 1.8–3.0 mg/dL.

Child: *Newborn:* 1.4–2.9 mEq/L. *Child:* 1.6–2.6 mEq/L.

Description

Magnesium is most plentiful in the cells (intracellular fluid). One third of the magnesium ingested is absorbed through the small intestine, and the remaining unabsorbed magnesium is excreted in the stools. The absorbed magnesium is eventually excreted through the kidneys.

As with potassium, sodium, and calcium, magnesium is needed for neuromuscular activity. Magnesium influences use of potassium, calcium, and protein, and when there is a magnesium deficit, there is frequently a potassium and calcium deficit. Magnesium is also responsible for the transport of sodium and potassium across the cell membranes. Another function of magnesium is its activation of enzymes for carbohydrate and protein metabolism.

Magnesium is found in most foods, so it would be difficult for an individual who maintains a normal diet to have a magnesium deficiency. The daily required magnesium intake for an adult is 200–300 mg, or 0.2–0.3 g.

A serum magnesium deficit is known as hypomagnesemia, and a serum magnesium excess is called hypermagnesemia.

Purpose

- To detect hypomagnesemia or hypermagnesemia.
- To monitor magnesium levels when there is a probable loss.

Magnetic Resonance Imaging (MRI)

Normal Findings

Normal tissue, structure, and blood flow.

Description

Magnetic resonance imaging (MRI) produces cross-sectional images similar to those produced by computed tomography (CT); however, unlike CT, it does not use ionizing radiation and thus is free of the hazards presented by exposure to x-rays. The cost of MRI is approximately one third more than the cost of CT.

The MRI scanner consists of a magnet encased in a large, doughnut-shaped cylinder. The patient lies on a narrow table and is guided into the cylinder until the body part to be imaged is within the magnetic field. The hydrogen nuclei of the cells of the body respond like magnets to the magnetic field and align. When a radio-frequency wave is applied, the protons in the nuclei resonate, and when the radio-frequency wave is removed, the energy released by the protons as they relax is detected as a radio signal. This signal is interpreted by a computer and translated into cross-sectional images.

MRI is now the most sensitive technique for defining the structure of internal organs and for detecting edema, infarction, hemorrhage, blood flow, tumors, infections, and

Nursing Implications with Rationale

Magnetic Resonance Imaging

Pretest

- Elicit any problems with claustrophobia. Relaxation techniques or a sedative might be used.
- Ascertain from the patient the presence of a pacemaker, wire left in the body from a previous pacemaker, any metal prosthetics, or shrapnel left in the body, which could cause serious tissue injury as the result of the magnetic pull.
- Alert the physician or healthcare provider if patient is on an IV pump. MRI can disrupt IV flow.
- Assess the body for tattoos, especially those that include the color red, because they may become warm during the test.
- Provide emotional support.

Patient Teaching

- Explain the procedure. Inform the patient that various loud noises (clicking, thumping) from the scanner will be heard. Earplugs are available. Inform the patient that the MRI personnel will be in another room but can communicate via an intercom system. With an open MRI, a family member or friend may be in the room with the patient while the MRI scanning is taking place. This is also possible with closed MRI.
- Explain the need to remain still when instructed.
- Explain to the patient that there is no exposure to radiation. The contrast media that might be used is not iodinated contrast.
- Instruct the patient to remove watches, credit cards, hairpins, jewelry, and makeup. The magnetic field can damage a watch.
- Inform the patient that the MRI procedure is painless. Encourage the patient to relax during the testing.
- Caution patients with cardiac pacemakers not to approach the MRI unit.
- Inform the patient who has metal fillings in teeth that a “tingling sensation” may be felt during imaging.

plaques on the myelin sheath that cause multiple sclerosis. Many of these conditions would be difficult to distinguish using CT or conventional x-rays. It can differentiate between edema and tumor. MRI excels in diagnosing pathologic problems associated with the central nervous system (CNS), such as tumors, hemorrhage, edema, cerebral infarction, and subdural hematoma. Early after an ischemic stroke, diffusion-weighted imaging can detect the stroke's location and extent and can determine the severity of the damage to the brain tissue. MRI can visualize bone, joint, and soft tissue injuries. Bone artifacts do not occur, and MRI can identify a tumor adjacent to or within bony structures (e.g., pituitary gland tumor).

Pacemakers, wires left in the chest from a previous pacemaker, some aneurysm or some surgical intracranial clips, and certain hearing aids are contraindications to undergoing an MRI procedure. Jewelry, watches, keys, credit cards, and hair clips must be removed prior to the procedure. When an emergency situation occurs during imaging, the patient

must be moved from the MRI room so that resuscitation equipment can be used. MRI is difficult to use to study critically ill patients on life-support systems because of the effect of the magnet on the equipment.

MRI and CT can be used for similar tissue studies. MRI involves use of contrast media in certain circumstances, but the IV contrast for MRI is chemically unrelated to the iodinated contrast used in CT and conventional radiography. Presently the only commercially available contrast for MRI is gadolinium-DTPA. Gadolinium (Magnevist) and Feridex are frequently used to evaluate problems of the brain, base of the skull, and spine. This contrast agent can cross the “leaky” blood–brain barrier. Imaging can occur 5–60 minutes after the start of the gadolinium infusion.

Magnetic Resonance of the Brain and Spine (Intracranial [IC] MRI)

Intracranial MRI gives cross-sectional images of the brain and spine. It can detect neuropathology through the bone such as visualizing fluid (edema) within soft tissues. The IC-MRI can identify cerebral thrombosis caused by cerebrovascular accident (stroke), cerebral tumors, abscesses, or aneurysms, cerebral hemorrhage, and demyelinated nerve fibers (myelin sheaths) causing multiple sclerosis. It can also detail abnormalities of the spinal cord and degenerated discs.

Magnetic Resonance of The Heart and Coronary Arteries

Cine MRI, or ultrafast MRI, is a fast-moving MRI procedure that can image the heart in a continuous motion. It is useful for perfusion imaging, and it can determine the patency of coronary arteries following coronary grafts. Also, it is used to detect the viability of the myocardium and to assess chambers' volumes. The echo-planar MRI (EPI), like cine MRI, is used for rapid imaging of the heart and coronary arteries.

Magnetic Resonance Angiography

Magnetic resonance angiography (MRA) is a noninvasive means of displaying vessels by imaging. It maximizes the signals in structures containing blood flow and reconstructs only the structures with flow. It is useful for evaluating vascular lesions. Other structures of lesser interest are subtracted from the image by the computer.

Magnetic Resonance Spectroscopy

This MRI uses a scanner that can evaluate and detect ischemic heart disease and the effects of cancer treatment on tumors. It allows biochemical sampling of the tissue that is being imaged so that one can distinguish between a demyelinating condition and a neoplasm versus an infection without need for a biopsy. It can also confirm the presence of Alzheimer dementia, determine the extent of head injury due to trauma and stroke, and identify the cause of coma.

Purpose

- To detect central nervous system lesions, vascular problems, cardiac perfusion problems, injury, tumor, or edema.

Posttest

Monitor any effects resulting from the MRI. Answer patient questions or refer to appropriate health professional.

Procedure

- A consent form should be signed.
- Inform the patient that there will be no exposure to radiation.
- Empty bladder prior to the test.
- Remove all jewelry, including watches, glasses, hearing aids, hairpins, cosmetics that may contain metallic fragments, and any metal objects. The magnetic field can damage watches. Those with pacemakers are not candidates for MRI; some with metal prosthetics and those with nerve stimulating devices also may not be candidates. Remove dentures as advised.
- Occupational history is important. Metal in the body, such as shrapnel or flecks of ferrous metal in the eye, may cause critical injury, such as retinal hemorrhage or globe rupture.
- Contraindications include patients in the first trimester of pregnancy. MRI could cause excess heat in the amniotic fluid.
- With a closed MRI procedure, the patient must lie absolutely still on a narrow table with a cylinder-type scanner around the body area being scanned.
- Sedation may be needed if the patient having a closed MRI procedure is extremely claustrophobic. A patient receiving a sedative should not drive home; therefore, a family member or friend should be available to drive.
- An open MRI may be ordered for patients who are claustrophobic, obese, or confused or for children; a family member or friend may be present. A mirror is available to see outside during the procedure. Patients need to remain still during an open MRI procedure. An open MRI procedure uses a lower-field magnet than does a closed MRI procedure; hence, lesser quality images are usually produced by open MRI.
- Certain MRI studies require a noniodinated contrast medium (gadolinium DTPA), which usually is injected intravenously. Use of MR contrast medium may be contraindicated for those with kidney dysfunction; the contrast medium is excreted by the kidneys.
- Food and fluids are not restricted for adults. Children should be NPO for 4 hours prior to the procedure.
- The procedure takes approximately 45 minutes to 1.5 hours.

Blood Flow: Extremities

- The limb to be examined is rested in a cradlelike support. Reference sites to be imaged are marked on the leg or arm, and the extremity is moved into a flow cylinder.
- The procedure takes approximately 15 minutes for arms and 15 minutes for legs.

Factors Affecting Diagnostic Results

- Movement during the procedure will distort the imaging.
- Ferrous metal in the body could cause critical injury to the patient and distort the images.
- Nonferrous metal may produce artifacts that degrade the images if in proximity to the area being scanned.

Mammography (Mammogram)

Normal Findings

Normal ducts and glandular tissue; no abnormal masses.

Description

Mammography is an x-ray examination of the breasts that can detect a breast lesion approximately 2 years before it is palpable. A breast mass (neoplasm) cannot be clinically palpable until it is 1 cm in size, so it may take 5 years or longer to grow and be detectable. Benign cysts are seen on the mammogram as well outlined, clear lesions and tend to be bilateral, whereas malignant tumors are irregular and poorly defined and tend to be unilateral.

The mammogram can detect approximately 90% of breast malignancies; however, the test carries a 10% false-positive rate. A positive test should be confirmed by biopsy.

Technical improvements have been made in the equipment, mammographic units, and the recording system used for mammography. The use of radiographic grids has improved the imaging quality of mammograms by decreasing image density. With the use of grids, the visibility of small cancers is increased. Also, the use of magnification mammography has improved the capability to identify cancers; however, the magnification increases the patient's radiation dose by prolonging exposure time.

Purpose

- To screen for breast mass(es).
- To detect a breast cyst or tumor.

Procedure

- Food and fluids are not restricted.
- The patient removes clothes and jewelry from the neck to the waist and wears a paper or cloth gown that opens in the front. Powder and ointment on the breast should be removed to avoid false-positive results. No deodorants should be used.
- The patient is standing, and each breast (one at a time) rests on an x-ray cassette table. As the breast is compressed, the patient will be asked to hold her breath while the x-ray is taken. Two x-rays are taken of each breast.
- The procedure usually takes 15–30 minutes.

Factors Affecting Diagnostic Results

- Previous breast surgery can affect the reading of the x-ray film.
- Jewelry, metals, ointment, and powder could cause false-positive results.

Methemoglobin (Blood), Hemoglobin M, Hb M

Reference Values

Normal: Less than 1.5% of the total hemoglobin; 0.06–0.24 g/dL; 9.2–37.0 $\mu\text{mol/L}$ (SI units).

Positive: 20–70%: complaints of headache, dizziness, fatigue, tachycardia. Greater than 70%: death.

Description

Methemoglobin (Hb M) occurs when the deoxygenated heme (iron portion of hemoglobin) is oxidized to a ferric state. In the ferric state, the heme cannot combine with oxygen; thus, cyanosis without dyspnea or other cardiovascular problems may result. Methemoglobinemia may be acquired from chemicals, radiation, and such drugs as nitrites, nitrates, certain sulfonamides, and antimalarials, local anesthetics, or inherited enzyme deficiency. Poisoning from occupational or environmental contact could cause methemoglobinemia. A deficiency in the glucose-6-phosphate dehydrogenase (G6PD) enhances the production of Hb M.

If newborns are cyanotic after oxygen has been given, the methemoglobin level should be checked. Infants are more prone to develop methemoglobinemia.

Purpose

- To detect methemoglobin in the blood caused from an acquired chemical or drug condition.
- To detect congenital methemoglobinemia.

Myoglobin (Serum)

Reference Values

Adult: 12–90 ng/mL, 12–90 mcg/L.

Female: 12–75 ng/mL, 12–75 mcg/L.

Male: 20–90 ng/mL, 20–90 mcg/L.

Description

Myoglobin is an oxygen-binding protein, similar to hemoglobin, that is found in skeletal and cardiac muscle cells. Myoglobin is released into circulation after an injury. Increased serum myoglobin occurs about 2–6 hours following muscle tissue damage. Serum myoglobin level reaches its peak following a myocardial infarction (MI) in approximately 8–12 hours. Elevated serum myoglobin (myoglobinemia) is short lived; in 50% of individuals having an MI, the serum level begins to return to the normal range in 12–18 hours. Urine myoglobin may be detected for 3–7 days following muscle injury.

Because serum myoglobin is nonspecific concerning which muscle is damaged, myocardium or skeletal, cardiac enzymes should also be ordered. Creatine phosphokinase (CPK) and CPK isoenzyme, CPK-MB, should be checked because this enzyme rises early after an MI. Assessment of signs and symptoms of an acute MI needs to be considered along with the blood tests. This test is not performed following cardioversion or after an angina attack.

Purpose

- To detect myoglobin protein that is released during skeletal or cardiac muscle injury.

Occult Blood (Feces)

Reference Values

Adult: Negative.

Child: Negative.

Note: A diet rich in meats, poultry, and fish, and some drugs (cortisone, aspirin, potassium), could cause a false-positive

occult blood test. Urine and soap solution in the feces may affect the test result.

Description

Occult (nonvisible or hidden) blood in the feces usually indicates gastrointestinal bleeding and may be present days or several weeks after a single bleeding episode. Bright red blood from the rectum can be indicative of bleeding from the lower large intestine (e.g., hemorrhoids), and tarry black stools indicate blood loss of greater than 50 mL from the upper GI tract.

Purpose

- To detect blood in the feces.

Osmolality (Serum)

Reference Values

Adult: 280–300 mOsm/kg.

Panic Values: Less than 240 mOsm/kg and greater than 320 mOsm/kg.

Child: 270–290 mOsm/kg.

Description

Serum osmolality is an indicator of serum concentration. It measures the number of dissolved particles (electrolytes, urea, sugar) in the serum and is helpful in the diagnosis of fluid and electrolyte imbalances. Sodium contributes 85–90% of the serum osmolality; changes in osmolality usually result from changes in the serum sodium concentration. Double the serum sodium can give a rough estimate of the serum osmolality.

An increased value (greater than 300 mOsm/kg) indicates hemoconcentration due to dehydration; a decreased value (less than 280 mOsm/kg) indicates hemodilution due to overhydration, or water excess. An osmometer is used in laboratories to determine serum osmolality; however, if the serum sodium, urea, and sugar levels are known, the serum osmolality can be calculated by the nurse as follows.

$$\text{Serum osmolality} = 2 \times \text{Serum sodium} + \frac{\text{BUN}}{3} + \frac{\text{Sugar}}{18}$$

Purpose

- To monitor body fluid balance.
- To determine the occurrence of body fluid overload or dehydration.

Osmolality (Urine)

Reference Values

Adult: 50–1200 mOsm/kg H₂O, average 200–800 mOsm/kg H₂O.

Child: *Newborn:* 100–600 mOsm/kg H₂O. *Child:* Same as adult.

Description

The urine osmolality test is more accurate than the specific gravity test in determining the urine concentration, because its value reflects the number of particles, ions, and molecules

and is not unduly influenced by large molecules. Specific gravity measures the quantity and nature of the particles, such as sugar, protein, and IV dyes (these elevate specific gravity but have little effect on osmolality).

The urine osmolality fluctuates in the same way that the urine specific gravity does, and it can be low or high according to the patient's state of hydration. A dehydrated patient with normal kidney function could have a urine osmolality of 1000 mOsm/kg H₂O or more. When hemoconcentration occurs as a result of acidosis, shock, or hyperglycemia, the serum osmolality is elevated, and so should the urine osmolality be elevated.

If serum hypo-osmolality and hyponatremia occur with urine hyperosmolality, the problem is most likely the syndrome of inappropriate antidiuretic hormone secretion (SIADH). ADH causes water reabsorption from the kidney, thus diluting the serum.

Purpose

- To monitor body fluid balance.
- To determine the occurrence of body fluid overload or dehydration.

Ova and Parasites (O and P) (Feces), Cytology Test for Cervical Cancer

Reference Values

Adult: Negative.

Child: Negative.

Description

Parasites may be present in various forms in the intestine, including the ova (eggs), larvae (immature form), cysts (inactive stage), and trophozoites (motile form) of protozoa. It is vitally important to detect parasites so that proper treatment can be ordered. Some of the organisms identified are amoeba, flagellates, tapeworms, hookworms, and roundworms. A history of recent travel outside the United States should be reported to the laboratory, because it may help in identifying the parasite.

Purpose

- To identify specific ova and parasites in fecal matter.

Papanicolaou Smear (Pap Smear), Cytology Test for Cervical Cancer

Normal Findings

No abnormal or atypical cells.

Description

The Pap (Papanicolaou) smear is used as a screening tool. Because malignant tissue changes usually take many years, yearly examination of exfoliative cervical cells (cells that have sloughed off) allows detection of early, precancerous conditions. It is suggested that women have their first Pap within 3 years of the onset of sexual intercourse or at age 21. Women younger than 30 should have yearly standard Pap

tests, but every 2 years is recommended if a liquid-based thin prep system is used. Women older than 30 should have a different screening frequency depending on their risk factors.

1. Women with a history of two normal yearly Pap tests in a row can be screened every 2–3 years with cessation of screening in low-risk women at age 65 years.
2. Women with a normal Pap test and a human papillomavirus (HPV) test that is negative for high-risk HPV type can be screened every 3 years. More often than every 3 years is not necessary because these women are at low risk for abnormal cervical cell changes.

Women with the following risk factors require yearly or more frequent screening:

- Using birth control pills
- Having sex with someone who has multiple sexual partners
- Having three or more sexual partners in a lifetime
- Starting sexual intercourse before age 18
- Sexual intercourse with partners who have HPV
- Cigarette smoking
- Being infected with chlamydia
- Being infected with high-risk type HPV
- Having an impaired immune system
- A history of treatment for abnormal cervical cell changes or cervical cancer
- Infection with HIV (two Pap tests in the first year after diagnosis and yearly after that)
- Exposure to diethylstilbestrol (DES) in utero (rare).

The Pap smear (cytology) results are reported by The Bethesda System (TBS). General categories of TBS are as follows:

- I. Within normal limits. TBS will also identify if the sample is adequate.
- II. Abnormal changes
 - A. Benign cellular changes
 1. Differentiates reactive or inflammatory changes from true dysplastic changes.
 2. Most important features of TBS. *Management:* Repeat smears yearly or as determined by the patient's healthcare provider..
 - B. Epithelial abnormalities
 1. Atypical squamous cells of undetermined significance (ASCUS): Favoring a neoplastic process or a reactive process. *Management:* Repeat smears at closer intervals; recall for colposcopy and/or combine repeat cytology with cervicography or HPV-DNA type.
 2. Low-grade squamous intraepithelial lesion (LSIL): Shows the earliest abnormal nuclear changes; combines diagnosis of HPV, mild dysplasia, and cervical intraepithelial neoplasia (CIN 1). *Management:* Repeat cytology at close intervals; recall for colposcopy.
 3. High-grade squamous intraepithelial lesion (HSIL): Includes moderate and severe dysplastic

changes, carcinoma in situ (CIS 1), CIN 2, and CIN 3. *Management:* Recall for colposcopy.

4. Squamous cell carcinoma: Changes consistent with invasive cancer. *Management:* Recall for colposcopy.
5. Glandular cell abnormalities
 - a. Atypical cells of undetermined significance, atypical endocervical cells or endometrial cells. *Management:* In young women, check for endocervicitis; repeat smear; refer for colposcopy. In older women, refer for colposcopy with endocervical sample.
 - b. Adenocarcinoma. *Management:* Refer for colposcopy.

For suggestive or positive Pap smears, colposcopy and/or a cervical biopsy are frequently ordered to confirm the test results. Atypical cells can occur following cervicitis and after excessive or prolonged use of hormones.

Purpose

- To detect precancerous and cancerous cells of the cervix.
- To assess the effects of sex hormonal replacement.
- To identify viral, fungal, and parasitic conditions.
- To evaluate the response to chemotherapy or radiation therapy to the cervix.

Nursing Implications with Rationale Papanicolaou Smear

- Explain the procedure to the patient. Emphasize to the patient that she should not douche, insert vaginal suppositories, or have sexual intercourse for at least 24 hours (some say 48 hours) before the Pap smear. Douching could wash away the cervical cells.
- Obtain a patient history regarding menstruation and any menstrual problems (i.e., the last menstrual period, bleeding flow, vaginal discharge, itching, and whether she is taking hormones or oral contraceptives).
- Answer the patient's questions, and refer questions you cannot answer to other health professionals. Try to alleviate the patient's anxiety, if at all possible. Be a good listener.
- Label the slide with the patient's name and the date. The laboratory slip should include the patient's age and the specimen site(s).

Patient Teaching

- Inform the patient that a manual examination of the vagina, lower abdomen, rectum, and breast may or will follow the Pap smear.
- Emphasize that a pelvic exam is different from a Pap smear and that both are important.
- Explain to the patient that the frequency of the test depends on her risk factors and as determined by her healthcare provider. (See section on risk factors under Description).
- Inform the patient that test results should be back in 7–10 days. Physicians and healthcare providers differ in the way they report test results; provide the patient with information about how test results will be shared with the patient.

Procedure

- Food and fluids are not restricted.
- The patient should not douche, insert vaginal medications, or have sexual intercourse for at least 24 hours (preferably 48 hours) before the test. The test should be done between menstrual periods.
- The patient is generally asked to remove all clothes, because the breasts are examined after the Pap smear is taken. A paper or cloth gown is worn.
- Instruct the patient to lie on the examining table in the lithotomy position (heels in stirrups).
- A speculum is inserted into the vagina. The speculum may be lubricated with warm running water.
- A curved spatula (Pap stick) or a spatula/brush combination is used to scrape the cervix. The obtained specimen is transferred onto a slide and sprayed with a commercial fixation spray, or the whole stick is immersed in a container of liquid-based fixative. Label the slide or container with the patient's name and date.
- The Pap smear procedure takes approximately 10 minutes.

Factors Affecting Diagnostic Results

- Allowing cells to dry on the slide before using the fixative solution or spray can affect results.
- Douching, use of vaginal suppositories, or sexual intercourse within the 24 hours before the test can interfere with the results.
- Menstruation can interfere with the test results.
- Drugs (i.e., digitalis preparations, tetracycline, female hormones) could change the cellular structure.
- Lubricating jelly on the speculum can interfere with test results.
- Inadequate specimen. Note that liquid-based collection reduces the rate of inadequate results by 90%.

Parathyroid Hormone (PTH) (Serum)

Parathormone

Reference Values

Adult: *Intact PTH:* 11–54 pg/mL. *C-Terminal PTH:* 50–330 pg/mL. *N-Terminal PTH:* 8–24 pg/mL.

Description

Parathyroid hormone (PTH) is secreted by the parathyroid glands. PTH regulates the concentration of calcium and phosphorus in the extracellular fluid by promoting calcium reabsorption and phosphorous excretion. Low serum calcium levels stimulate the secretion of PTH while high serum calcium levels inhibit PTH secretion.

Two forms of PTH, inactive C-terminal PTH and active N-terminal PTH, are used in diagnosing parathyroid disorders (Kee, 2018).

Purpose

- To identify hypo- or hyperparathyroidism.
- To monitor the patient's response to PTH therapy.

Partial Thromboplastin Time (PTT), Activated Partial Thromboplastin Time (APTT) (Plasma)

Reference Values

Adult: Results vary in accordance with equipment and laboratory values. *PTT*: 60–70 seconds. *APTT*: 20–35 seconds.

Child: Increased above adult level.

Anticoagulant Therapy: 1.5–2.5 times the control in seconds.

Note: Most laboratories do APTT only.

Description

The APTT is similar to the PTT, except that the thromboplastin reagent used in the APTT test contains an activator (kaolin, celite, or ellagic acid) for identification of deficient factors. This test is commonly used to monitor heparin therapy.

The APTT is more sensitive in detecting clotting factor defects than the PTT, because the activator added in vitro shortens the clotting time. By shortening the clotting time, minor clotting defects can be detected.

Purpose

- To monitor heparin therapy.
- To screen for clotting factor deficiencies except VII and XIII.
- To detect platelet variations.

Phenothiazines (Serum)

Reference Values

Adult:

Drug	Therapeutic Range	Peak Time	Toxic Level
Chlorpromazine (Thorazine)	50–300 ng/mL	2–4 h	>750 ng/mL
Prochlorperazine (Compazine)	50–300 ng/mL	2–4 h	>1000 ng/mL
Thioridazine (Mellaril)	100–600 ng/mL 0.2–2.6 mg/L	2–4 h	>2000 ng/mL >10 mg/L
Trifluoperazine (Stelazine)	50–300 ng/mL	2–4 h	>1000 ng/mL

Description

Phenothiazines are major tranquilizers (neurolytics) used for the treatment of psychosis and emesis. Although they have a wide therapeutic index, an extremely large overdose can cause drug toxicity.

Purpose

- To monitor a specific phenothiazine level for therapeutic effect.
- To check for specific phenothiazine toxicity.

Phenytoin Sodium (Serum)

Reference Values

Therapeutic Range: *Adult*: As an anticonvulsant, 10–20 mcg/mL, 39.6–79.3 μ mol/L (SI units). As an anti-arrhythmic, 10–18 mcg/mL, 39.6–71.4 μ mol/L (SI units). *In Saliva*: 1–2 mcg/mL, 4–9 μ mol/L (SI units).

Toxic Level: *Adult*: Greater than 20 mcg/mL, greater than 79.3 μ mol/L (SI units). *Child*: greater than 15–20 mcg/mL, 56–79 μ mol/L (SI units).

Description

Phenytoin (Dilantin) is a medication that reduces voltage, frequency, and transmission of electrical discharges within the motor cortex. It is used to prevent and control grand mal seizures as well as an antiarrhythmic for decreasing the force of myocardial contraction, improving atrioventricular conduction depressed by a digitalis preparation, and prolonging the refractory period of the heart contraction.

The average half-life is 24 hours in adults and 15 hours in children. Because it takes 5–10 days for phenytoin to achieve a steady state, the serum phenytoin level should be monitored frequently to check the therapeutic level and to avoid a toxic level (Kee, 2018).

Purpose

- To monitor phenytoin (Dilantin) levels.

Phosphorus (P)—Inorganic (Serum)

Phosphate (PO_4)

Reference Values

Adult: 1.7–2.6 mEq/L or 2.5–4.5 mg/dL; 0.78–1.52 mmol/L (SI units).

Child: *Newborn*: 3.5–8.6 mg/dL. *Infant*: 4.5–6.7 mg/dL. *Child*: 4.5–5.5 mg/dL.

Older Adult: Slightly lower than adult.

Description

Phosphorus is the principal intracellular anion; however, most phosphorus exists in the blood as phosphate. From 80 to 85% of the total phosphates in the body are combined with calcium in the teeth and bones.

Phosphorus is the laboratory term used, because phosphates are converted into inorganic phosphorus for the test. Functions of phosphorus include metabolism of carbohydrates and fats, maintenance of the acid–base balance, use of B vitamins, promotion of nerve and muscle activity, and transmission of hereditary traits.

Phosphorus (P) metabolism is associated with calcium (Ca) metabolism. Both ions need vitamin D for their absorption from the gastrointestinal tract. Phosphorus and calcium concentrations are controlled by the parathyroid hormone. Usually there is a reciprocal relationship between calcium and phosphorus: When serum phosphorus levels increase, serum calcium levels decrease, and when serum phosphorus levels decrease, serum calcium levels increase. In certain neoplastic bone diseases, this relationship may be altered.

A high serum phosphorus level is called *hyperphosphatemia*, which is usually associated with kidney dysfunction (poor urinary output). *Hypophosphatemia* means a low serum phosphorus level.

Purpose

- To monitor phosphorus levels during renal insufficiency or failure.
- To compare phosphorus level with those of other electrolytes.

Platelet Aggregation and Adhesions (Blood)

Reference Values

Adult: Aggregation in 3–5 minutes.

Description

The **platelet aggregation test** measures the ability of platelets to adhere to each other when mixed with an aggregating agent such as collagen, ADP, or ristocetin. Increased bleeding tendencies result from a decrease in platelet aggregation time.

The **platelet adhesion test** is used for the same purposes as described for the platelet aggregation test and is also performed for patients taking large doses of aspirin for several weeks and for individuals who have a prolonged bleeding time. It is not performed in many laboratories because of the difficulty in standardizing the technique.

Purpose

- To detect abnormalities in platelet function.
- To aid in diagnosing hereditary and acquired platelet deficiencies such as von Willebrand disease.

Platelet Count (Blood—Thrombocytes)

Reference Values

Adult: 150,000–400,000 μL (mean: 250,000 μL), $0.15\text{--}0.4 \times 10^{12}/\text{L}$ (SI units).

Child: *Premature*: 100,000–300,000 μL . *Newborn*: 150,000–300,000 μL . *Infant*: 200,000–475,000 μL .

Description

Platelets (thrombocytes) are basic elements in the blood that promote coagulation. Platelets are much smaller than erythrocytes. They clump and stick to rough surfaces and injured sites when blood coagulation is needed. A decrease in circulating platelets of less than 50% of the normal value will cause bleeding; if the decrease is severe (less than 50,000 μL), hemorrhaging might occur.

Thrombocytopenia means platelet deficiency or a low platelet count. It is commonly associated with leukemias, aplastic anemia, and idiopathic thrombocytopenic purpura. Increased platelet counts (thrombocytosis) occur in polycythemia, in fractures, and after splenectomy.

Purpose

- To check the platelet count.
- To monitor the platelet count during cancer chemotherapy.

Positron Emission Tomography (PET)

Normal Findings

Normal brain, heart, lung, and gastrointestinal activities and blood flow.

Description

Positron emission tomography (PET), a relatively noninvasive test, measures the body's abnormal molecular cell activity. Myocardial perfusion abnormalities can be determined at rest and after administration of dipyridamole (Persantine).

Most PET imagers have several radiation detector rings. Each detector group represents a profile or one-dimensional projection of the radioactivity distribution in a tomographic slice. These profiles are combined to produce a cross-sectional (tomographic) image. The 2D PET images are reconstructed from projection data derived from the detector rings. Three-dimensional PET imaging is a new approach in which images are generated from the 2D images.

The patient receives a substance tagged with a radionuclide (i.e., radioactive glucose, rubidium-82, oxygen-15, nitrogen-13). Fluorodeoxyglucose (FDG) is the most common radioisotope used in PET. Tomographic slices from cross-sections of tissue are detected and visually displayed by computer. PET is most effective in determining blood flow to the brain and heart. Radiation from PET is a quarter of that received from computed tomography.

Purpose

- To detect a decreased blood flow or perfusion with coronary artery disease.
- To determine the size of infarct and myocardial viability.
- To detect transient ischemia.
- To detect viable myocardium.
- To detect decreased oxygen utilization and decreased blood flow with brain disorders such as cerebral vascular accident (CVA).
- To differentiate between types of dementia.
- To identify stages of cranial tumors.
- To identify lung nodules and colorectal metastases.
- To differentiate between benign and malignant lesions.
- To stage malignant lesions and disease.
- To monitor a response to therapy.

Procedure

- A consent form should be signed.
- Nothing by mouth (NPO) 4–6 hours prior to the study.
- No coffee, alcohol, or tobacco is allowed for 24 hours before the test.

B-58 Appendix B Diagnostic Values and Laboratory Tests

- CT or MRI scans less than 6 weeks old should be available for the purpose of comparison.
- Any laboratory or biopsy reports should be available. Glucose levels are required if a study with fasting glucose is being performed.
- Start two IVs, one for the radioactive substance and the second to draw blood gas samples.
- For certain brain studies, a blindfold may be used to keep the patient from being distracted.
- For brain studies, the patient's head is placed in a holder to restrict movement. For heart or abdominal studies, Velcro straps are used to restrict body motion.
- No sedatives are given, because the patient needs to follow instructions.
- Have patient empty the bladder 1–2 hours before the test if imaging the pelvis.
- Test takes 1–2 hours.

Factors Affecting Diagnostic Results

- Anxiety could interfere with test results.
- Sedatives given might prevent patient from following directions.

Potassium (K) (Serum)

Reference Values

Adult: 3.5–5.3 mEq/L; 3.5–5.3 mmol/L (SI units).

Panic Values: Less than 2.5 mEq/L and greater than 7.0 mEq/L.

Child: *Newborn*: 3.8–5.8 mEq/L. *Infant*: 3.5–5.5 mEq/L. *Child*: 3.5–4.8 mEq/L.

Description

Potassium is the electrolyte found most abundantly in intracellular fluids (cells). The serum potassium level has a narrow range, and cardiac arrest could occur if the serum level is less than 2.5 mEq/L or greater than 7.0 mEq/L.

Eighty to 90% of the body potassium is excreted by the kidneys. When tissue breakdown occurs, potassium leaves the cells and enters the extracellular fluid (interstitial and intravascular fluids). With adequate kidney function, the potassium in the intravascular fluid (plasma/blood vessels) will be excreted, and with excessive potassium excretion, a serum potassium deficit (hypokalemia) occurs. However, if the kidneys are excreting less than 600 mL of urine daily, potassium will accumulate in the intravascular fluid and serum potassium excess (hyperkalemia) will occur.

The body does not conserve potassium, and the kidneys excrete an average of 40 mEq/L daily (the range is 25–120 mEq/L/24 h), even with a low dietary potassium intake. The daily potassium requirement is 3–4 g, or 40–60 mEq/L.

Purpose

- To detect the presence of hypo- or hyperkalemia.
- To monitor potassium levels during health problems and with certain drugs.

Progesterone (Serum)

Reference Values

Adult: *Female*: Follicular Phase: 0.1–1.5 ng/mL, 20–150 ng/dL. Luteal Phase: 2–28 ng/mL, 250–2800 ng/dL. Postmenopausal: Less than 1.0 ng/mL, less than 100 ng/dL. *Pregnancy*: First Trimester: 9–50 ng/mL. Second Trimester: 18–150 ng/mL. Third Trimester: 60–260 ng/mL. *Male*: Less than 1.0 ng/mL, less than 10 ng/dL.

Description

Progesterone, a hormone produced primarily by the corpus luteum of the ovaries and in a small amount by the adrenal cortex, peaks during the luteal phase of the menstrual cycle for 4–5 days and during pregnancy. It prepares the endometrium for implantation of the fertilized egg. Only a small amount of progesterone is detected in the blood, because most is metabolized in the liver to pregnanediol, a progesterone metabolite.

A urine pregnanediol might be ordered to verify serum progesterone results.

Purpose

- To aid in the diagnosis of an ovarian or adrenal tumor.
- To aid in the diagnosis of placental failure.
- To evaluate infertility problems resulting from a decreased progesterone level.

Nursing Implications with Rationale Positron Emission Tomography

Pretest

- Check that a consent form has been signed.
- Assess the IV site, monitor vital signs.
- Listen to the patient's concerns.

Patient Teaching

- Inform the patient that instructions given during the test should be followed.
- Inform the patient that a head holder or Velcro straps could be used for the restriction of body movement during imaging.

Posttest

- Continue to monitor vital signs.
- Avoid postural hypotension by slowly moving the patient to upright position.
- Increase fluid intake to remove radioisotope from the bladder.

Patient Teaching

- Explain to the patient that the radiation from the test is short lived and that the test is considered to be a relatively noninvasive test.
- Encourage the patient to remain relaxed and to avoid stress. The patient should not sleep but should remain quiet and still.
- Instruct the patient to take fluids posttest to help eliminate the radioactive substance.

Prolactin (PRL) Serum, Lactogenic Hormone, Lactogen

Reference Value

Female: *Nonpregnant*: Follicular Phase: 0–23 ng/mL. Luteal Phase: 0–40 ng/mL. Postmenopausal: Less than 12 ng/mL. *Pregnant*: First Trimester: Less than 80 ng/mL. Second Trimester: Less than 160 ng/mL. Third Trimester: Less than 400 ng/mL.

Male: 0.1–20 ng/mL.

Pituitary Adenoma: Greater than 100–300 ng/mL.

Description

Prolactin, a hormone secreted by the anterior pituitary gland, is necessary in the development of the mammary glands for lactation and for stimulating and maintaining lactation postpartum. If the mother does not breastfeed, serum prolactin falls to normal range.

Serum prolactin levels of 100–300 ng/mL in nonpregnant females and in males may indicate a pituitary adenoma (tumor). Bromocriptine (Parlodel) decreases the serum prolactin level and slows tumor growth until the pituitary tumor can be removed.

Purpose

- To determine the effects of surgery, chemotherapy, and/or radiation for treating prolactin-secreting tumors.
- To detect various health problems.
- To check drugs that the patient is taking that influence increased prolactin levels.

Prostate-Specific Antigen (PSA) (Serum)

Reference Values

PSA: *Normal*: Less than 4 ng/mL. *Benign Prostatic Hyperplasia (BPH)*: 4–10 ng/mL. *Prostate Cancer*: 10–120 ng/mL (depends on the stage of prostate cancer).

Total PSA: *Normal*: 2.5–4 ng/mL

Free PSA: *Normal*: Greater than 1 ng/mL

% Free PSA: *Normal*: Greater than 25%

Description

Prostate-specific antigen (PSA), a glycoprotein from the prostatic tissues, is increased in both benign prostatic hyperplasia (BPH) and prostatic cancer; however, it is markedly increased in prostatic cancer. The PSA value may also be increased after a rectal examination and prostate surgery.

An annual PSA test should be started at the age of 50. It should be started at the age of 40 if the man has a familial history of prostate cancer or is African American. A digital rectal exam (DRE) is usually done along with a PSA test. With an abnormal DRE, a biopsy of the prostate gland may be performed regardless of whether the PSA test is normal or elevated. If the PSA is greater than 10 ng/mL, there is a 70% chance the prostate gland has a malignancy. Doubling the time of PSA results in 12 months is a concern—for example, from 2.0 to 4.0 ng/mL. Also, an elevated PSA could be

due to an enlarged prostate gland, such as benign prostatic hyperplasia [BPH]) or prostatitis, which is inflammation of the prostate gland from a bacterial infection or other causes.

The serum PSA may be used to monitor the effect of prostate cancer treatment with chemotherapy or radiation, determine disease process and prognosis, and detect a recurrence of the tumor. Repeating the PSA test may be necessary.

Purpose

- To aid in the diagnosis of prostate cancer.
- To monitor the effect of prostate cancer treatment.
- To determine disease process and prognosis.
- To detect a recurrence of the tumor.

Protein (Total) (Serum)

Reference Values

Adult: 6.0–8.0 g/dL.

Child: *Premature*: 4.2–7.6 g/dL. *Newborn*: 4.6–7.4 g/dL.

Infant: 6.0–6.7 g/dL. *Child*: 6.2–8.0 g/dL.

Description

The total protein is composed mostly of albumin and globulins. The use of the total serum protein test is limited unless the serum albumin, A/G ratio, or protein electrophoresis test is also performed.

The protein level needs to be known to determine the significance of its components. With certain disease entities (i.e., collagen diseases, cancer, and infections), the total serum protein levels may be normal when the protein fractions are either decreased or elevated.

Purpose

- To differentiate between albumin and globulin.
- To monitor protein levels.
- To identify selected health problems associated with protein deficit.

Protein (Urine)

Reference Values

Random Specimen: *Negative*: 0–5 mg/dL. *Positive*: 6–2000 mg/dL (trace to +2).

24-Hour Specimen: 25–150 mg/24 h.

Description

Proteinuria is usually caused by renal disease due to glomerular damage and/or impaired renal tubular reabsorption. With a random urine specimen, protein can be detected using a reagent strip or dipstick, such as Combistix. Normally albumin is measured with the dipstick, because it is sensitive to a reagent strip. A positive urine specimen (proteinuria) suggests that a 24-hour urine specimen be obtained for quantitative analysis of protein.

The amount of proteinuria in 24 hours is an indicator of the severity of renal involvement. Minimal proteinuria (less than 500 mg or 0.5 g/24 h) may be associated with chronic pyelonephritis; moderate proteinuria (500–4000 mg or

0.5–4 g/24 h) may be associated with acute or chronic glomerulonephritis or toxic nephropathies (i.e., use of aminoglycosides [gentamicin]); and marked proteinuria (greater than 4000 mg or greater than 4 g/24 h) may be associated with nephrotic syndrome.

Emotions and physiologic stress may cause transient proteinuria. Newborns may have an increased proteinuria during the first 3 days of life.

Purpose

- To identify renal dysfunction with increased protein level in the urine.
- To determine the severity of renal involvement.
- To compare urine protein level with serum protein level.

Prothrombin Time (PT) (Plasma)

Reference Values

Adult: 10–13 seconds (depending on the method and reagents used) or 70–100%. *For Anticoagulant Therapy:* 1.5–2.0 times the control in seconds or 20–30%. INR (international normalized ratio): 2.0–3.0.

Child: Same as adult.

Description

Prothrombin (factor II of the coagulation factors) is synthesized by the liver and is an inactive precursor in the clotting process. Prothrombin is converted to thrombin by the action of thromboplastin, which is needed to form a blood clot.

The prothrombin time (PT) measures the clotting ability of factors I (fibrinogen), II (prothrombin), V, VII, and X. Alterations of factors V and VII will prolong the PT for about 2 seconds, or 10% of normal. In liver disease the PT is usually prolonged, because the liver cells cannot synthesize prothrombin.

International Normalized Ratio (INR)

It has been recommended that the PT be reported as an international normalized ratio (INR). The INR was devised to improve the monitoring process for warfarin anticoagulant therapy. A patient's response to the same dose of warfarin varies, thus the INR is used because it is an internationally standardized test for PT. The INR is designed for long-term warfarin therapy, and should only be used after the patient has been stabilized on warfarin. Stabilization takes at least 1 week. The INR should not be used when the patient is beginning warfarin therapy in order to avoid misleading test results. The target INR range for a patient having heart valve replacement is 2.5–3.5.

Purpose

- To monitor oral anticoagulant therapy (i.e., with bishydroxycoumarin [dicumarol] and warfarin sodium [Coumadin]).

Pulmonary Function Tests

Normal Findings

Normal values according to patient's age, gender, and height; greater than 80% of the predicted value. Also 95%

confidence levels are being used; these confidence ranges give a normal and a low or minimal normal value. This is done to account for physiologic differences in body types.

Description

In pulmonary physiology testing, the lungs are monitored by many complex devices and tests. The most basic device is the spirometer; it is used to measure flows, volumes, and capacities.

A number of pulmonary tests are conducted, because no single measurement can evaluate pulmonary performance. The most frequently performed PFTs are the slow vital capacity tests; lung-volume tests; forced vital capacity, flow-volume loop, and diffusion study tests; bronchodilator response studies; exercise studies; and nutritional studies.

Pulmonary Function Tests

1. Slow Vital Capacity (SVC) Tests

- *Tidal volume (TV, V_t):* The amount of air inhaled and exhaled during rest or quiet respiration or normal breathing.
- *Inspiratory capacity (IC):* The maximal inspired amount of air from end-expiratory tidal volume in normal breathing.
- *Expiratory reserve volume (ERV):* The maximal amount of air that can be exhaled from end-expiratory tidal volume in normal breathing.
- *Inspiratory reserve volume (IRV):* The maximal amount of air that can be inspired from end-inspiratory tidal volume in normal breathing.
- *Vital capacity (VC):* The maximal amount of air exhaled after a maximal inhalation:

$$VC = ERV + IC$$

Note: These pulmonary measurements are done slowly, without force. Individuals with obstructive lung disease will be able to expire more volume with this test than during the forced vital capacity maneuver that may lead to early airway closure and air trapping known as hyperinflation.

2. Lung Volume Studies

- *Lung volume tests using indicator gas:* Helium dilution and nitrogen washout are special studies that use the data generated in the slow vital capacity test to obtain the lung volumes. Tracer gases such as 10% helium or 100% oxygen are required. Using one of the gases, the person breathes in and out as the tracer gas is equilibrated in the lung; the functional residual capacity (FRC) is calculated from the changes. This method will tend to underestimate the value in individuals with advanced obstructive lung disease. This underestimation is a result of the trapped air in the lung, which does communicate with the airways.
- *Lung volumes by plethysmography method:* Lung volumes can be obtained by total body plethysmography. Body plethysmography uses a device that resembles an airtight telephone booth in which the subject sits. This method is a more accurate means to measure total volume of the lungs than the tracer gas method. Volumes measured in the box will be

larger than by the indicator gas method. The body plethysmography is able to measure trapped air that does not communicate with the airways.

- *Residual volume (RV)*: The amount of air that remains in the lungs after maximal expiration:

$$RV = FRC - ERV$$

- *Functional residual capacity (FRC)*: The amount of air left in the lungs after tidal or normal expiration:

$$FRC = ERV + RV$$

In obstructive disorders, FRC is increased because of hyperinflation and/or air trapping in the lungs. This value may normalize in patients with asthma post-exacerbation but will not for patients with COPD. In classical restrictive disorders, FRC, TLC, and RV are all reduced.

- *Total lung capacity (TLC)*: The total amount of air that is in the lungs at maximal inspiration:

$$TLC = VC + RV \text{ or } TLC = FRC + IC$$

3. Lung Volumes and Capacity

- *Forced vital capacity (FVC)*: The maximal amount of air that can be forced out of the lungs as hard, as fast, and as long as possible before a forceful inspiration. In obstructive lung disease, the FVC is decreased; in restrictive lung disease, the FVC is normal or decreased.

$$FVC = IC + ERV$$

- *Forced inspiratory volume (FIV)*: The greatest amount of air inhaled after a maximal expiration.
- *Forced expiratory volume timed (FEV_T)*: This value reflects the airflow through the bronchial tubes from the greatest to the smallest. It is reported as a time-based value as in 0.5 second FEV_{0.5}, 1 second FEV₁, 2 seconds FEV₂, and 3 seconds FEV₃. The American Thoracic Society (ATS) has suggested reporting the FEV₆, which is the amount of air expired in 6 seconds. This reflects the minimum exhalation time suggested for a forced vital capacity maneuver. The parameter of choice for evaluation of patients with asthma and other obstructive lung disease and to evaluate the response to bronchodilator therapy is still FEV₁. An improvement of greater than 15% after bronchodilator therapy is considered significant and indicates the presence of reversible airway obstruction, such as bronchospasm.

4. Flow-Volume Loop (FVL)

Another method to visualize FVC measurement is by graphing flow versus volume. This test yields the same basic information as the FVC test, but in addition provides useful visual information, for example, information concerning small-airway disease and upper airway obstruction. Its usefulness in screening people with some types of sleep disorder problems has been recently documented. It is used as a noninvasive tool to evaluate patients who may have some type of upper airway obstruction from thermal injury, polyps on the vocal cords, vocal cord paralysis, edema of

the epiglottis, scar tissue from old tracheotomy site, or floppy trachea.

- *Peak expiratory flow (PEF)*: The highest flow rate achieved at the beginning of the FVC; reported in liters per second. *Note*: Peak flow meters measure in liters per minute.
- *Peak inspiratory flow (PIF)*: The highest flow rate achieved at the beginning of the forced inspiratory capacity.
- *Forced expiratory flow (FEF)*: The FEF looks at flow at 25%, 50%, and 75% of the FVC and evaluates flow in various-size airways. It can evaluate the effectiveness of bronchodilator therapy. FEF 25% reflects flow through large airways; FEF 50% reflects flow through medium airways; and FEF 75% reflects flow through small airways. Decreased FEF 75% indicates small-airway disease.

5. Diffusion Capacity Test

Diffusion tests can be done using a number of techniques. The most commonly used is the single-breath test. This requires the patient to inspire from RV to TLC. The gas inhaled is a mixture of helium 10%, carbon monoxide 0.3%, and oxygen 21%, with the balance being nitrogen. The patient holds her breath for 10 seconds prior to expiration. After the first 750 mL is discarded to wash out dead-space gas, an alveolar sample is collected in a bag and analyzed for helium and carbon monoxide concentration. Results of this reflect the state of the alveolar capillary barrier.

Decreased diffusing capacity occurs in such disease states as interstitial fibrosis, pulmonary edema, and emphysema. It will also decrease in individuals with abnormal hemoglobin, such as occurs in anemias, including methemoglobin and increased carboxyhemoglobin in smokers. Cardiac output can affect this result. Increased DLCO values can be caused by pulmonary hemorrhage.

6. Bronchial Provocation Studies

Inhalation of pharmacologic and antigenic substances is used to test the sensitivity or hyperreactivity of the airways. Types of challenge would include methacholine, histamine, ASA, cold air, hypertonic saline, antigens, and others. Serial spirometry tests are performed to document the amount or degree of reactivity (a drop in FEV₁ greater than 20% of baseline spirometry). A baseline test followed by a challenge substance is given first, followed by a bronchodilator to ensure reversal. Indications for these tests are (1) normal spirometry test, (2) a history of symptoms such as wheezing, or coughing without a cause, and (3) symptoms related to exposure to industrial substances.

Methacholine chloride is usually the testing drug of choice because it causes bronchoconstriction rapidly. The patient inhales progressively larger doses of the drug until all levels are administered without a change in FEV₁ or until a drop of 20% of baseline FEV₁ is reached. The drug is then reversed by administration of a bronchodilator.

7. Exercise Studies

Pulmonary function studies are done at a resting or static state. Exercise studies evaluate the patient

during an active or dynamic state. These tests are performed by having the subject walk on a treadmill or pedal an ergometer to a set protocol to stimulate activity at progressive workloads. During this test, the heart rate and rhythm are monitored by a 12-lead electrocardiogram (ECG). The patient will also be breathing through a mouthpiece during the test to measure ventilation, expired carbon dioxide (VCO_2), and oxygen consumption (VO_2). Blood gases may be drawn at rest and at peak exercise. Pulse oximetry may also be monitored, as well as blood pressure. These tests are used to determine the amount of disability and to evaluate individuals with exertion dyspnea. This information can lead to an exercise prescription for activities for fitness programs and pulmonary and cardiac rehabilitation.

Types of exercise testing can be designed to simulate activity-related problems, of which *exercise-induced bronchospasm (EIB)* is an example. A common complaint of patients active in sport activities is bronchospasm. Several theories suggestive of the cause include an allergy-triggered airway, production of nitric oxide by the airway, hyperreactivity in association with physical activity, and mouth breathing required when the participant increases activity. When the individual breathes rapidly in and out through the mouth, the nose, which warms and filters air, is bypassed. This dry air causes chilling of the airway, leading to instability of the airways; it can also lead to bronchoconstriction in some individuals.

8. Pulse Oximetry (POX)

This is a noninvasive procedure to measure the oxygen saturation (SaO_2) of the blood. The device measures the SaO_2 by passing two wavelengths of infrared light through an extremity such as a finger. The device (sensor probe) measures the saturation of oxyhemoglobin in the pulsatile fraction of blood. This method is an excellent noninvasive trending device. When values vary, a blood gas analysis of the partial pressure of oxygen (PO_2) and/or CO-oximetry to measure oxyhemoglobin ($\%HbO_2$) and SaO_2 should be done to validate the results. A note of caution: Blood gas analyses normally do not measure SaO_2 ; they are calculated. Check with your blood gas laboratory for this information.

Pulse oximetry is a very useful test but it has some drawbacks. It should be trusted after direct comparison to CO-oximetry is done. Abnormal hemoglobin levels (i.e., carboxyhemoglobinemia, methemoglobinemia, and sulfhemoglobinemia) could fool the device. These abnormal levels are detected at the same infrared wavelengths as O_2 and may falsely be interpreted by the oximeter to be oxygen. Impeded blood flow to an area will also affect the pulse oximetry. Correlation with the patient's true pulse will assist in correcting this problem. Light sources may also affect the results; thus the area should be guarded against external light sources.

9. Nutritional studies

Indirect calorimetry is the measurement of oxygen consumption (VO_2) to derive energy expenditure (EE) and

carbon dioxide production (VCO_2), allowing a respiratory quotient (RQ) to be derived. Respiratory quotient obtained from the calorimetry yields the type and amount of substrate used in metabolism (carbohydrate, protein, fats). It is calculated as follows:

$$RQ = VO_2/VCO_2$$

This noninvasive test gives useful information as to the resting energy expenditure (REE), the amount of calories needed for minimal existence expressed in kilocalories per 24 hours. What it measures is the output side of the nutrition question, because the input side is known and measured. The RQ will indicate the type of fuel substrates being metabolized. For example, an RQ of 1.0 indicates carbohydrates; an RQ of 0.80 indicates mixed carbohydrates, fats, and protein; an RQ of 0.75 indicates lipid metabolism; and an RQ of 0.65 could be seen in an individual in ketosis. If the 24-hour urine urea nitrogen value is known, nonprotein R can be calculated along with the actual amount of carbohydrates, fats, and protein metabolized in grams and percent of EE.

10. Body Plethysmography (Body Box)

The body plethysmography method is used to measure the exact amount of air in the thorax. This is accomplished by having the subject sit inside an airtight box and breathe through a flow-measuring device. A panting maneuver is employed, and a shutter is closed to measure pressure at the mouth while a second pressure measures the changes of the box. By measuring the mouth and box pressure, the measurements can be applied to Boyle's law. The thoracic gas volume (TGV), which correlates to functional residual capacity (FRC), can be measured. The compliance of the lungs can be measured, but doing so requires the subject to swallow an esophageal balloon. This device can also measure airway resistances of the lung. Advantages are that the body box measures all air in the thorax, which causes volumes to be larger in box studies than by other methods. Disadvantages to the body box test are that some patients have claustrophobia, and individuals with perforated eardrums will tend to have readings much higher than normal, which could be misleading. Patients with obesity may not be able to be tested because of the weight limitations of the equipment. This test requires total patient cooperation and ability to follow commands.

Purpose

- To differentiate between obstructive or restrictive lung diseases and quantify the degree of disease.
- To establish baseline test results for comparison with future tests.
- To assess pulmonary/respiratory status before surgery.
- To detect the occurrence of pulmonary dysfunction.
- To evaluate the response to drug therapy.
- To determine pulmonary disability for insurance.
- To determine pulmonary status before and after rehabilitation to document outcomes.

Red Blood Cell Indices (MCV, MCH, MCHC, RDW) (Blood), Erythrocyte Indices Reference Values

	Adult	Newborn
RBC count (million/ μL $\times 10^{12}/\text{L}$ [SI units])	Male: 4.6–6.0 Female: 4.0–5.0 4.6–6.0	4.8–7.2 4.8–7.2
MCV (μm^3 [conventional]) or fl [SI units])	80–98 μm^3	96–108 μm^3
MCH (pg [conventional and SI units])	27–31 pg	32–34 pg
MCHC (% or g/dL [conventional] or SI units)	32–36% 0.32–0.36	32–33% 0.32–0.33
RDW (coulter S)	11.5–14.5%	
	Child	
RBC count (million/ μL or $10^{12}/\text{L}$ [SI units])	3.8–5.5 3.8–5.5	
MCV (μm^3 [conventional]) or fl [SI units])	82–92 μm^3	
MCH (pg [conventional and SI units])	27–31 pg	
MCHC (% or g/dL [conventional] or SI units)	32–36% 0.32–0.36	
RDW (coulter S)		

Description

Red blood cell (RBC) indices include the RBC count, RBC size (MCV: mean corpuscular volume), weight (MCH: mean corpuscular hemoglobin), hemoglobin concentration (MCHC: mean corpuscular hemoglobin concentration), and size differences (RDW: RBC distribution width). Other names for RBC indices are *erythrocyte indices* and *corpuscular indices*. To identify the types of anemias, the healthcare provider depends on the following RBC indices:

- **MCV:** MCV indicates the size of RBC: microcytic (small size), normocytic (normal size), and macrocytic (large size). A decreased MCV, or microcyte, might be indicative of iron deficiency anemia and thalassemia. An example of an increased MCV, or macrocytosis, is pernicious anemia and folic acid anemia. The MCV value can be calculated if the RBC count and hematocrit (Hct) are known:

$$\text{MCV} = \frac{\text{Hct} \times 10}{\text{RBC count}}$$

- **MCH:** MCH indicates the weight of hemoglobin in the RBC regardless of the size. In macrocytic anemias, the MCH is elevated, and it is decreased in hypochromic anemia. The MCH is derived by dividing the RBC count into 10 times the hemoglobin (Hb) value:

$$\text{MCH} = \frac{\text{Hb} \times 10}{\text{RBC count}}$$

- **MCHC:** MCHC indicates the hemoglobin concentration per unit volume of RBCs. A decreased MCHC can

indicate a hypochromic anemia. The MCHC can be calculated from MCH and MCV, or from hemoglobin and hematocrit:

$$\text{MCH} = \frac{\text{MCH} \times 100}{\text{MCV}} \text{ OR } \text{MCHC} = \frac{\text{Hb} \times 100}{\text{Hct}}$$

- **RDW:** The RBC distribution width (RDW) is the size (width) differences of RBCs. RDW is the measurement of the width of the size distribution curve on a histogram. It is useful in predicting anemias early, before MCV changes and before signs and symptoms occur. An elevated RDW indicates iron deficiency, folic acid deficiency, and vitamin B₁₂ deficiency anemias. RDW and MCV are used to differentiate among various RBC disorders (see the accompanying *Anemias: RDW and MCV Values table*).

Anemias: RDW and MCV Values		
RBC Disorder	RDW	MCV
Early factor deficiency (iron, folate, vitamin B ₁₂)	High	Normal
Iron deficiency anemia	High	Low
Folic acid deficiency anemia	High	High
Vitamin B ₁₂ deficiency (pernicious anemia)	High	High
Hemolysis (RBC fragmentation)	High	Low
Hemolysis (autoimmune) anemia	High	High
Sickle cell disease	High	Normal
Sickle cell trait	High	Normal

Purpose

- To monitor RBC count.
- To differentiate between the components of RBC indices to determine health problems.

Reticulocyte Count (Blood)

Reference Values

Adult: 0.5–1.5% of all RBCs, 25,000–75,000 μL .

Reticulocyte count = reticulocytes (%) \times RBC count

Child: *Newborn:* 2.5–6.5% of all RBCs. *Infant:* 0.5–3.5% of all RBCs. *Child:* 0.5–2.0% of all RBCs.

Description

The reticulocyte count is an indicator of bone marrow activity. Reticulocytes are immature, nonnucleated red blood cells (RBCs) that are formed in the bone marrow and passed into circulation. Normally, there are a small number of reticulocytes in circulation; however, an increased number (count) indicates RBC production acceleration. An increased count could be due to hemorrhage or hemolysis or to treatment of iron deficiency, vitamin B₁₂ deficiency, or folic acid deficiency anemia. A persistently low count could be suggestive of bone marrow hypofunction or aplastic anemia.

Giving a percentage is not always the most accurate way of reporting the reticulocyte count, especially when the total

B-64 Appendix B Diagnostic Values and Laboratory Tests

RBC (erythrocyte) count is *not* within normal range. Both the RBC count and the reticulocyte count should be reported.

Purpose

- To aid in the diagnosis of anemias.
- To monitor individuals working with radioactive material or receiving radiotherapy.

Retrograde Pyelography (Retrograde Pyelogram)

Description

A retrograde pyelography test may be performed after or in place of intravenous pyelography (IVP). The contrast dye is injected through a catheter into the ureters and the renal pelvis. The visualization of the urinary tract is exceptionally good because the dye is injected directly. Usually this test is done in conjunction with cystoscopy.

Although retrograde pyelograms are not done very frequently today, this test is still performed when there is a suspected nonfunctioning kidney, an unlocated calculus, or an allergy to IV contrast dye. Only a small amount of the dye that is injected directly into the ureters will be absorbed through the membranes.

Purpose

- To view the urinary tract.
- To check for a nonfunctioning kidney.

- To identify kidney stones.
- To aid in determining the cause of kidney problems.

Procedure

- A consent form should be signed.
- The patient should be NPO for 8 hours before the retrograde pyelography. The patient should not be dehydrated before the test.
- Laxatives and cleansing enemas may be ordered prior to the test.
- Baseline vital signs should be recorded.
- Sedatives/tranquilizers and narcotic analgesics are given approximately 1 hour before the test.
- The patient is usually placed in the lithotomy position (feet and legs in stirrups).
- Radiopaque contrast dye is injected through a ureteral catheter into the renal pelvis and x-rays are taken. As the catheter is removed, additional x-rays may be taken.
- This procedure is usually done under local or general anesthesia, and the test takes approximately 1 hour.

Factors Affecting Diagnostic Results

- Barium in the gastrointestinal tract could interfere with good visualization. Barium studies should be done after a retrograde pyelogram.

Nursing Implications with Rationale Retrograde Pyelography

Pretest

- Record baseline vital signs.
- Obtain a patient history of allergies to seafood, iodine, and/or radiopaque dye used in other diagnostic tests.
- Administer laxatives, cleansing enemas, and premedications as prescribed. If the patient is not hospitalized, check that the prescribed orders were completed at home or in another institution. Check that the consent form has been signed before giving premedications.

Patient Teaching

- Explain to the patient that the purpose of the test is to identify kidney stones or to determine the cause of her kidney problems, or give a similar response related to the symptoms.
- Explain the procedure to the patient. Explain to the patient that she will be placed in stirrups. If the patient is having the test done under local anesthesia, tell the patient that she will most likely feel pressure and the urge to urinate with insertion of the cystoscope.
- Inform the patient that there should be little to no pain or discomfort. Tell her that the test takes about 1 hour.
- Inform the patient that food and fluids are restricted for 8 hours before the test. Some healthcare providers may not restrict

water unless the patient is to have general anesthesia. Check for symptoms of dehydration (e.g., dry mouth and mucous membranes, poor skin turgor, decreased urine output, and fast pulse and respirations). Report symptoms to the healthcare provider and record them on the patient's chart.

Posttest

- Monitor vital signs until stable or as ordered.
- Observe for allergic reactions to the contrast dye (e.g., skin rash, urticaria [hives], flushing, dyspnea, and tachycardia).
- Monitor urinary output. Report and record gross hematuria. Blood-tinged urine usually is normal. Report to the healthcare provider if the patient has not voided in 8 hours or the urinary output is less than 200 mL in 8 hours.
- Give an analgesic for discomfort or pain. Report severe pain.
- Observe for signs and symptoms of infection (sepsis; i.e., fever, chills, abdominal pain, tachycardia, and, later, hypotension).
- Be supportive of the patient and family. Answer the patient's questions, or refer them to a urologist or other appropriate healthcare professional.

Rheumatoid Factor (RF), Rheumatoid Arthritis (RA) Factor, RA Latex Fixation (Serum)

Reference Values

Adult: Less than 1:20 titer; less than 1:40 chronic inflammatory disease; 1:20–1:80 positive for rheumatoid arthritis and other conditions; greater than 1:80 positive for rheumatoid arthritis.

Child: Not usually done.

Older Adult: Slightly increased.

Description

The rheumatoid factor (RF) occurs in 53–94% (average 76%) of patients with rheumatoid arthritis. If the test is negative, it should be repeated.

The RF tests can be positive in many of the collagen diseases. The RF tests should not be used for monitoring follow-up or treatment stages of RA, because RF tests often remain positive when clinical remissions have been achieved. It also takes approximately 6 months for a significant elevation of titer. For diagnosing and evaluating RA, the antinuclear antibody (ANA) and the C-reactive protein agglutination tests are frequently used.

Purpose

- To screen for antibodies (IgM, IgG, or IgA) present in patients with possible rheumatoid arthritis.
- To aid in the diagnosis of RA.

Sigmoidoscopy

Normal Findings

Normal mucosa and structure of the rectum and sigmoid colon.

Description

Sigmoidoscopy, using a flexible sigmoidoscope, can be performed in a healthcare provider's office, clinic, or hospital. It may be part of an annual physical examination or may be requested when the patient does not want a colonoscopy.

Purpose

- To examine the anus, rectum, and distal sigmoid colon.
- To detect blood, polyps, or tumors in the sigmoid colon.
- To obtain a tissue culture or secretion for cytologic study.

Procedure

- A consent form should be signed.
- The patient should follow the pretest preparation given by the physician or healthcare provider. The patient is usually allowed a light dinner the night before the test and then NPO afterward. Usually heavy meals, vegetables, and fruits are prohibited within 24 hours of the test.
- No barium studies should be performed within 3 days of the test.

Nursing Implications with Rationale Sigmoidoscopy

Pretest

- Explain the purpose of the sigmoidoscopy to the patient. The test could be a part of the routine physical examination for preventive healthcare, or to determine the cause of symptoms such as bright blood or mucus in stools, constipation, and bowel changes.
- Explain the procedure to the patient.
- Check the chart to determine if the patient has had a barium study. If so, notify the physician.
- Obtain the patient's history with regard to health problems and pregnancy. Caution should be taken with some health problems, such as ulcerative colitis.
- Record baseline vital signs before the test and following the test.
- Allow the patient time to ask questions and express concerns. Refer questions you cannot answer to a physician or to the appropriate health professional.

Patient Teaching

- Inform the patient that the procedure may cause some discomfort but should not cause severe pain. Encourage the patient to breathe deeply and slowly and to relax during the test. Explain that there may be some gas pains if a small amount of air is injected during the procedure for better visualization.

Posttest

- Monitor vital signs as indicated.
- Observe for signs and symptoms of bowel perforation, for example, pain, abdominal distention, and rectal bleeding. These problems rarely occur. Report all symptoms immediately to the physician or healthcare professional.
- Be supportive of the patient and his or her family.

Patient Teaching

- Encourage the patient to rest for several hours or as indicated after the test. This procedure may be done in a physician's office, clinic, or hospital. If the test is done on an outpatient basis, the patient should rest for 1 hour before leaving.

- Fleet enema(s) (hypertonic salt enema[s]) are given the morning of the test. If enemas are contraindicated, then a rectal suppository such as bisacodyl (Dulcolax) may be prescribed. Fecal material must be evacuated before the examination. Preparation with GoLyteLy could be used. Oral cathartics are seldom used, because they may increase fecal flow from the small intestine during the test.
- The patient should assume a Sims (side-lying) position.
- A lubricated flexible endoscope is inserted into the rectum. The patient should be instructed to breathe deeply and slowly. Air may be injected into the bowel to improve visualization.
- Specimens can be obtained during the procedure.
- The procedure takes approximately 15–30 minutes.

Factors Affecting Diagnostic Results

- Barium can decrease the visualization, and so barium studies should be performed a week before the test or afterward.
- Fecal material in the lower colon can decrease visualization.

Sleep Studies, Polysomnography (PSG)

Description

Normal sleep is composed of two phases: four stages of non-rapid-eye-movement (NREM) sleep and rapid-eye-movement (REM) sleep. Both NREM and REM occur cyclically during sleep at approximately 90-minute intervals.

Sleep disorders such as insomnia occur more frequently in women and increase with age. Older adults have a decrease in stages 3 and 4 of NREM sleep and have frequent waking periods. Children have few REM sleep periods and longer periods of stage 3 and 4 NREM sleep. REM sleep periods become longer during the sleep process, and if the person is aroused from REM sleep, he or she may recall a vivid, bizarre dream. Sleepwalking or nightmares occur in children most frequently during NREM sleep. Sleep disorders occur in 75% of psychiatric patients, which also include those patients with anxiety and mood and panic problems.

Causes of sleep disorders include daytime sleepiness, obstructive sleep apnea (OSA; also called sleep disordered breathing), insomnia, nocturnal awakening, and snoring problems. OSA occurs when there is no ventilation for 10 seconds. It may be attributed to oxygen desaturation, cardiac dysrhythmia, or sleep interruption.

Other indications for PSG include individuals having difficulty staying awake during the day and falling asleep at inappropriate times, pregnancy-associated sleep disorders, “short” sleepers (hyposomniac—sleep duration less than 5 hours), and “long” sleepers (hypersomniac—sleep duration greater than 10 hours).

Testing for sleep disorders is performed in a sleep laboratory at night over an 8-hour period of time. The patient is monitored during the night by electrocardiogram (ECG), pulse oximetry to determine heart rate and oxygen saturation, electroencephalogram (EEG), electrooculogram (EOG), electromyogram (EMG), airflow monitoring, and snoring sensor. All of these testing devices may not be indicated.

Purpose

- To determine the cause of a sleep disorder.

Procedure

- A consent form should be signed.
- Keep a sleep log for 1–2 weeks prior to the PSG test.
- Avoid caffeine products, alcohol, sedatives, and naps 1–2 days before testing.
- Omit prescribed medications until the sleep studies are completed, if indicated.
- Sleep studies are scheduled in the sleep laboratory at night, usually from 10 or 11 p.m. until 6 or 7 a.m. (8-hour period of time).

Nursing Implications with Rationale Sleep Study

- Obtain a history from the patient with regard to medications, past stroke, head injury, headaches, seizures.
- Review the sleep log that the patient has given.
- Check vital signs. Note if respiratory distress is present.

Patient Teaching

- Explain to the patient that electrodes will be attached to the head, chest, and legs:
ECG: selected leads attached
EEG: two sets of electrodes to the scalp
EOG: one electrode to canthus eye
EMG: electrodes attached to the leg muscles
Pulse oximeter: attached to the finger to determine heart rate and oxygen saturation.
- Answer patient's questions or refer the questions to other healthcare professionals.

- Attach electrodes for ECG, EEG, and EMG.
- Attach the pulse oximeter.
- Place a commode by the bedside. Electrode leads may inhibit bathroom use.
- Turn off the lights.
- In the morning, have the patient evaluate his or her sleep experience.

Factors Affecting Diagnostic Results

- Defective electrodes or those that become loose or fall off
- Inability to sleep
- Drugs such as sedatives, caffeine taken prior to the test.

Sodium (Na) (Serum)

Reference Values

Adult: 135–145 mEq/L, 135–145 mmol/L (SI units). *Panic Value:* Less than 115 mEq/L.

Child: *Infant:* 134–150 mEq/L. *Child:* 135–145 mEq/L.

Description

Sodium (Na) is the major cation in the body's extracellular fluid (ECF), and it has a water-retaining effect. When the ECF has excess sodium, more water is reabsorbed from the kidneys.

Sodium has many functions. It helps to maintain body fluids, is responsible for conduction of neuromuscular impulses via the sodium pump (sodium shifts into cells as potassium shifts out for cellular activity), is involved in enzyme activity, and regulates acid–base balance by combining with chloride or bicarbonate ions.

The body needs approximately 2–4 g of sodium daily. The American people daily consume approximately 6–12 g (90–240 mEq/L) of sodium in the form of salt (NaCl). A teaspoon of salt contains 2.3 g of sodium.

The names for sodium imbalances are *hyponatremia* (serum sodium deficit) and *hypernatremia* (serum sodium excess). When the serum sodium level is 125 mEq/L, sodium replacement with normal saline (0.9% NaCl) should be considered, and if the serum sodium level is 115 mEq/L or lower, concentrated saline solutions (3% or 5% NaCl) might be ordered. When rapidly replacing sodium loss, assessment for overhydration is important.

Purpose

- To monitor the sodium level.
- To detect sodium imbalance.
- To compare the sodium level with levels of other electrolytes.

Sodium (Na) (Urine)

Reference Values

Adult: 40–220 mEq/L per 24 hours.

Child: Similar to adult.

Description

Sodium excretion varies according to the sodium intake, aldosterone secretion, urine volume, and disease entities, such as chronic renal failure, adrenal gland dysfunction (Addison disease and Cushing syndrome), cirrhosis of the liver, and heart failure.

When the urine sodium level is less than 40 mEq/L per 24 hours, the decreased sodium excretion could be due to sodium retention or decreased sodium intake. The body could be retaining sodium even with a low serum sodium level.

The urine sodium level should be monitored when edema is present and the serum sodium level is low or normal.

Purpose

- See Sodium (serum).

Stress/Exercise Tests: Treadmill Exercise Electrocardiology, Exercise Myocardial Perfusion Imaging Test (Thallium/Technetium Stress Test), Nuclear Persantine (Dipyridamole) Stress Test, Nuclear Dobutamine Stress Test

Normal Findings

Normal electrocardiogram (ECG) with little or no ST-segment depression with exercise. Normal myocardial perfusion.

Description

Treadmill stress testing is based on the theory that patients with coronary artery disease (CAD) will have marked ST-segment depression on the ECG when exercising. Depression of the ST segment and depression or inversion of the T

wave indicate myocardial ischemia. ST-segment depression usually occurs before the onset of pain and is still present for some time after the pain subsides. Mild ST-segment depression after exercise can occur without CAD.

Treadmill and Bicycle Electrocardiology

During the treadmill stress test, the work rate (load) is changed every 3 minutes by increasing the speed slightly and the degree of incline (grade) by 3% each time (3%, 6%, 9%). Patients will exercise until they are fatigued, develop symptoms, or reach their maximum predicted heart rate (MPHR).

Exercise Thallium Perfusion Test

The radioisotope thallium-201, which accumulates in the myocardial cells, is used during the stress test to determine myocardial perfusion during exercise. With severe narrowing of the coronary arteries, less thallium accumulates in the heart muscle. If a coronary vessel is completely occluded, no uptake of thallium will occur at the myocardial area that the vessel supplies. The presence of thallium is most effective for assessing myocardial viability.

Patients with CAD may have normal thallium perfusion scans at rest; however, during exercise, when the heart demands more oxygen, myocardial perfusion decreases. The patient returns in 2 or more hours to take a second scan of the heart at rest. Frequently second scans are done to differentiate between an ischemic area and an infarcted or scarred area of the myocardium. In the resting state, blood flow in a coronary artery with stenosis remains normal until the stenosis exceeds 85%.

Exercise Technetium Perfusion Test

For detection of myocardial ischemia, technetium Tc-99m-laced compounds, such as Tc-99m-sestamibi (Cardiolite), are commonly used for perfusion scanning because they are trapped in the myocardium and do not redistribute. Technetium compounds provide more clinical information by allowing the assessment of perfusion, wall motion, and ejection fraction in one test procedure. Other technetium agents approved by the U.S. Food and Drug Administration are Tc-99m-teboroxime and Tc-99m-tetrofosmin.

Cardiolite imaging is perhaps the most useful noninvasive test for diagnosing and following CAD at the present time. Positive stress Cardiolite scanning should be considered strong presumptive evidence of CAD. The more markedly abnormal the scan, the more likely it is that the patient has serious CAD. It is important to correlate the scan findings with the ECG, the exercise stress test, and the patient's symptoms. The use of gated single positron emission (SPECT) (gated refers to the synchronizing of images with the computer and the patient's heart rhythm) greatly improves the sensitivity and specificity of the Cardiolite scan.

Nuclear Persantine (Dipyridamole) Stress Test

This is an alternative stress test usually ordered when the patient is not physically able to exercise or to walk on a treadmill. Persantine is administered intravenously to dilate the coronary arteries and increase blood flow to the myocardium. Arteries that have become narrowed because of CAD cannot expand like normal arteries. Thallium, Cardiolite, or

B-68 Appendix B Diagnostic Values and Laboratory Tests

other Tc-based compounds, administered intravenously, detect decreased blood flow to the heart muscle (myocardium). The isotope is administered 3 minutes after the 4-minute IV Persantine infusion.

The patient must avoid foods, beverages, and medications containing xanthines (e.g., caffeine), such as colas, chocolate, and tea, 24 hours prior to the test. Theophylline preparations should be discontinued 36–48 hours prior to the test.

Nuclear Persantine stress testing is contraindicated for patients who have severe bronchospastic lung disease, such as asthma, or advanced atrioventricular heart block. Additional unfavorable conditions in which this test is not indicated include acute myocardial infarction within 48 hours of the test, severe aortic or mitral stenosis, resting systolic blood pressure less than 90 mmHg, and allergy to dipyridamole.

Nuclear Dobutamine Stress Test

Dobutamine is an adrenergic (sympathomimetic) drug that increases myocardial contractility, heart rate, and systolic blood pressure, which increases the myocardial oxygen consumption and thus increases coronary blood flow. If the patient has heart block or asthma and takes a theophylline preparation daily, this test may be ordered instead of the nuclear Persantine (dipyridamole) stress test. Dobutamine is an alternative stressor test.

Nuclear dobutamine stress testing can identify patients with CAD and identify those who are at high risk for severe ischemic changes prior to vascular surgery.

Contraindications for nuclear dobutamine stress testing include patients who have had an acute myocardial infarction within 10 days, acute myocarditis or pericarditis, unstable angina pectoris (prolonged episodes, episodes at rest), ventricular or atrial dysrhythmias, severe hypertension or hypotension, severe aortic or mitral stenosis, hyperthyroidism, and acutely severe infections. Propranolol (Inderal) should be available for any possible adverse reaction to the dobutamine infusion.

Purpose

- To screen for CAD.
- To evaluate myocardial perfusion.
- To differentiate between an ischemic area and an infarcted or scar area of the myocardium.
- To develop a cardiac rehabilitation program.
- To evaluate the work capacity of cardiac patients.
- To evaluate drug efficacy.

Procedure

- A consent form should be signed by the patient.
- The patient should be NPO 2 or 3 hours before the test. The patient should not consume alcohol or caffeine-containing drinks and should avoid smoking for 2–3 hours before the test. Milk could cause nausea.
- Medications should be taken, unless otherwise indicated by the healthcare provider.
- Comfortable clothes should be worn (i.e., shorts or slacks with a belt and sneakers or tennis shoes with socks). Most bedroom slippers are not suitable.

- The chest is shaved as needed, and the skin is cleansed with alcohol.
- Electrodes are applied to the chest according to the lead selections.
- Baseline ECG, pulse rate, and BP are taken and then monitored throughout the test.
- The test is stopped if the patient becomes dyspneic, suffers severe fatigue, complains of chest pain, has a rapid increase in pulse rates and/or BP, or develops life-threatening arrhythmias (i.e., ventricular tachycardia, premature ventricular contractions [PVCs] greater than 10 PVC in 1 minute).
- Usually the test is not stopped abruptly unless necessary. Vital signs and ECG tracings are recorded at the end of the testing or the recovery stage.
- The test takes approximately 30 minutes, which includes up to 10–15 minutes of exercising.

Treadmill Stress Test

Usually there are five stages. In the first stage the speed is 2 mph at a 3% grade or incline for 3 minutes. In the second stage the speed is 3.3 mph at a 6% grade for another 3 minutes. Normally the speed does not go beyond 3.3 mph. With each stage the grade is increased 3% and the time is increased by 3 minutes, unless fatigue or adverse reactions occur. The power-driven treadmill has support rails to help the patient maintain balance.

Bicycle Ergometer Test

The patient is instructed to pedal the bike against an increased amount of resistance. The bike handlebars are for maintaining balance and should not be gripped tightly for support. The patient should not shower or take a hot bath for 2 hours after testing.

Exercise Thallium Perfusion Test

An IV line is inserted. Exercise time for the stress test is determined. The patient attains the maximal exercise level, and thallium is injected intravenously 1 minute before the test ends. The patient continues to exercise for 1–2 more minutes. A scan is then taken by gamma camera, which visualizes thallium perfusion of the myocardium.

Patient returns in 2 or more hours for a second scan.

Exercise Technetium Perfusion Test

With the Cardiolite stress test, the patient receives two injections intravenously, one at rest and one at stress. The patient should be NPO for 2–3 hours prior to the test. Any medications that may affect the blood pressure or heart rate should be discontinued 24–48 hours prior to the test (unless the test is being performed to evaluate the efficacy of cardiac medications). The patient should be physically able to exercise on a treadmill. The total time for the test is 3 hours, which is shorter than the time required for thallium imaging.

Persantine (Dipyridamole) Stress Test

The patient remains NPO after midnight except for water. Patients with diabetes may have a light breakfast of juice and toast and one half of their insulin dose, but should first

Nursing Implications with Rationale

Stress/Exercise Tests

Pretest

- Recognize when the stress/exercise test is contraindicated (i.e., with recent myocardial infarction; severe, unstable angina; uncontrolled cardiac dysrhythmias; heart failure; or recent pulmonary embolism).
- Check that the consent form has been signed.
- Recognize whether a treadmill stress test or pharmacologic stress test is appropriate.
- Review medications that may interfere with test, for example, beta-blockers to decrease heart rate.

Patient Teaching Treadmill Stress Test

- Explain the procedure to the patient with regard to being NPO 2–3 hours prior to the test; not smoking; continuing with medications; the clothing and shoes that should be worn; shaving and cleansing the chest area; electrode application; continuous monitoring of the ECG, pulse rate, and BP; and not leaning on the rails of the treadmill or the handlebars of the bike.
- Instruct the patient to inform the cardiologist or technician if he experiences chest pain, difficulty in breathing, or severe fatigue. The risk of having a myocardial infarction during the stress test is less than 0.2%.
- Inform the patient that after 10–15 minutes of testing or when the heart rate is at a desired or an elevated rate, the test is stopped. It will be terminated immediately if there are any severe ECG changes (i.e., multiple PVCs, ventricular tachycardia).
- Allow the patient to ask questions. Refer questions you cannot answer to other appropriate health professionals (i.e., a cardiologist, a specialized technician, or a nurse in the stress test laboratory).
- Instruct the patient to continue the walking exercise at the completion of the test for 2–3 minutes to prevent dizziness. The treadmill speed will be decreased. Tell the patient that he may be perspiring and may be “out of breath.” Profuse diaphoresis, cold and clammy skin, severe dyspnea, and severe tachycardia are not normal; if they occur, the test will be terminated.
- Inform the patient that an ECG and vital signs are taken 5–10 minutes after the stress test (recovery stage) until returning to baseline.
- Encourage the patient to participate in a cardiac/exercise rehabilitation program as advised by the healthcare provider/cardiologist. Tell the patient of the health advantages: constant heart monitoring, improved collateral circulation, increased oxygen supply to the heart, and dilation of the coronary resistance vessels.
- Discourage the patient over 35 years of age from doing strenuous exercises without having a stress/exercise test or a cardiac evaluation.
- Inform the patient that he can resume activity as indicated.
- Explain to the patient that a written report is submitted to the patient's personal physician from the cardiologist. The patient should check with the healthcare provider for the test results.

Exercise Thallium Perfusion Test—Patient Teaching

- Explain the procedure for the test (*see Procedure*). Explain that the difference between the routine stress test and the exercise thallium perfusion test is an injection of thallium 201 during the routine stress test followed by scans and/or x-rays. Nursing implications are the same for both tests.
- Instruct the patient to return for additional pictures in 2–4 hours as indicated by the technician or cardiologist.

Exercise Technetium Perfusion Test

- Explain the procedure (*see Procedure*).
- The patient should lie quietly for approximately 30 minutes during the imaging.
- Inform the patient that the test should last no more than 3 hours.
- Instruct the patient taking medications that affect the blood pressure or heart rate to check with the healthcare provider about discontinuing the medications for 24–48 hours prior to testing.

Nuclear Persantine (Dipyridamole) Stress Test

- Explain the procedure for the test to the patient (*see Procedure*). The patient should be NPO after midnight except for water.
- Instruct the patient to avoid food, beverages, and drugs that contain caffeine. Beverages and foods rich in caffeine include colas (Coke and Pepsi), Dr. Pepper, Mountain Dew, Tab, chocolate (syrup and candy), tea, and coffee. Decaffeinated coffee and tea should also be avoided. Drugs containing caffeine include Anacin, Excedrin, NoDoz, Wigraine, Darvon compound, Cafergot, and Fiorinal. Theophylline preparations should be avoided 36 hours before the test; the patient should check with the healthcare provider in case it is not possible to discontinue the theophylline drug for that period of time.
- Explain to the patient that first Persantine will be given intravenously and then an isotope. The patient is positioned under a camera with his or her left arm over the head. The camera will be moving very close to the chest for taking pictures (imaging). The imaging takes approximately 20–30 minutes.
- Instruct the patient to return for additional pictures in 2–4 hours as indicated by the technician or cardiologist.
- Explain to the patient that a written report is submitted to the patient's personal healthcare provider from the cardiologist.

Nuclear Dobutamine Stress Test

- Explain the procedure for the test to the patient (*see Procedure*). The patient should be NPO after midnight except for water.
- Instruct the patient to discontinue beta-blockers, calcium-channel blockers, or ACE inhibitors for 36 hours prior to the test with the healthcare provider's approval. Give the patient the date and time for stopping the drug. Nitrates should not be taken for 6 hours before the test unless necessary (check with the healthcare provider).
- Inform patients of side effects that may occur, such as chest pain, palpitations, headache, paresthesia, nausea, tremor, ventricular arrhythmias, ST-segment depression, and hypotension, which resolves with the discontinuation of the infusion.

check with the healthcare provider. Caffeine-containing drugs, food, and beverages such as colas must be avoided 24 hours prior to the test. Decaffeinated beverages should also be avoided. Theophylline preparations (Theo-Dur, Theolair-SR, Bronkodyl, Elixophyllin SR, and others) should be stopped 36 hours before the test.

The patient is in a supine position during the test. The patient receives a total of 0.56 mg/kg per dose of IV Persantine (dipyridamole) over a period of 4 minutes. Three minutes after the Persantine infusion, the isotope (thallium, Cardiolite, or other Tc-based compound) is injected intravenously. Aminophylline should be available to reverse any adverse reaction to Persantine. The imaging procedure begins 15–30 minutes after the isotope infusion. Heart rate, blood pressure, and ECG will be monitored before and during the test.

The test is terminated if any of the following occur: ventricular tachycardia, second-degree heart block, severe ST-segment depression, severe hypotension (less than 90 mmHg), or severe wheezing. The patient with asthma may use a beta-agonist inhaler if necessary during the procedure.

Nuclear Dobutamine Stress Test

The patient remains NPO after midnight except for water. Beta-blockers, calcium-channel blockers, and angiotensin-converting enzyme (ACE) inhibitors should be discontinued 24 hours prior to the test. Nitrates should not be taken 4–6 hours before the test. Dobutamine is administered intravenously using an infusion pump. The dobutamine is mixed in a liter of normal saline solution and the dose and infusion rate are increased until the patient's heart rate reaches approximately 85% of his or her maximum predicted heart rate. If the heart rate is less than 110 bpm, IV atropine sulfate may be given. The isotope is injected when the maximum heart rate is achieved.

The test is terminated if any of the following occur: atrial or ventricular tachycardia, atrial flutter or fibrillation, severe ST-segment depression, progressive anginal pain, severe hypotension (less than 90 mmHg systolic), or severe hypertension (greater than 220 mmHg systolic or greater than 120 mmHg diastolic). Nitroglycerin may be given for angina pain. Propranolol (Inderal) should be available for adverse reaction to dobutamine. The imaging procedure occurs 15 minutes after the completion of the dobutamine infusion.

Factors Affecting Diagnostic Results

- Certain drugs (e.g., digitalis preparations) that can cause a false-positive test result.
- Leaning on support rails of the treadmill or the handlebars of the bicycle.

Nuclear Persantine (Dipyridamole) Stress Test

- Taking theophylline preparations within 24 hours of the test.
- Ingesting caffeine products (beverages, chocolates) 6 hours before the test.
- Ingesting decaffeinated beverages 4 hours before the test.

Nuclear Dobutamine Stress Test

- Taking beta-blockers, calcium-channel blockers, or ACE inhibitors 24 hours before the test.

- Taking nitrates 4 hours before the test.
- Ingesting a full meal 4 hours before the test.

Theophylline (Serum), Aminophylline, Theo-Dur, Theolair, Slo-Phyllin, Elixophyllin, Sustaire

Reference Values

Therapeutic Range: *Adult*: 5–20 mcg/mL, 28–112 µmol/L (SI units).

Older Adult: 5–18 mcg/mL. *Premature Infant*: 7–14 mcg/mL. *Neonate*: 3–12 mcg/mL. *Child*: Same as adult.

Toxic Level: *Adult*: Greater than 20 mcg/mL, greater than 112 µmol/L (SI units). *Older Adult*: Same as adult. *Premature Infant*: Greater than 14 mcg/mL. *Neonate*: Greater than 13 mcg/mL. *Child*: Same as adult.

Description

Theophylline, a xanthine derivative, relaxes smooth muscle of the bronchi and pulmonary blood vessels; reduces pulmonary hypertension; stimulates the central nervous system; stimulates myocardium, resulting in an increase in the force of contraction and cardiac output; increases renal blood flow, causing diuresis; and relaxes smooth muscles of the gastrointestinal tract. Usually theophylline products are given to control asthmatic attacks and to treat acute attack. Oral theophylline preparations are well absorbed from the gastrointestinal tract.

Ninety percent of theophylline is metabolized in the liver, with about 60% bound to plasma protein and 40% free. Ten percent of the drug is excreted unchanged in the urine. The half-life of theophylline is 5–10 hours in a nonsmoker, 3.5–5 hours in a smoker, and 3.5 hours in children. Peak blood levels after an orally administered dose of theophylline occur in 1–2 hours.

Individuals with heart failure or liver disease or who are either very young or older can develop theophylline toxicity quickly. Serum theophylline levels in these individuals should be monitored frequently.

Early signs and symptoms of theophylline toxicity are anorexia, nausea, vomiting, abdominal discomfort, nervousness, jitters, tachycardia, and cardiac arrhythmias. If severe theophylline toxicity occurs (greater than 30 mcg/mL), cardiac dysrhythmias, seizures, respiratory arrest, and/or cardiac arrest might result.

Purpose

- To monitor theophylline levels.

Thyroid-Stimulating Hormone (TSH) (Serum)

Reference Values

Values differ according to the laboratory method used.

Adult: 0.35–5.5 micro-international unit/mL, (µIU/mL), less than 3 ng/mL.

Newborn: Less than 25 micro-international unit/mL (µIU/mL) by the third day.

Description

The anterior pituitary gland (anterior hypophysis) secretes thyroid-stimulating hormone (TSH) in response to thyroid-releasing hormone (TRH) from the hypothalamus. TSH stimulates the secretion of thyroxine (T_4) produced in the thyroid gland. The secretion of TSH is dependent on the negative-feedback system: A decreased T_4 level promotes the release of TRH, which stimulates TSH secretion. An elevated T_4 level suppresses TRH release, which suppresses TSH secretion.

TSH and T_4 levels are frequently measured to differentiate pituitary from thyroid dysfunctions. A decreased T_4 level and a normal or elevated TSH level can indicate a thyroid disorder. A decreased T_4 level with a decreased TSH level can indicate a pituitary disorder.

Purpose

- To suggest hypothyroidism due to pituitary involvement.
- To compare test results with T_4 level to differentiate between pituitary and thyroid dysfunction.

Thyroxine (T_4) (Serum)

Reference Values

Adult: *Reported as Serum Thyroxine:* T_4 by column: 4.5–11.5 mcg/dL. T_4 (RIA): 5–12 mcg/dL. Free T_4 : 1.0–2.3 ng/dL. *Reported as Thyroxine Iodine:* T_4 by column: 3.2–7.2 mcg/dL.

Child: *Newborn:* 11–23 mcg/dL. *1–4 Months:* 7.5–16.5 mcg/dL. *4–12 Months:* 5.5–14.5 mcg/dL. *1–6 Years:* 5.5–13.5 mcg/dL. *6–10 Years:* 5–12.5 mcg/dL.

Description

Thyroxine (T_4) is the major hormone secreted by the thyroid gland and is at least 25 times more concentrated than triiodothyronine (T_3).

In some institutions the T_4 test is required for all newborns (as is the phenylketonuria [PKU] test) to detect a decreased thyroxine secretion, which could lead to irreversible intellectual disability.

Purpose

- To determine thyroid function.
- To aid in the diagnosis of hypo- or hyperthyroidism.
- To compare test results with other laboratory thyroid tests.

Torch Screen Test, Torch Battery, Torch Titer

Reference Values

Maternal: *IgG Titer Antibodies:* Negative. *IgM Titer Antibodies:* Negative.

Infant: Same as maternal; infant should be under 2 months of age.

Description

TORCH stands for toxoplasmosis, rubella, cytomegalovirus (CMV), and herpes simplex. During pregnancy, TORCH infections can cross the placenta and can result in mild or

severe congenital malformation, abortion, or stillbirth. The severe effect from these organisms occurs during the first trimester of pregnancy. Prenatally, the TORCH screening test is performed only when a TORCH infection is suspected, such as rubella infection.

The TORCH screening test is more frequently performed when congenital infection in the infant is suspected. The IgG titers are compared with both mother's and infant's serum. If the IgG titer level is higher in the infant than the mother and the IgM titer is present in the infant, congenital TORCH infection is likely. This test might be repeated in several weeks. Individual testing might be necessary along with clinical information to identify the TORCH infection. Rubella and CMV are the most common.

Purpose

- To detect TORCH infections in newborns and mothers.

Triglycerides (Serum)

Reference Values

Adult: *12–29 Years:* 10–140 mg/dL. *30–39 Years:* 20–150 mg/dL. *40–49 Years:* 30–160 mg/dL. *Greater Than 50 Years:* 40–190 mg/dL. 0.44–2.09 mmol/L (SI units).

Child: *Infant:* 5–40 mg/dL. *5–11 Years:* 10–135 mg/dL.

Risk Values of Cardiovascular Disease: *Low Risk:* Less than 100 mg/dL. *Normal Risk:* 149 mg/dL. *Borderline High Risk:* 150–199 mg/dL. *High Risk:* 200–499 mg/dL. *Very High Risk:* Greater than 500 mg/dL.

Description

Triglycerides, blood lipids formed by esterification of glycerol and three fatty acids, are carried by the serum lipoproteins. The intestine processes the triglycerides from dietary fatty acids (exogenous), and they are transported in the bloodstream as chylomicrons (tiny fat droplets covered by protein), which gives the serum a milky or creamy appearance after a meal rich in fats. The liver is also responsible for manufacturing triglycerides, but these do not travel as chylomicrons. The majority of triglycerides are stored as lipids in the adipose tissue. A function of triglycerides is to provide energy to the heart and skeletal muscles.

Triglycerides are a major contributor to arterial diseases and are frequently compared with cholesterol by the lipoprotein electrophoresis. As the concentration of triglycerides increases, the very-low-density lipoproteins (VLDL) also increase, leading to hyperlipoproteinemia.

Individuals who are at highest risk of elevated triglyceride levels are those who drink alcohol, are obese, consume foods high in simple sugars, take certain medications (thiazides, hormone therapy), have a familial history of high triglycerides, and have medical conditions such as type 2 diabetes mellitus, hypothyroidism, and cardiac, kidney, or liver disease. The statin drugs for lowering cholesterol have less effect on lowering the triglycerides.

Purpose

- To monitor triglyceride levels.
- To compare test results with lipoprotein groups (VLDL) that indicate hyperlipidemia.

Triiodothyronine (T₃) (Serum)

T₃ RIA

Reference Values

Adult: 80–200 ng/dL.

Child: *Newborn*: 40–215 ng/dL. *5–10 Years*: 95–240 ng/dL.

10–15 Years: 80–210 ng/dL.

Description

Triiodothyronine (T₃), one of the thyroid hormones, is present in small amounts in blood and is more short acting and more potent than thyroxine (T₄). Both T₃ and T₄ have similar actions in the body. Serum T₃ is secreted in response to thyroid-stimulating hormone (TSH) from the pituitary gland and thyroid-releasing hormone (TRH) from the hypothalamus and is measured directly by radioimmunoassay (RIA).

Serum T₃ RIA measures both bound and free T₃. It is effective for diagnosing hyperthyroidism, especially T₃ thyrotoxicosis, in which T₃ is increased and T₄ is in normal range. It is not as reliable for diagnosing hypothyroidism, because T₃ remains in normal range. T₃ RIA and T₃ update are two different tests.

Purpose

- To aid in the diagnosis of hyperthyroidism.
- To compare T₃ with T₄ for determining a thyroid disorder.

Troponins (Serum, Blood)

Cardiac-Specific Troponin 1 (cTnI), Cardiac-Specific Troponin T (cTnT)

Reference Values

Cardiac Troponin 1: 0.1–0.5 ng/mL, 0.1–0.5 mcg/L (SI units). Suspicious myocardium injury: 0.5–2.0 ng/mL. Positive myocardium injury: Greater than 2.0 ng/mL, greater than 2.0 mcg/L (SI units).

Cardiac Troponin T: Less than 0.2 ng/mL, less than 0.2 mcg/L (SI units).

Description

Troponins are biochemical markers for cardiac diseases, especially for the diagnosis of acute myocardial infarction (AMI). The troponins are proteins, present in both the heart muscle and skeletal muscles; the enzyme-linked immunosorbent assay (ELISA) test can separate which muscle is involved. Cardiac-specific troponin 1 (CTnI) and cardiac-specific troponin (cTnT) are released from the heart into the bloodstream 1–3 hours after the onset of symptoms of AMI. Thrombolytic treatment (clot busters) could be available for early onset of AMI. The troponins are also useful in detecting silent myocardial infarction and microinfarctions accompanied by chest pain. The electrocardiogram may not have changed.

Troponins are more specific for cardiac muscle injury than creatine phosphokinase MB (CPK-MB). CPK-MB can be elevated with severe skeletal muscle injury. The cardiac troponins are usually within normal range in noncardiac muscle diseases.

Following the infarction, the cTnI remains elevated for 5–9 days and the cTnT remains elevated for 10–14 days. A new qualitative immunoassay test for troponins may be performed at the bedside. The new test takes about 20 minutes and is read much like a glucometer.

Purpose

- To differentiate between cardiac and noncardiac chest pain.
- To evaluate patients with unstable angina pectoris with myocardial damage.
- To assist in the diagnosis of acute myocardial infarction.

Ultrasonography

Normal Findings

A normal pattern image of the organ or normal Doppler analysis.

Description

Ultrasonography (ultrasound or sonogram) is a diagnostic procedure used to visualize body tissue structure or waveform analysis of Doppler studies. An ultrasound probe called a transducer is held over the skin surface or in a body cavity to produce an ultrasound beam in the tissues. The reflected sound waves or echoes from the tissues can be transformed by a computer into scans, graphs, or audible sounds (Doppler).

The ultrasonography diagnostic test, a dynamic, non-ionizing test, is relatively inexpensive and fast, and it does not cause any known harm to the patient. It is also referred to as a *sonogram*. It has limitations in that it cannot be used to determine bone abnormalities or for air-filled organs. The ultrasound beam cannot penetrate air. In individuals with obesity it is difficult for sound waves to pass through fat layers. Ultrasound is particularly useful in children because of their small size, and it does not require ionizing radiation.

Ultrasound can detect tissue abnormalities (i.e., masses, cysts, edema, stones). Most ultrasound studies (e.g., gallstones) do not need other modalities for confirmation; however, computed tomography, magnetic resonance imaging, or radionuclide scanning may be used to confirm certain ultrasound results.

Some of the body structures that this procedure examines are the abdominal aorta, arteries and veins (Doppler), brain, breast, carotid artery, eye and eye orbit, gallbladder and bile ducts, heart, kidney, liver, pregnant uterus (pelvic), pancreas, prostate, scrotum/testes, spleen, lungs, and thyroid.

Abdominal Aorta

The area for abdominal scanning includes the xiphoid process to the umbilicus. Ultrasonography can detect aortic aneurysms with 98% accuracy and determine whether they are fusiform, saccular, or dissecting types.

Arteries and Veins with Doppler

An arterial study is indicated for patients with symptoms of claudication, rest pain, or a persistent open wound in the

lower extremity. Doppler ultrasonography can determine the presence or absence of flow, flow direction, and flow character. The Doppler effect can detect decreased blood flow caused by partial arterial occlusion or by deep venous thrombosis. It can be used in fetal monitoring during labor and delivery. The Doppler instrument is available to nurses for monitoring blood flow for those who have altered circulation. Low-frequency waves usually indicate low-velocity blood flow. This procedure may also be used to evaluate the patency of a graft.

Brain

Echoencephalography is an ultrasound of the brain. Neonatal neurosonography is also an ultrasound of the brain. If the ventricles are dilated and/or shifted to one side, then pathologic findings, such as intracranial lesions or intracranial hemorrhage, may be suspected. This test is most useful for evaluating hydrocephalus and intracranial hemorrhage in newborns.

Breast

Ultrasonography of the breast is helpful for (1) diagnosing breast lesions in women who have dense breasts, (2) differentiating between cystic and solid lesions, (3) follow-up of patients with fibrocystic breast disease, and (4) evaluating women with silicone breast implants for breast lesions. Breast ultrasonography may be suggested for pregnant women as well as any woman with a palpable breast mass. X-ray mammography remains the *screening* examination of choice, however, because ultrasonography cannot detect microcalcification. Still, ultrasonography serves as a valuable adjunctive tool.

Carotid Artery with Doppler

Blood flow in the carotid artery can be measured by using the Doppler technique to determine carotid stenosis. During a carotid sonogram, vertebral arteries can be visualized by this Doppler technique to determine antegrade or retrograde blood flow through these vessels.

Eye and Eye Orbit

Ultrasonography of the eye and eye orbital area may be used to (1) determine abnormal tissue of the eye (vitreous adhesions, retinal detachment) when opacities within the eye are present and (2) detect orbital lesions. With this test, orbital lesions can be distinguished from orbital inflammation.

Gallbladder and Bile Ducts

Gallbladder ultrasonography is accurate in delineating the anatomy of the gallbladder and biliary system. It can evaluate the size, structure, and position of the gallbladder and can determine the presence of gallstones. It may be used in conjunction with nuclear medicine.

Heart (Cardiac)

Echocardiography is ultrasound of the heart. It can determine the size, shape, and position of the heart and the movement of heart valves and chambers. The methods commonly used are the M-mode method, which records the motion of the intracardiac structures, such as valves, and the two-dimensional method, which records a cross-sectional view

of cardiac structures. The echocardiogram is useful in detecting mitral stenosis, pericardial effusion, congenital heart disease, and enlargement of a heart chamber. (*See the Echocardiography discussion for detailed data.*)

Intravascular Ultrasonography

An ultrasound transducer mounted on a catheter is used to assess pathologic changes to the arterial wall and to evaluate vascular procedures such as angioplasty placement. This test is usually performed in large medical centers.

Kidneys (Renal)

Ultrasonography is a reliable method of identifying and differentiating renal cysts and tumors. Cysts are echo free, and tumors and renal calculi record multiple echoes. This test is highly recommended when the patient is hypersensitive to the iodinated contrast dye used in x-ray tests (e.g., CT, intravenous pyelography). This test is most useful for depicting anatomic changes in the kidneys.

Liver (Hepatic)

The liver was one of the first organs examined by ultrasound, because it is large and difficult to x-ray. Ultrasonography is useful for distinguishing between cysts and tumors and for determining the size, structure, and position of the liver. With cysts, the sonogram reflects an echo-free response, whereas with a tumor, multiple echoes are recorded. Ultrasonography is very helpful in differentiating obstructive from nonobstructive jaundice. The patient may have abnormal liver laboratory values, and the liver may still appear within normal limits.

Pelvis

Uterus: Ultrasonography may be used to distinguish between cystic, solid, and complex masses as well as to localize free fluid and inflammatory processes. *Ovaries:* The dimensions of the ovaries, as well as ovarian cysts and solid lesions, can be identified by pelvic sonography. Pelvic ultrasonography is a valuable tool but should not replace a gynecologic examination. *Pregnancy:* In pregnancy, the amniotic fluid enhances reflection of sound waves from the placenta and fetus, thus revealing their size, shape, and position. Echoes from the pregnancy may be seen after as few as 4 weeks of amenorrhea. For visualization of pelvic structures, a full bladder is indicated in the nongravid and first-trimester pregnancy. The uterus is sometimes evaluated with a transvaginal transducer with the bladder empty.

Pancreas

The pancreas is a difficult organ to examine and may require distending the stomach with water to create an acoustic window. Ultrasonography does not measure pancreatic function, but it can determine overall size of the gland and detect pancreatic abnormalities, such as pancreatic tumors, pseudocysts, and pancreatitis. This test is useful for patients who are too thin for adequate CT scanning.

Prostate (Transrectal)

Ultrasonography of the prostate gland is used to (1) evaluate palpable prostate nodules and seminal vesicles, (2) determine

Nursing Implications with Rationale

Ultrasonography

- Obtain a signed consent if needed.
- The patient should be NPO for 6 hours prior to all abdominal studies (gallbladder, aorta, and so on).
- Confirm that the patient has not had any other tests that may interfere with test results, such as having an upper GI series.

Patient Teaching

- Explain the purpose and procedure to the patient (see *Description and Procedure above*). Tell the patient that an oil or lubricant is applied to the skin surface at the site of the organ and that a probe will move with light pressure back and forth over the area.
- Inform the patient that this is a painless procedure unless there has been trauma (injury) to the area. Tell the patient that there will be no exposure to radiation, and that the ultrasound test is considered to be safe and fast.
- Instruct the patient to remain still during the procedure. Inform him or her that the test usually takes 30 minutes or less, except

for a few ultrasound tests (e.g., arterial, venous, and carotid ultrasonography), which could take 1 hour.

- Encourage the patient to ask questions and to express any concerns. Refer questions you cannot answer to the ultrasonographer or the healthcare provider.
- Be supportive of the patient and the family.

Eye

- Avoid rubbing the eyes until the anesthetic effect has worn off in order to avoid corneal abrasion.
- Inform the patient that blurred vision may be present for a short time until the anesthetic has worn off.

Abdominal Studies

- Inform the patient that she or he should be NPO for 6 hours prior to all abdominal studies.
- Confirm that the patient has not had other tests that may interfere with the ultrasonography, such as upper GI series.

if urinary problems may be related to benign prostatic hypertrophy (BPH), (3) detect early small prostatic tumors, and (4) identify tumor location for biopsy and/or radiation purposes. A rectal examination and a prostate-specific antigen (PSA) laboratory test should be included for diagnosing prostatic lesions.

Scrotum/Testes

Ultrasonography of the scrotum sac contents is helpful in diagnosing abscesses, cysts, hydroceles, spermatoceles, varicoceles, testicular tumors, torsion, and chronic scrotal swelling. Pulsed Doppler or color Doppler techniques may be used to assess testicular blood flow.

Spleen

Ultrasonography can be used for determining the size, structure, and position of the spleen. This procedure can identify splenic masses. In some cases it is a useful tool for evaluating the need for splenectomy and for follow-up of pathologies such as hematoma or abscess.

Thoracic (Lungs)

Ultrasonography is useful in identifying lesions, but it is not diagnostic in the air-filled lungs unless there is a lesion, outside the lungs, adherent to the chest wall. It may be used to identify pleural fluid, malposition of the diaphragm, and the presence of an abscess. Ultrasound of the thoracic area may be used in combination with x-ray and thoracic scans.

Thyroid

Ultrasonography of the thyroid is 85% accurate in determining the size and structure of the thyroid gland. This procedure can differentiate between a cyst and a tumor and can determine the depth and dimension of thyroid nodules. Nuclear imaging is the test of choice for thyroid pathology.

Purpose

- To evaluate the size, structure, and position of body organs.
- To evaluate the blood flow in arteries and veins.
- To detect cysts, tumors, and calculi.

Procedure

- Obtain a signed consent form, if necessary.
- Restrict food and fluids for 4–8 hours before abdominal aorta, gallbladder, liver, spleen, and pancreas ultrasound studies.
- The patient should eat a fat-free meal the night prior to having abdominal, gallbladder, liver, pancreas, or kidney sonograms.
- Premedications are seldom given unless the patient is extremely apprehensive or has nausea and vomiting.
- Conductive gel is applied to the skin surface at the site to be examined. The transducer is handheld and is moved smoothly back and forth across the oiled or gel-skin surface.
- The patient's position may vary from supine to oblique, prone, semirecumbent, and erect.
- The average time for an ultrasound procedure is 30 minutes.
- The patient should not smoke or chew gum prior to the examination to prevent swallowing air.

Brain

- Remove jewelry and hairpins from neck and head.

Breast

- Handheld, real-time contact scanning over the palpable mass is the most widely used method for breast imaging.

- The automated system using full-breast water immersion and a reproducible, systematic survey is less widely used because of its higher cost, space requirements, and lack of real-time capability.
- No lotion or powder should be applied under the arm or on the breasts the day of the test.

Doppler

- The blood pressure will be taken at certain limb sites.

Eye and Eye Orbit

- Anesthetize the eye and eye area.
- With the contact method, the probe touches the corneal surface.

Heart and Liver

- Ask the patient to breathe slowly and to hold breath after deep inspiration.

Gynecologic

- A transvaginal exam may be required. A slender probe is covered with a protective sleeve, and gel is placed on the sleeve. The patient is asked to place the probe in the vagina.

Obstetrics (First Trimester), Pelvic and Renal

- The patient should drink 24 ounces of water 1 hour prior to the examination, or three to four 8-ounce glasses of clear liquid 90 minutes prior to the test. The patient should not void until the test is completed. Second- and third-trimester patients need not drink a large amount of water *unless* bleeding has occurred, in which case the above procedure is followed.

Prostate

- Administer an enema 1 hour prior to the test.
- The patient should drink two 8-ounce glasses of clear fluid 1 hour prior to the test.
- The patient should *not* void 1 hour prior to the test.
- The patient lies on his left side.
- Rectal examination is usually performed before the transducer is inserted into the rectum. Lubricate the rectal probe and insert it into the rectum. The test takes approximately 1/2 hour.

Scrotum

- The penis is strapped back to the abdominal area or covered with a towel.
- Gel is applied and the transducer is passed over the scrotum.

Factors Affecting Diagnostic Results

- Residual barium sulfate in the GI tract from previous x-ray studies will interfere with ultrasound results. Ultrasonography should be performed before barium studies.
- Air and gas (bowel) will not transmit the ultrasound beam.
- Excess fecal material in the colon and rectum (prostate).

Uric Acid (Serum)

Reference Values

Values may differ among laboratories.

Adult: *Male*: 3.5–8.0 mg/dL. *Female*: 2.8–6.8 mg/dL (normal range may differ slightly among laboratories). *Panic Values*: Greater than 12 mg/dL.

Child: 2.5–5.5 mg/dL.

Older Adult: 3.5–8.5 mg/dL.

Description

Uric acid is a by-product of purine metabolism. Elevated urine and serum uric acid levels (hyperuricemia) depend on renal function, purine metabolism rate, and dietary intake of purine foods. Excess quantities of uric acid are excreted in the urine. Uric acid can crystallize in the urinary tract in acidic urine; therefore, effective renal function and alkaline urine are necessary with hyperuricemia. The most common problem associated with hyperuricemia is gout. Uric acid levels frequently change from day to day; thus several uric acid levels may be repeated over several days or weeks.

Patients with elevated serum uric acid should avoid foods high in purine.

Purpose

- To monitor serum acid during treatment for gout.
- To aid in the diagnosis of health problems (e.g., gout, alcoholism, leukemias, renal failure, Wilson disease).

Uric Acid (Urine—24 Hour)

Reference Values

Adult: 250–500 mg/24 h (low-purine diet), 250–750 mg/24 h (normal diet).

Child: Similar to adult.

See Uric Acid (serum) for Description and Purpose.

Urinalysis (Routine)

Reference Values

Adult	
Color	Light straw to dark amber
Appearance	Clear
Odor	Aromatic
pH	4.5–8.0; average is 6
Specific gravity (SG)	1.005–1.030 (1.015–1.024, normal fluid intake)
Protein	(2–8 mg/dL negative reagent strip test)
Glucose	Negative
Ketones	Negative
Blood	Negative
Microscopic examination	
RBC	1–2 per low-power field
WBC	3–4
Casts	Occasional hyaline

	Newborn	Child
Color		Light straw to dark yellow
Appearance	Clear	Clear
Odor		Aromatic
pH	5–7	4.5–8
Specific gravity (SG)	1.001–1.020	1.005–1.030
Protein		
Glucose		Negative
Ketones		Negative
Blood		Negative
Microscopic examination		
RBC		Rare
WBC		0–4
Casts		Rare

Description

Urinalysis is a physical, chemical, and microscopic analysis of the urine. Multiple-reagent strips are used for quick chemical screening.

Many routine urinalyses are done in the healthcare provider's office as well as in the hospital or in a private laboratory. The color, appearance, and odor of the urine are examined, and the pH, protein, glucose ketones, and bilirubin are tested with the reagent strips. Specific gravity is measured with a urinometer, and a microscopic examination of the urinary sediment is performed to detect red and white blood cells, casts, crystals, and bacteria.

Purpose

- To aid the diagnosis of a renal disorder.
- To detect metabolic disease not related to the kidneys.
- To detect glycosuria.
- To detect normal versus abnormal urine components.

Urobilinogen (Urine)

Reference Values

Adult: *Random:* Negative or less than 1.0 Ehrlich units. *2-Hour Specimen:* 0.3–1.0 Ehrlich units. *24-Hour Specimen:* 0.5–4.0 mg/24 h, 0.5–4.0 Ehrlich unit/24 h, 0.09–4.23 $\mu\text{mol}/24\text{ h}$ (SI units).

Child: Similar to adult.

Normal Findings

Normal lung tissue with normal gas distribution in both lungs.

Description

Bile, which is formed mostly from conjugated bilirubin, reaches the duodenum, where the intestinal bacteria change the bilirubin to urobilinogen. Most of the urobilinogen is lost in the feces. A large amount goes back to the liver through the bloodstream, where it is reprocessed to bile, and approximately 1% is excreted by the kidneys in the urine.

In early hepatitis, mild liver cell damage, or mild toxic injury, the urine urobilinogen level will increase despite an unchanged serum bilirubin level. The urobilinogen level will frequently decrease with severe liver damage, because less bile will be produced. The urobilinogen test might be performed with the urinalysis.

Purpose

- To aid in determining liver damage, hemolytic disease, and severe infections.

Ventilation (V/Q) Scan, Pulmonary Ventilation Scan

Normal Findings

Normal lung tissue with normal gas distribution in both lungs.

Description

The ventilation scan is a nuclear scan of the lungs. The patient inhales a mixture of air, oxygen, and radioactive gas (xenon [^{127}Xe or ^{133}Xe] or krypton 81 [^{81}Kr]). A single-breath scan is taken first. Then three phases of scanning follow: (1) the wash-in (single inspiration) phase, which is the buildup of gas distribution in the lungs; (2) the equilibrium phase, in which radioactive gas reaches a steady state; and (3) the washout phase, in which room air is breathed to remove radioactive gas from the lungs.

The pulmonary perfusion scan indirectly evaluates problems related to blood flow to the lungs (e.g., pulmonary embolism). The radioactive substance used is technetium, and images are taken by a gamma camera. A ventilation scan can reveal decreased ventilation (uptake of radioactive gas) caused by chronic obstructive lung disease, atelectasis, and pneumonia, although the pulmonary perfusion scan is normal. However, pulmonary embolus can cause an abnormal perfusion scan and a normal ventilation scan.

Purpose

- To differentiate between a ventilatory problem and vascular abnormalities in the lung.
- To evaluate low blood oxygen saturation.
- To evaluate and stage persons with COPD, lung cancer, and bronchial obstruction.

Procedure

- Food and fluids are not restricted.
- Remove all metal objects (jewelry) from around the neck and chest.
- The patient inhales the radioactive gas. The patient will be asked to take a deep breath and to hold it for a short time (single breath) while the scanner takes an image of the lung. Other images will be recorded during three phases of the test: wash-in, equilibrium, and washout and lung perfusion. The patient should breathe normally during all phases except the initial breathhold phase.

Nursing Implications with Rationale Ventilation Scan

- Assess respiratory status. Note and report changes in rate and difficulty in breathing. Check breath sounds.
- Assess communications for verbal and nonverbal expressions of anxiety and fear about tests and/or potential or actual problems.
- Report if the patient is having chest pain, especially if pulmonary embolism is suspected.
- Be supportive of the patient and family members prior to the test. Answer questions, or refer the questions to appropriate healthcare professionals.

Patient Teaching

- Explain the procedure to the patient (*see Procedure*). Tell the patient that the amount of radioactive gas is minimal.
- Instruct the patient to remove all jewelry from the chest and neck area.

Factors Affecting Diagnostic Results

- Metal objects could cause inaccurate recorded images.

White Blood Cell (WBC) Total (Blood)

Leukocytes

Reference Values

Adult: *Total WBC Count*: 4500–10,000 μL (mm^3).

Child: *Newborn*: 9000–30,000 μL ; *2 Years*: 6000–17,000 μL ;
10 Years: 4500–13,500 μL .

Description

(*See White Blood Cell Differential [Blood].*)

White blood cells (WBCs), or leukocytes, are divided into two groups: the polymorphonuclear leukocytes (neutrophils, eosinophils, and basophils) and the mononuclear leukocytes (monocytes and lymphocytes). Leukocytes are a part of the body's defense system; they respond immediately to foreign invaders by going to the site of involvement. An increase in WBCs is called *leukocytosis*, and a decrease in WBCs is called *leukopenia*.

Purpose

- To determine the presence of an infection.
- To check WBC values for diagnosing other health problems.

Factors Affecting Laboratory Results

- Drugs that can increase and decrease the WBC count.
- The time the blood sample was taken. The WBC count is lower in the morning than in the afternoon.
- The age of the individual. Children can have a high WBC count, especially during the first 5 years of life.

White Blood Cell Differential (Blood)

Reference Values

WBC Type	Differential WBC Values	
	Adult	
	%	μL (mm^3)
Neutrophils (total)	50–70	2500–7000
Segments	50–65	2500–6500
Bands	0–5	0–500
Eosinophils	1–3	100–300
Basophils	0.4–1.0	40–100
Monocytes	4–6	200–600
Lymphocytes	25–35	1700–3500

WBC Type	Differential WBC Values	
	Child	
	Same as Adult Except	
Neutrophils (total)	<i>Newborn</i> : 61%; <i>1-year-old</i> : 32%	
Segments	<i>1–12 years</i> : 4–9%	
Bands	<i>Newborn</i> : 34%; <i>1 year</i> : 60%	
Eosinophils	<i>6 years</i> : 42%; <i>12 years</i> : 38%	
Basophils		
Monocytes		
Lymphocytes		

Description

The differential white blood cell (WBC) count, part of the complete blood count (CBC), is composed of five types of WBCs (leukocytes): neutrophils, eosinophils, basophils, monocytes, and lymphocytes. The differential WBC count is expressed as cubic millimeters (mm^3 , μL) and percentage of the total number of WBCs. Neutrophils and lymphocytes make up 80–90% of the total WBCs. The differential WBC count provides more specific information related to infections and the disease process.

Neutrophils: Neutrophils are the most numerous circulating WBCs, and they respond more rapidly to the inflammatory and tissue injury sites than other types of WBCs. During an *acute* infection, the neutrophils are the body's first line of defense. The segments are mature neutrophils, and the bands are immature ones that multiply quickly during an acute infection.

Eosinophils: Eosinophils increase during allergic and parasitic conditions. With an increase in steroids, either produced by the adrenal glands during stress or administered orally or by injection, eosinophils decrease in number.

Basophils: Basophils increase during the healing process. With an increase in steroids, the basophil count will decrease.

Monocytes: Monocytes are the second line of defense against bacterial infections and foreign substances. They are

stronger than neutrophils and can ingest larger particles of debris. Monocytes respond late during the acute phase of the infection and inflammatory process, and they continue to function during the chronic phase of phagocytes.

Lymphocytes: Increased lymphocytes (lymphocytosis) occur in chronic and viral infections. Severe lymphocytosis is commonly caused by chronic lymphocytic leukemia. Lymphocytes play a major role in the immune response system as B lymphocytes and T lymphocytes. Like eosinophils, lymphocytes decrease in number during excess adrenocortical hormone secretion or steroid therapy.

Purpose

- To differentiate between various types of WBCs for diagnosing health problems (see Description).

Factors Affecting Laboratory Results

- Steroids could decrease eosinophil and lymphocyte values.
- Certain drugs can increase or decrease blood values.

X-Ray (Chest, Heart, Flat Plate of Abdomen, Kidney, Ureter, Bladder, and Skull)

Normal Findings

Chest: Normal bony structure and normal lung tissue.

Heart (Cardiac): Normal size and shape of the heart and vessels.

Flat Plate of Abdomen: Normal abdominal structures.

Kidney, Ureter, Bladder (KUB): Normal kidney size and structure.

Skeletal: Normal bone structures.

Skull: Normal structure.

Description

There are four densities in the human body—air, water, fat, and bone—that will absorb varying degrees of radiation. Air has less density, causing dark images on the film, and bone has high density, causing light images. Bone contains a large amount of calcium and will absorb more radiation, thus allowing less radiation to strike the x-ray film; thus a white structure is produced.

The chest x-ray is one of the diagnostic tests most often ordered by the healthcare provider. A skull x-ray is usually ordered following head trauma. Requests for cardiac, flat plate of abdomen, and kidney-ureter-bladder (KUB) x-rays have increased in the past two decades. X-ray studies are requested primarily for screening purposes and then are followed by other extensive diagnostic tests.

Purpose

- To identify bone structure and tissue in the body.
- To detect abnormal size, structure, and shape of bone and body tissues.

Nursing Implications with Rationale X-Ray

- Describe the x-ray procedure to the patient.

Patient Teaching

- Inform the patient that the x-ray test usually takes 10–15 minutes.
- Inform the patient that several x-rays may be taken, one or two chest films, or five skull films. The patient may be asked to remain in the waiting room for 10–15 minutes after x-rays are taken to be sure the films are readable.
- Encourage the patient to ask questions or to express her concerns to the nurse, physician, and the technician. Also, if the patient does not understand the directions, she should ask to have them repeated.
- Ask the female patient if she is pregnant or if pregnancy is suspected. X-rays should be avoided during the first trimester of pregnancy. If x-ray of the chest is necessary, the female patient should wear a lead apron covering the abdomen and pelvic areas. Some dentists have women of childbearing age (12–48 years old) wear lead aprons.
- Explain to the patient that the x-ray equipment and film today are of good quality and decrease the exposure to radiation.

Procedure

Chest

- Food and fluids are not restricted.
- PA chest film is usually ordered with the patient standing. An anteroposterior (AP) chest film may be ordered when PA film cannot be obtained. With an AP chest film, the patient is sitting or lying down. A lateral chest film may also be ordered.
- Clothing and jewelry should be removed from the neck to the waist, and a paper or cloth gown should be worn.
- The patient should take a deep breath and hold it as the x-ray is taken.

Heart

- Food and fluids are not restricted.
- Posteroanterior (PA) and left-lateral chest films are usually indicated for evaluating the size and shape of the heart. The left anterior oblique (LAO) 60-degree rotation with the PA position may be ordered for cardiac evaluation.
- Clothing and jewelry should be removed from the neck to the waist, and a paper or cloth gown should be worn.
- Patient instructions will include body position (usually standing) and when to take a deep breath and hold it.

Abdomen and KUB

- Food and fluids are usually not restricted.
- X-rays should be taken before an intravenous pyelogram or gastrointestinal studies.
- Clothes are removed, and a paper or cloth gown is worn.
- The patient lies in the supine position with his or her arms away from the body on a tilted x-ray table.
- The testes should be shielded as an added precaution.

Skull

- Food and fluids are not restricted.
- The patient should remove hairpins, glasses, and dentures before the x-ray tests.
- The patient will be asked to assume various positions so that different areas of the skull can be x-rayed. X-rays may include the facial bones and sinuses.

Skeletal

- The patient should be NPO if a fracture is suspected.
- Immobilize suspected fracture site.

Factors Affecting Diagnostic Results

- Radiopaque materials for IVP and GI studies administered within 3 days of routine x-rays (i.e., chest, flat plate of abdomen, and KUB) could distort the pictures.
- Incorrect positioning of the patient could produce distorted pictures.
- Obesity and ascites could affect the clarity of the x-ray film.

This page intentionally left blank

Glossary

ABC The essential functions of airway, breathing, and circulation.

ABCD An enhancement of the **ABC** mnemonic, with the **D** representing one of four indicators depending on agency use: defibrillation, deficiency, deadly bleeding, or disability.

Abortion Loss of pregnancy before the fetus is viable outside the uterus. Also called *miscarriage*.

Absence seizures Also called petit mal seizures, absence seizures involve both hemispheres of the brain as well as deeper structures such as thalamus, basal ganglia, and upper brainstem. They are considered a type of generalized seizure.

Absorption The process of moving nutrients and fluid from the external environment of the gastrointestinal tract to the internal environment. May also refer to the intake of any specific nutrient.

Abstinence Voluntarily going without alcohol, drugs, or other pleasurable substances or activities.

Abuse of power An attempt by an individual to use his or her position or authority in a manner that shames, controls, demeans, humiliates, or denigrates another individual to gain emotional, psychological, or physical advantage over that individual.

Accelerations A transient increase in the fetal heart rate normally caused by fetal movement.

Accommodation 1. The ability of the eye to adjust to variations in distance. 2. The process of a change whereby cognitive processes mature sufficiently to allow an individual to solve problems that were unsolvable before.

Accountability The ability and willingness of an individual to assume responsibility for his or her actions and to accept the consequences of his or her behavior.

Accreditation A peer review process that evaluates and certifies the quality of an organization.

Acculturation The process of adapting to the majority culture and accepting it as one's own.

Acid indigestion A condition in which an individual can taste the stomach acid when it flows back into the esophagus.

Acidosis The condition that results when hydrogen ion concentration increases above normal, causing the pH to drop below 7.35.

Acids Substances that release hydrogen ions in solution.

Acquaintance phase The first few days after a child's birth, when the new mother applies herself to the task of getting to know her baby.

Acquaintance rape A broad term used to describe a rape committed by an acquaintance or other familiar individual.

Acquired immunity Immunity developed after exposure to a pathogen.

Acquired immunodeficiency syndrome (AIDS) An immune system deficit induced by infection with the human immunodeficiency virus (HIV). AIDS is characterized by opportunistic infections.

Acrocyanosis A bluish discoloration of the hands and feet.

Acromegaly Excessive growth of bone from growth hormone hypersecretion.

Actinic keratosis An epidermal skin lesion directly related to chronic sun exposure and photodamage. Also called *senile keratosis* or *solar keratosis*.

Action potential The electrical activity produced by movement of ions across cell membranes that stimulates muscle contraction.

Active acquired immunity Antibodies formed in response to an illness or an immunization while a woman is pregnant.

Active euthanasia Actions to bring about a patient's death directly, with or without patient consent.

Active immunity Production of antibodies or development of immune lymphocytes against specific antigens.

Active listening Fully concentrating on both the content and emotion of a person's message, rather than just passively hearing the words a person says.

Active transport A method that requires additional energy (in the form of adenosine triphosphate) to move substances against the concentration gradient (from low concentration to high concentration).

Activities of daily living (ADLs) Activities used routinely in daily life, such as grooming, eating, bathing, and dressing.

Activity-exercise pattern An individual's routine of exercise, activity, leisure, and recreation, including activities of daily living that require energy expenditure.

Activity tolerance The type and amount of exercise or daily living activities that an individual is able to perform without experiencing adverse effects.

Actual loss A change in or unavailability of something or someone of value that can be recognized by others.

Acute coronary syndrome (ACS) Any condition that develops due to sudden, reduced blood flow to the heart.

Acute fatigue A sudden onset of physical and mental exhaustion or weariness, particularly after a period of mental or physical stress.

Acute illness An alteration in health or functioning characterized by severe symptoms of relatively short duration.

Acute infection An infection that appears suddenly and lasts for a short time.

Acute kidney injury (AKI) Proposed as a more accurate term for *acute renal failure*, AKI is defined as a sudden decline in kidney function that causes disturbances in fluid, electrolyte, and acid-base balances.

Acute lymphocytic leukemia (ALL) The most common type of leukemia in children and adolescents, marked by the proliferation of malignant cells that resemble immature lymphocytes.

Acute myeloid leukemia (AML) A disorder characterized by uncontrolled proliferation of myeloblasts and hyperplasia of the bone marrow and spleen.

Acute myocardial infarction (AMI) A life-threatening condition that occurs when blood flow to a portion of the cardiac muscle is blocked. If circulation to the affected myocardium is not promptly restored, loss of functional myocardium affects the heart's ability to maintain an effective cardiac output, ultimately leading to cardiogenic shock and death.

Acute pain Temporary, localized, and sudden pain that lasts for less than 6 months and has an identifiable cause, such as trauma, surgery, or inflammation.

Acute pancreatitis An inflammatory disorder that involves self-destruction of the pancreas by its own enzymes through autodigestion.

Acute postinfectious glomerulonephritis (APIGN) Inflammation of the glomerular capillary membrane that is most often seen in children as a response to a group A beta-hemolytic streptococcal infection of the skin or pharynx or as a result of infection by *Staphylococcus*, *Pneumococcus*, or Coxsackie virus.

G-2 Glossary

Acute renal failure (ARF) A rapid decline in renal function with azotemia, fluid, and electrolyte imbalances. ARF may be reversed with prompt intervention.

Acute respiratory distress syndrome (ARDS) A disorder with rapid onset characterized by noncardiac pulmonary edema and progressive refractory hypoxemia. ARDS is a life-threatening emergency.

Acute retroviral syndrome (ARS) Primary human immunodeficiency virus infection.

Acute stress disorder A condition that may occur following an individual experiencing, learning of, or witnessing an extremely stressful event that involves the threat of death, actual or threatened serious injury, or actual or threatened physical or sexual violation.

Acute tubular necrosis (ATN) The destruction of tubular epithelial cells, which causes an abrupt and progressive decline of renal function.

Adaptation 1. The ability to handle the demands made by the environment. Also called *coping behavior*. 2. The return to normal functioning, even when homeostasis cannot be regained.

Adaptation phase The phase during a crisis in which the individual meets the challenges presented and uses his or her resources to successfully resolve the crisis.

Adaptive behavior Everyday skills, including conceptual skills, social skills, and practical skills.

Adaptive functioning The ability of an individual to meet the standards expected for his or her cultural group.

Adaptive mechanisms Methods the ego uses to fulfill the needs of the id in a socially acceptable manner. Also called *defense mechanisms*.

Addiction A psychologic or physical need for a substance (such as alcohol) or process (such as gambling) to the extent that the individual will risk negative consequences in an attempt to meet the need.

Addictive behaviors Compulsive, problematic patterns of action resulting in psychologic and/or physiologic dependence.

Addison disease A disorder that results from adrenal insufficiency, particularly a cortisol deficiency.

Adherence Commitment or attachment to a regimen. Also called *compliance*.

Adhesions Fibrous bands of scar tissue.

Adjustment disorder with depressed mood A maladaptive reaction to an identifiable psychosocial stressor or stressors that occurs within 3 months after the onset of the stressor and has persisted for no longer than 6 months. Also called *adjustment disorder* or *situational depression*.

Adjustment phase Initial phase experienced in response to crisis, characterized by disorganization and unsuccessful attempts to meet the crisis.

Adjustment reaction to depressed mood See Postpartum blues.

Administrative laws Responsibilities that may be interpreted and enforced by an agency that has been delegated the power of oversight by the governing legislation.

Adolescent family A family in which one or more parents are adolescents.

Advance healthcare directives Legal documents that allow an individual to plan for healthcare and/or financial affairs in the event of incapacity. Also called *advance directives* or *healthcare advance directives*.

Advocacy Protecting an individual by expressing and defending the individual's cause on his or her behalf.

Advocate An individual who expresses and defends the cause of another.

Aerobic exercise An activity during which the amount of oxygen taken into the body is greater than that used to perform the activity.

Aesthetic knowing The subjective elements and personal style a nurse uses when delivering care, including empathy, holistic thinking, compassion, and sensitivity.

Afebrile Without fever.

Affect The immediate and observable emotional expression of mood, which people communicate verbally and nonverbally; the outward manifestation of what the individual is feeling.

Affective commitment An attachment to a profession that includes identification with and involvement in the profession.

Affective domain The learning domain encompassing an individual's emotional response to tasks, including feelings, emotions, interests, attitudes, and appreciation. Also called the *feeling domain*.

Afterload The force that ventricles must overcome to eject their blood volume.

Afterpains Cramplike pains caused by intermittent contractions of the uterus that occur after childbirth.

Age-related macular degeneration (AMD) A gradual degeneration in the macular area of the retina that is the leading cause of blindness in people over age 65.

Ageism A deep and profound prejudice in American society against older adults.

Aggravated assault An unlawful attack by one individual on another for the purpose of inflicting severe or aggravated bodily injury. This type of assault usually is accompanied by the use of a weapon or by means likely to produce death or great bodily harm.

Aggression Any form of behavior directed toward the goal of harming or injuring another living being.

Aggressive behavior Behavior directed toward getting what one wants without considering the feelings of others.

Aggressive communicators Individuals who tend to focus on their own needs and become impatient when these needs are not met.

Agnosia The inability to recognize one or more objects that previously were familiar.

Agoraphobia A condition that is characterized by anxiety associated with two or more of the following situations: being in enclosed spaces, being in open spaces, using public transportation, being in a crowd or standing in a line of people, or being alone outside the home environment.

Agraphia The inability to write properly.

AIDS dementia complex The most common cause of mental status changes for patients with HIV infection. This dementia results from a direct effect of the virus on the brain and affects cognitive, motor, and behavioral functioning. Fluctuating memory loss, confusion, difficulty concentrating, lethargy, and diminished motor speed are typical manifestations.

Air trapping Decreased airflow with exhalation caused by edema of the air passages.

Airborne precautions Used for patients who are known to have or suspected of having serious illnesses transmitted by airborne droplet nuclei smaller than 5 microns, such as tuberculosis.

Airway clearance techniques Nonpharmacologic strategies for clearing the airway. Examples include coughing, huffing, and **chest physical therapy**.

Airway remodeling Structural changes of the airway caused by a disease, such as asthma, resulting in progressive or permanent loss of lung function.

Airway resistance The effort or force needed to move oxygen through the trachea to the lungs.

Akathisia Restlessness.

Alcohol dependence A primary, chronic disease characterized by use or abuse of alcohol; genetic, psychosocial, and environmental factors influence its development and manifestations. Also called *alcoholism*.

Alcohol poisoning A toxic condition that results from excessive consumption of large amounts of alcohol in a very short period of time.

Alcohol withdrawal delirium A medical emergency usually occurring 3–5 days following alcohol withdrawal and lasting 2–3 days. Characterized by paranoia, disorientation, delusions, visual hallucinations,

elevated vital signs, vomiting, diarrhea, and diaphoresis. Also known as *delirium tremens* (DTs).

Alcohol withdrawal syndrome Condition that typically begins about 6–8 hours after an individual with alcoholism takes his or her last drink. Early symptoms include irritability, anxiety, insomnia, tremors, sweating, and a mild tachycardia.

Alcoholic cirrhosis A progressive, irreversible liver disorder resulting from excessive consumption of alcohol. Also called *Laënnec cirrhosis*.

Alcoholism A primary, chronic disease characterized by use or abuse of alcohol; genetic, psychosocial, and environmental factors influence its development and manifestations. Also called *alcohol dependence*.

Alkalosis The condition that results when hydrogen ion concentration falls below normal and the pH level rises above 7.45.

Allen test A measurement of radial or ulnar artery patency; either the radial or ulnar artery is digitally compressed by the examiner after blood has been forced out of the hand by clenching it into a fist.

Allergen An environmental or exogenous antigen that provokes a hypersensitivity response.

Allergic contact dermatitis A cell-mediated or delayed hypersensitivity to a wide variety of allergens.

Allergy A hypersensitivity response to environmental or exogenous antigens.

Allogeneic blood transfusion A transfusion using blood that has been donated by the community.

Allogeneic bone marrow transplant A transplant using bone marrow from a matched donor.

Allografts Grafts between members of the same species who have different genotypes and HLA antigens. Human skin that has been harvested from cadavers is usually used. Also called *homograft*.

Alloimmunization The reaction of the immune system to donated tissue.

Allostasis Necessary changes that must occur to achieve the characteristic stability of homeostasis.

Allostatic load The physical cost of adaptation to physiologic or psychosocial stressors.

Alogia Limited or impoverished speech.

Alopecia Hair loss.

Alternative therapies (also referred to as *alternative medicine*) A term used to describe use of these diverse therapies *instead of* conventional therapies, including acupuncture; cultural practices related to food preparation or practices at specific times of the day or during the week.

Altruism A concern for the welfare and well-being of others.

Alveoli Terminal structures of the respiratory system where gas exchange occurs.

Alzheimer disease (AD) The most common kind of dementia, Alzheimer disease involves progressive dementia, memory loss, and the inability to care for one's self.

Ambulation The ability to walk from place to place independently with or without an assistive device.

Amblyopia Lazy eye; one eye has reduced vision even with no identifiable cause, and the reduced vision is not correctable by corrective lenses.

Amenorrhea The absence of menstruation.

Amniocentesis A procedure used to obtain amniotic fluid for genetic testing to determine fetal abnormalities or fetal lung maturity in the third trimester of pregnancy.

Amnion A thin protective membrane that contains amniotic fluid.

Amniotic fluid The liquid surrounding the fetus in utero. It absorbs shocks, permits fetal movement, and prevents heat loss.

Amphetamine A powerful stimulant that, when used improperly or abused, poses a severe health risk due to its devastating physical and

neurologic consequences, including amphetamine-induced mental disorders.

Ampulla The outer third of the fallopian tube, where fertilization usually occurs.

Amyloid plaques Seen in Alzheimer disease and formed when groups of nerve cells degenerate and clump around the amyloid core in the spaces between the neurons in the brain. Amyloid plaques consist primarily of insoluble deposits of beta-amyloid, a protein fragment from a larger protein called amyloid precursor protein, mixed with other neurons and nonnerve cells.

Anaerobic exercise Activity in which the muscles cannot draw out enough oxygen from the bloodstream, and anaerobic pathways are used to provide additional energy for storing for a short time.

Anal stimulation The stimulation of the anus with the fingers, mouth, or sex toys for sexual pleasure.

Anaphylactic shock Shock resulting from a widespread hypersensitivity reaction. Also called *anaphylaxis*.

Anaphylaxis An acute systemic type I hypersensitivity (allergic) response that may result in shock and death. It occurs in highly sensitive persons following exposure to a specific antigen, usually through injection or ingestion.

Anaplasia The regression of a cell to an immature or undifferentiated cell type.

Anasarca Severe, generalized edema.

Andragogy The art and science of teaching adults.

Androgen A hormone that stimulates the development and maintenance of male sex characteristics.

Androgyny Flexibility in gender roles.

Anemia An abnormally low number of circulating red blood cells, low hemoglobin concentration, or both.

Anergic Unable to react to common antigens.

Anergy Fatigue and decreased energy associated with a depressive disorder. Also called *anergia*.

Anger A subjective sense of intense displeasure, irritation, or animosity.

Angina pectoris Chest pain resulting from reduced coronary blood flow caused by a temporary imbalance between myocardial blood supply and demand. Also called *angina*.

Angle-closure glaucoma A type of glaucoma that results from a narrowing of the anterior chamber angle due to corneal flattening or bulging of the iris into the anterior chamber. Also called *narrow-angle* or *closed-angle glaucoma*.

Anhedonia The inability to feel pleasure.

Animism Giving lifelike qualities to nonliving things.

Anion Ion that carries a negative charge.

Anomia Difficulty naming people and things.

Anorexia Loss of appetite.

Anorexia nervosa (AN) A potentially life-threatening disorder characterized by extreme perfectionism, weight fear, significant weight loss, body image disturbances, strenuous exercising, peculiar food-handling patterns, and reductions in heart rate, blood pressure, metabolic rate, and the production of estrogen or testosterone.

Anorgasmia Absence of orgasm.

Antagonism One of the six trait domains associated with personality disorders that is composed of manipulativeness, deceitfulness, callousness, hostility, grandiosity, and attention seeking.

Antepartum Time between conception and the onset of labor; usually used to describe the period during which a woman is pregnant.

Anthropometric measurements Measurements that can help identify individuals who are at risk for undernutrition or overnutrition. Specific measurements include height, length (in babies), weight, body mass index, waist-to-hip circumference, and skinfold thickness.

G-4 Glossary

Antibodies Proteins that work against antigens.

Antibody-mediated (humoral) immune response Activation of B cells to produce antibodies to respond to antigens such as bacteria, bacterial toxins, and free viruses.

Anticipatory grief Grief experienced in advance of a loss, such as the wife who grieves before her ailing husband dies.

Anticipatory guidance Information about developmental changes that can be expected in the future. Including the recognition of the potential for a crisis and assistance with identifying potential methods for averting the crisis.

Anticipatory learning Learning necessary to effectively reach a desired outcome or in anticipation of a need for information that has not yet occurred.

Anticipatory loss A loss that is experienced before the loss actually occurs. For example, the gradual decline and eventual death of a family member who has Alzheimer disease.

Anticipatory problem solving Initial information is presented to a learner, who is then asked a question or presented with a situation related to the information. The learner applies the new information to the situation and decides what to do.

Antigen Foreign substance that triggers the immune response.

Antigen-antibody complex The complex formed by the binding of an antibody to an antigen.

Antigenic drift Describes small changes that occur continuously as a virus makes copies of itself.

Antigenic shift When two different strains of a virus infect the same cell and exchange genetic material to create a new subtype of the virus.

Antiretroviral therapies Pharmacologic therapies that stop or suppress the activity of a retrovirus, preventing further weakening of the immune system and thereby minimizing opportunistic infections.

Antiseptics Agents that inhibit the growth of some microorganisms.

Antisocial personality disorder (ASPD) One of several types of personality disorders defined by the DSM-5, it is characterized by a pattern of disregard for and violation of the rights of others.

Anuria The failure of the kidneys to produce urine, resulting in a total lack of urination or output of less than 100 mL/day in an adult.

Anxiety A stress response characterized by feelings of apprehension, dread, mental uneasiness, and a sense of helplessness in response to an actual or perceived threat to the well-being of oneself or others.

Anxious distress A combination of symptoms often associated with anxiety, including restlessness, impaired concentration due to worry, fear of something awful happening, and fear of losing control. Anxious distress often manifests in patients with depression and bipolar disorders and is associated with an increased risk for suicide.

Aortic stenosis Narrowing of the aortic valve that obstructs blood flow to systemic circulation.

Apathy A lack of interest or enthusiasm.

Apgar score A physical assessment of a newborn at 1 minute and 5 minutes after birth on a scale from 1 to 10 that includes heart rate, respiratory effort, muscle tone, reflex irritability, and skin color.

Aphakia Absence of the lens of the eye (e.g., after surgical removal of a cataract).

Aphasia Defective or absent language function.

Apical-radial pulse A comparison of the apical and radial pulses, which are normally identical. A pulse deficit can indicate certain cardiovascular disorders.

Aplastic anemia A disorder that results when the bone marrow fails to produce all three types of blood cells.

Apnea Absence of breathing.

Apnea of prematurity Absence of breathing for 20 seconds or longer, or for less than 20 seconds when associated with cyanosis, pallor, and

bradycardia. A common problem in a preterm infant of less than 36 weeks' gestation, usually presenting between day 2 and day 7 of life.

Appendectomy Surgical removal of the appendix.

Appendicitis Inflammation of the vermiform appendix.

Appendicular skeleton Pectoral girdles, upper limbs, pelvic girdle, and lower limbs.

Approach-coping The use of confrontation to change the stressor by taking direct action.

Approximated Term describing successful closure of a wound with little or no tissue loss.

Apraxia The inability to perform purposeful movements and use objects correctly.

Areflexia The loss of reflex function.

Areola Pigmented ring surrounding the nipple of the breast.

Arousal In the brain, arousal, or alertness, is regulated by the **reticular activation system**.

Arrhythmogenic tissue Tissue that affects the generation and conduction of electrical impulses in the heart.

Arrogance Excessive pride and a feeling of superiority.

Arrhythmogenic right ventricular dysplasia (ARVD) A condition that results when the body progressively replaces the muscle of the right ventricle with fatty and fibrous tissue.

Arterial blood gas (ABG) A laboratory test used to evaluate oxygen and carbon dioxide exchange and the acid-base balance within the blood.

Arterial blood pressure A measure of the pressure exerted by the blood as it flows through the arteries.

Arteriosclerosis An arterial disorder characterized by thickening, loss of elasticity, and calcification of arterial walls.

Arteriovenous (AV) fistula An artificial connection between a vein and an artery created for long-term vascular access.

Arthrodesis A procedure that permanently fuses two or more bones together at a joint using pins, plates, screws, and rods. Also called *joint fusion*.

Arthroplasty Total joint replacement.

Arthroscopy A surgical procedure in which a thin, lighted tube with a camera in one end is inserted into a joint in order to allow a surgeon to visualize joint structure more easily.

Artificial disc surgery Surgery to replace a herniated disc with an artificial disc in order to maintain flexibility of the spinal joint.

Artificial rupture of membranes A process of rupturing of the membranes by the certified nurse-midwife or physician using an instrument called an amniohook. Completed if spontaneous rupture of membranes does not occur.

ASA Physical Classification Scale A physical risk classification category that determines the type and dosage of sedation a patient can receive.

Ascites Excess fluid in the peritoneal cavity.

Asepsis The absence of disease-causing organisms.

Assault The action of creating an apprehension of offensive, insulting, or physically injurious touching.

Assertive behavior Behavior that consists of expressing one's wishes and opinions, or taking care of oneself, but not at the expense of others.

Assertive communicators Individuals who tend to declare and affirm their opinions. In doing this, however, they respect the rights of others to communicate in the same fashion.

Assertive community treatment (ACT) A therapeutic regimen for individuals with moderate to severe mental illness that provides patients with individually tailored services within their communities.

Assessment The systematic and continuous collection of data about a patient for the purpose of determining the patient's current and ongoing

health status, predicting the patient's health risks, and identifying appropriate health-promoting activities.

Assignment The transfer of responsibility to accomplish a task, without the transfer of authority.

Assimilation 1. The process of adapting to and integrating characteristics of the dominant culture as one's own. 2. The process by which humans encounter and react to new situations by using the mechanisms they already possess.

Assisted suicide Self-administration of a lethal dose of medication provided by a physician or healthcare provider in order to intentionally end a patient's life with the goal of relieving pain and suffering.

Associative play A stage of play in which children play together or share tasks during play.

Astereognosis The inability to identify objects by touch.

Asthma A chronic inflammatory disease of the lungs characterized by recurrent episodes of wheezing, breathlessness, chest tightness, and coughing.

Asynclitism A condition that occurs when the sagittal suture is directed toward either the symphysis pubis or the sacral promontory and is felt to be misaligned.

Asystole Cardiac standstill.

Ataxia Lack of muscle coordination.

Atelectasis Collapse of lung tissue following obstruction of the bronchus or bronchioles.

Atherectomy A procedure to remove plaque from a lesion, specifically an **atheroma**.

Atheroma Complex lesion consisting of lipids, fibrous tissue, collagen, calcium, cellular debris, and capillaries. The formation of atheromas is the final stage of **atherosclerosis**.

Atherosclerosis A form of arteriosclerosis in which deposits of fat and fibrin obstruct and harden the arteries.

Atrial gallop (S₄) A heart sound produced by atrial contraction and ejection of blood into the ventricle during late diastole. Also called the *fourth heart sound*.

Atrial kick An extra bolus of blood delivered to the ventricles before they contract.

Atrial natriuretic factor (ANF) A peptide hormone released from cells in the atrium of the heart in response to excess blood volume and stretching of the atrial walls.

Atrial septal defect (ASD) An opening in the atrial septum that permits left-to-right shunting of blood.

Atrioventricular (AV) canal defect A combination of defects in the atrial and ventricular septa and portions of tricuspid and mitral valves. A complete AV canal defect allows blood to travel freely among all four chambers of the heart. Also called *endocardial cushion defect*.

Atrophy The wasting away or decrease in size of an organ, muscle, or tissue.

Attention deficit disorder (ADD) A variation in central nervous system processing characterized by developmentally inappropriate behaviors involving inattention.

Attention-deficit/hyperactivity disorder (ADHD) A variation in central nervous system processing characterized by developmentally inappropriate behaviors involving inattention, hyperactivity, and impulsivity.

Attention impairment A condition marked by an inability to process information and respond to such information appropriately; a patient with attention impairment will have poor concentration and be easily distracted.

Attentive listening The process of listening actively, using all the senses. Also called *mindful listening*.

Attributes of safety The quality or properties of remaining safe.

Audiologist A healthcare professional specializing in identifying, diagnosing, treating, and monitoring disorders of the auditory and vestibular portions of the ear.

Audit An examination of records to verify accuracy and proper use.

Auditory Of or relating to hearing.

Aura An olfactory or visual sensory sensation that may provide an early warning sign of a seizure.

Auscultation Listening to the sounds produced within the body. Auscultation can be direct using the unaided ear or indirect using a stethoscope or other listening device.

Authority 1. The power to command other individuals and direct their activities. 2. The right to act or to accomplish the task.

Autism spectrum disorders (ASDs) A developmental disorder in which individuals have persistent deficits in social communication and social interaction, and restricted, repetitive patterns of behavior, interest, or activities.

Autoantibodies Antibodies that react to the individual's own tissues.

Autocratic (authoritarian) leader A leader who makes decisions for the group based on the belief that individuals are externally motivated and are incapable of independent decision making.

Autografting A procedure performed in the surgical suite in which part of a patient's healthy skin is removed and used to effect permanent skin coverage over a wound area.

Autoimmune disorder/disease Failure of immune system to recognize itself, resulting in normal host tissue being targeted by immune defenses.

Autologous blood transfusion A blood transfusion using a patient's own blood.

Autologous bone marrow transplant Bone marrow transplant using a patient's own bone marrow.

Automatism A repetitive reaction that occurs automatically, without conscious thought. Examples include lip smacking, eyelid fluttering, aimless walking, picking at clothing, and swallowing.

Autonomic dysreflexia An abrupt onset of excessively high blood pressure as the result of an overactive autonomic nervous system. An exaggerated sympathetic response that occurs in patients with spinal cord injuries at or above the T6 level. Also called *autonomic hyperreflexia*.

Autonomy 1. The state of being independent and self-directed without outside control. 2. The right to make one's own decisions.

Autosomal chromosomes Genetic material found in a cell nucleus that determines physical characteristics (excluding gender) of the individual.

Autosome A single chromosome from any one of the 22 pairs of chromosomes not involved in sex determination (X or Y); humans have 22 pairs of autosomes.

Avascular necrosis The death of bone tissue due to lack of blood supply. Also called *osteonecrosis*.

Avian influenza Also known as "bird flu," it is a form of influenza that commonly infects birds. This virus has not yet demonstrated the ability to spread among humans; however, concerns are that it will mutate to allow person-to-person spread. This viral strain has a mortality rate of greater than 50% in people who have been infected due to close association with infected birds.

Avoidance-coping The use of both behaviors and cognitive processes to avoid a stressor.

Avoidant personality disorder (APD) One of several types of personality disorders recognized by the DSM-5, APD is characterized by a pattern of social withdrawal along with a sense of inadequacy, fear, and hypersensitivity to potential rejection or shame.

Avolition The inability to persist in goal-directed activities.

Awareness The ability to perceive environmental stimuli and body reactions and to respond appropriately through thought and action.

Axial loading The application of vertical force to the spinal column.

Axial skeleton Ribs, sternum, vertebral column, and skull.

G-6 Glossary

Axon A nerve fiber.

Azotemia Increased levels of nitrogenous wastes in the blood.

B lymphocytes (B cells) Integral to specific immune response, they are activated and mature into either plasma cells, which secrete antibodies, or memory cells.

Babinski reflex The fanning and extension of the toes or flexion of the toes due to gentle stroking on the sole of the foot. Also called the *Babinski response*.

Bacilli Rod-shaped bacteria.

Background questions General questions asked of a patient that seek more information about a topic, such as diseases and medications.

Bacteremia The presence of bacteria in the blood.

Bacteria The most common category of infection-causing microorganisms.

Bactericidal agent Destroys bacteria.

Bacteriostatic agent Prevents the growth and reproduction of some bacteria.

Balanitis Inflammation of the glans.

Balloon tamponade The inflation of the balloon tip of a multiple-lumen nasogastric tube to control bleeding.

Barlow maneuver A procedure used to evaluate an infant for hip dislocation or instability in which the healthcare provider grasps and adducts the infant's thigh and then applies gentle downward pressure.

Barotrauma Lung injury caused by alveolar overdistention. Also called *volutrauma*.

Barrel chest An increase in the anteroposterior chest diameter resulting from air trapping and hyperinflation.

Basal cell carcinoma An epithelial tumor believed to originate either from the basal layer of the epidermis or from cells in the surrounding dermal structures. Also called *basal cell cancer*.

Basal metabolic rate (BMR) The amount of energy expended by the body at rest.

Base excess (BE) A calculated value also known as *buffer base capacity*. The BE measures substances that can accept or combine with hydrogen ions. It reflects the degree of acid-base imbalance by indicating the status of the body's total buffering capacity.

Baseline fetal heart rate The average fetal heart rate (FHR) rounded to increments of 5 bpm observed during a 10-minute period of monitoring. This excludes periodic or episodic changes, periods of marked variability, and segments of the baseline that differ by more than 25 bpm.

Baseline fetal heart rate variability Fluctuation in the FHR baseline of 2 cycles per minute or greater, with irregular amplitude and inconstant frequency.

Bases Substances that accept hydrogen ions in solution. Also called *alkalis*.

Basic needs The physical needs of an individual, such as eating, sleeping, resting, self-care, and physical stability.

Battery The willful touching of another individual, an individual's clothes, or even something the individual is carrying that is unwanted, embarrassing, or unwarranted.

Behavioral therapy A form of therapy in which patients learn techniques to modify or change maladaptive behaviors.

Behaviorist theory A theory that suggests that learning takes place when an individual's reaction to a stimulus is either positively or negatively reinforced.

Belief An interpretation or conclusion that one accepts as true.

Belief system The way in which a culture explains the mysteries of the universe and life.

Belt restraint Restraint used to ensure the safety of patients who are transported by wheelchair or gurney, or to protect patients confined to a bed or a chair. Also called *safety strap body restraint*.

Benchmarking A method used to compare the performance of an individual or organization to industry standards.

Beneficence The act of doing good or beneficial actions.

Benign Referring to a growth or tumor that does not endanger life or health and tends to not recur after treatment.

Benign prostatic hyperplasia (BPH) Nonmalignant enlargement of the prostate gland commonly seen in the aging man.

Bereavement The subjective response experienced by the surviving loved ones after the death of an individual with whom they have shared a significant relationship.

Bias The favoring of a group or individual over another.

Bidirectional influence Influences exerted between an individual and his or her family that may negatively affect the emotional health of the individual, the family, or both.

Bilevel ventilator (BiPAP) Mechanical ventilation that provides inspiratory positive airway pressure as well as airway support during expiration.

Biliary colic A severe, steady pain in the epigastric region or right upper quadrant of the abdomen.

Binge drinking The consumption of five or more drinks containing alcohol in a single session.

Binge eating The ingestion of huge amounts of food (about 3,500 kcal) within a short time (about 1 hour).

Binge eating disorder (BED) An eating disorder characterized by recurring episodes of binge eating, a sense of lack of control, and negative feelings about oneself, but without intervening periods of behavior such as self-induced vomiting, purging by laxatives, fasting, or prolonged exercise.

Binuclear family A postdivorce family in which the biologic children are members of two nuclear households—that of the father and that of the mother—and the children alternate between the two homes.

Bioethics The application of ethics to issues of human life or health (e.g., to decisions about abortion or euthanasia).

Bioethical dilemmas Ethical dilemmas of human life or health that arise in the care of patients and families; they often emerge from a combination of causative factors.

Biologic rhythm A cyclical event or function that consists of repeated occurrences and repeated, regular intervals between occurrences. Biologic rhythms can refer to both physical and psychological patterns.

Biomedical informatics The interprofessional science that deals with biomedical information's structure, acquisition, and use.

Bioterrorism The deliberate release of viruses, bacteria, or other microbes as weapons.

Bipolar disorder A mood disorder characterized by alternating depression and elation, with periods of normal mood in between. Formerly called *manic-depressive disorder*.

Birth room A single room in a hospital where a pregnant woman and her partner or other family members will stay for the labor, birth, recovery, and possibly the postpartum period.

Bisexual An individual who is attracted to members of both sexes.

Bisphosphonates Drugs used to treat osteoporosis that inhibit bone reabsorption by suppressing osteoclast activity.

Blackouts A form of amnesia about events that occurred during a drinking period. This is often seen in the early stages of alcoholism.

Bladder training Gradually increases the bladder capacity by increasing the intervals between voidings and resisting the urge to void.

Blame-free environment An environment in which healthcare providers can report errors or near misses without the fear of punishment.

Blended family A family formed after the death or divorce of a parent; may include stepparents on both sides, stepchildren, half-siblings.

Blepharism Spasms that cause the eye to blink continuously.

Blighted ovum One of the most common causes of miscarriage, it occurs when the egg has been fertilized and both the membrane and placenta have formed, but the embryo has not formed.

Blood flow The volume of blood transported in a vessel, in an organ, or throughout the entire circulation over a given period of time.

Blood pressure The force that blood exerts against the walls of the arteries as it is pumped from the heart.

Blood urea nitrogen (BUN) A measure of blood level of urea, the end product of protein metabolism.

Bloodborne pathogens Microorganisms carried in blood and body fluids that are capable of infecting other individuals with serious and difficult-to-treat viral infections.

Bloody show The pink-tinged secretions resulting from a small amount of blood loss from the exposed cervical capillaries during pregnancy.

Blunt trauma Trauma that occurs without any communication between the damaged tissues and the outside environment.

Body fluid Any fluid that is essential to homeostasis; water is the primary body fluid.

Body image The mental image of the physical self.

Body mass index (BMI) A method of comparing weight to height as an indirect measure of body fat.

Body substance isolation (BSI) System that employs generic infection control precautions for all patients, except those with the few airborne diseases.

Body surface area (BSA) The relationship between height and weight measured in square meters.

Body temperature The core or surface measurement of a patient's internal heat production and loss.

Bone marrow transplant The treatment of disease by infusing a patient with his or her own bone marrow or that of a healthy donor.

Borborygmus Hyperactive, high-pitched, tinkling, rushing, or growling bowel sounds heard in diarrhea or at the onset of bowel obstruction.

Borderline personality disorder (BPD) One of several personality disorders defined in the DSM-5, BPD is marked by unstable interpersonal relationships, self-image, affect, and impulsiveness.

Bouchard nodes Bony lumps in the middle joint of the digit.

Boundaries The invisible lines that define the amount and kind of contact allowable among members of a family and between the family and outside systems.

Boutonnière deformity A flexion deformity of the PIP joints with extension of the DIP joint.

Bowel incontinence The inability to voluntarily control the passage of fecal contents and intestinal gas through the anal sphincter. Also called *fecal incontinence*.

Brachytherapy Radiation treatment given by placing radioactive material directly in or near the target, which is often a tumor.

Bradycardia A heart rate in an adult of less than 60 bpm.

Bradydysrhythmia Abnormally slow rhythms.

Bradykinesia Slowed movements due to muscle rigidity.

Bradyphrenia Slowed thinking and a decreased ability to form thoughts, to plan, or to make decisions.

Bradypnea A respiratory rate of less than 10 breaths per minute in adults.

Brain death The cessation and irreversibility of all brain functions, including those of the brainstem.

Brainstem Contains the midbrain, pons, and medulla oblongata. Located between the cerebrum and spinal cord, the brainstem connects pathways between the higher and lower structures. Ten of the 12 pairs of cranial nerves originate in the brainstem.

Brainstorming A decision-making method in which group members meet and generate diverse ideas about the nature, cause, definition, or solution to a problem.

Braxton Hicks contractions Intermittent painless uterine contractions that may occur every 10–20 minutes and occur more frequently near the end of pregnancy.

Brazelton neonatal behavioral assessment scale A scale developed to assess a newborn's state changes, temperament, and individual behavioral patterns.

Breach of care See Breach of duty.

Breach of duty A deviation from the standard of care owed a patient. Also called *breach of care*.

Breakthrough pain A sudden flare or increase in pain despite comfort with or without baseline analgesia.

Breast Mammary gland.

Breast cancer The unregulated growth of abnormal cells in breast tissue.

Breathing exercises Techniques used to slow the breathing rate by focusing on taking regular and deep breaths from the diaphragm.

Brief psychotic disorder Rapid onset of at least one of the following psychotic symptoms: delusions, hallucinations, disorganized speech, or disorganized behavior. The episode lasts at least 1 day but less than 1 month, after which the person returns to the premorbid level of functioning.

Bronchial sounds Loud, high-pitched sounds heard over the trachea that are longer on exhalation than inhalation.

Bronchiectasis Chronic dilation of the bronchi and bronchioles.

Bronchiolitis A lower respiratory tract illness that occurs when an infecting agent (virus or bacterium) causes inflammation and obstruction of the small airways.

Bronchitis Inflammation of the mucous membranes of the bronchial tubes.

Bronchogenic carcinomas Tumors of the airway epithelium.

Bronchoscopy A procedure that allows direct visualization of the lungs by inserting a bronchoscope orally into the trachea and advancing it to the bronchi bifurcation.

Bronchovesicular sound The sound created as air moves within the bronchial tree.

Brown adipose tissue (BAT) A specific store of fat in newborn infants that appears dark brown due to enriched blood supply, dense cellular content, and abundant nerve endings.

Bruits Blowing sound sometimes heard due to restriction of blood flow through the vessels.

Buffers Substances that prevent major changes in pH by releasing hydrogen ions.

Bulimia nervosa (BN) A type of eating disorder characterized by an obsessive focus on weight and body size and cycles of binge eating followed by purging.

Bullying Any unwanted aggressive behavior committed against another who is not a sibling or dating partner.

Bureaucratic leader A leader who relies on the organization's rules, policies, and procedures to direct the group's work efforts.

Burn An injury resulting from exposure to heat, chemicals, radiation, or electric current.

Burn shock Hypovolemic shock resulting from the shift of a massive amount of fluid from the intracellular and intravascular compartments into the interstitium following burn injury. Also called *hypovolemic shock*.

Burnout A complex syndrome resulting from unmanaged stress that manifests as physical and emotional depletion, a negative attitude and self-concept, and feelings of helplessness and hopelessness.

G-8 Glossary

Cachexia Physical wasting from weight loss and loss of muscle mass due to the rapid growth and reproduction of cancer cells and their need for increased nutrients.

Caffeine A stimulant that increases the heart rate and acts as a diuretic.

Calcium oxalate A chemical compound from which kidney stones may form.

Calcium phosphate A chemical compound from which kidney stones may form.

Calculi Renal stones.

Cancellous bone The spongy tissue of bone.

Cancer A family of complex diseases with manifestations that vary according to body system and type of tumor cells.

Cancer pain Pain that may result from the direct effects of the cancerous disease and its treatment, or it may be unrelated to the disease and its treatment in individuals with cancer.

Candidiasis A common, opportunistic fungal infection in patients with AIDS.

Cannabis sativa The plant source of marijuana.

Caput succedaneum A localized, easily identifiable, soft area of the scalp, generally resulting from a long and difficult labor or vacuum extraction.

Carbohydrate One of the three major macronutrients primarily derived from plant foods. These foods contain simple and complex sugars, and starches.

Carcinogen A substance that causes cancer.

Carcinogenesis The production or origin of cancer.

Cardiac arrest The cessation of heart function that precedes biologic death.

Cardiac cycle One contraction and relaxation of the heart; a single heartbeat.

Cardiac index The cardiac output adjusted for the patient's body size or body surface area (BSA).

Cardiac markers Proteins released from necrotic heart muscle.

Cardiac output (CO) The amount of blood pumped by the ventricles into the pulmonary and systemic circulations in 1 minute.

Cardiac rehabilitation A medically supervised program designed to aid people with their recovery from heart attacks, heart surgeries, and percutaneous coronary interventions.

Cardiac reserve The heart's ability to respond to the body's changing need for cardiac output.

Cardiac tamponade Compression of the heart caused by collected blood or fluid in the pericardium.

Cardinal ligament Major ligament of the uterus containing the uterine artery and vein.

Cardinal movements A series of changes in position that allow the fetus to move through the birth canal. Also called *mechanisms of labor*.

Cardiogenic shock Shock that occurs when the heart's pumping ability is compromised to the point that it cannot maintain cardiac output and adequate tissue perfusion.

Cardiomyopathy Disease that affects the heart muscle's ability to pump effectively. Primary abnormality of the heart muscle that affects its structural or functional characteristics.

Cardiopulmonary resuscitation (CPR) A mechanical attempt to maintain tissue perfusion and oxygenation using oral resuscitation and external cardiac compressions.

Care coordination The means by which a multidisciplinary team works with a patient to ensure that the care received across the health-care continuum meets the patient's needs.

Care management model Planning, assessment, and coordination of health services to provide an integrated continuum of clinical services,

including medical care, health promotion, disease prevention, costs, and use of resources.

Care map Expected outcomes and care strategies developed through collaboration by the healthcare team. Also called a *critical pathway*.

Caring To feel interest, concern, and respect for a patient while demonstrating sensitivity, sincerity, honesty, and patience.

Caring for the dying The act of helping patients live as comfortably as possible until death and helping the patient's support individuals cope with death.

Carpal spasm Involuntary contraction of the hand and fingers due to decreased calcium levels.

Carphologia Involuntary, repeated lint picking.

Carrier Human or animal reservoir of a specific infectious agent that usually does not manifest any clinical signs of the disease.

Cartilage A type of flexible connective tissue found throughout the body.

Case management (CM) The coordination of patient care over time using the combination of health and social services necessary to meet the individual patient's needs.

Case managers Individuals who help manage the care of certain patient populations, including patients with chronic medical conditions, such as diabetes; patients recovering from acute conditions, such as those receiving joint replacement; and patients managing psychiatric disorders.

Case method A patient-centered method of managing care in which one nurse is assigned to, and is responsible for, the comprehensive care of a group of patients during an 8- or 12-hour shift.

Caseation necrosis A process in which tissue infected with *Mycobacterium tuberculosis* dies and forms a cheeselike center in the infectious bacilli.

Cast A rigid device applied to immobilize injured bones and promote healing.

Catabolism The breakdown of body proteins.

Cataract An opacification (clouding) of lens of the eye due to a breakdown of proteins within the lens.

Catatonica Unresponsiveness to the environment or others.

Catatonic excitement Includes hyperactivity and bizarre behavior and is a positive symptom of schizophrenia.

Catatonic inhibition Involves decreased activity level; limited speech; minimal self-care; and, at times, a trancelike state. Catatonic inhibition is a negative symptom of schizophrenia.

Cation Ion that carries a positive charge.

Cauda equina syndrome (CES) A condition that occurs when the nerve roots of the cauda equine are compressed. It may result in permanent neurologic impairment, including urinary incontinence and paralysis.

Causation To make a successful claim for malpractice, an injury must have occurred as a direct consequence of a nurse's or other healthcare professional's breach of duty.

Cavitation Formation of a cavity or bubble.

Celiac disease A chronic immune-mediated disorder of the small intestine in which the absorption of nutrients, particularly fats, is impaired. Also known as celiac sprue or nontropical sprue.

Cell cycle The four phases of cell growth and development.

Cell-mediated (cellular) immune response Direct or indirect inactivation of antigen by lymphocytes.

Cellulitis An acute bacterial infection of the dermis and underlying connective tissue. Cellulitis is characterized by red or lilac, tender, warm, edematous skin that may have an ill-defined, nonelevated border.

Central nervous system (CNS) One of two principal parts of the neurologic system, the central nervous system consists of the brain and the spinal cord.

Central nervous system (CNS) depressants A type of drug that acts to slow brain function, decreasing levels of alertness and awareness. CNS depressants include barbiturates, benzodiazepines, paraldehyde, meprobamate, and chloral hydrate.

Central pain 1. A type of pain related to a lesion in the brain that may spontaneously produce high-frequency bursts of impulses that are perceived as pain. 2. A type of pain caused by damage to the central nervous system that may manifest in constant pain, pain paroxysms, evoked pain, or allodynia. Patients may describe their pain as “pins and needles,” aching, or lacerating.

Centration Focusing only on one particular aspect of a situation or the ability to concentrate.

Cephalocaudal development Growth that proceeds in the direction from head to toe.

Cephalohematoma A collection of blood resulting from ruptured blood vessels between the surface of a cranial bone and the periosteal membrane. Also called an *entrapped hemorrhage*.

Cerebellum Located below the cerebrum and behind the brainstem, it coordinates stimuli from the cerebral cortex to provide precise timing for skeletal muscle coordination and smooth movements.

Cerebral palsy (CP) A group of chronic conditions affecting body movement, coordination, and posture that results from a nonprogressive abnormality of the immature brain.

Cerebral perfusion pressure (CPP) The pressure it takes for the heart to provide the brain with blood. It is calculated by finding the difference between arterial pressure and intracranial pressure. Normal CPP is 0–95 mmHg.

Cerebrum The largest portion of the brain, it is composed of gray matter and has two hemispheres divided into four regions or lobes.

Certification The credentialing process by which a nongovernmental agency or association recognizes the professional competence of an individual who has met the predetermined qualifications specified by the agency or association.

Cerumen Earwax.

Cervical cap A latex cup-shaped contraceptive device, used with spermicidal cream or jelly, that fits snugly over the cervix and is held in place by suction.

Cervical collar A device that stabilizes and maintains neutral alignment of the cervical spine; it is used with patients with potential or suspected cervical spine injury. Also called *C-collar*.

Cervical ripening The softening and effacing of the cervix.

Cervix The narrow neck of the uterus.

Cesarean birth The birth of an infant through an abdominal and uterine incision.

CFTR modulators A treatment for **cystic fibrosis** that attacks the cause of the problem—issues with the CFTR protein—rather than just CF’s clinical manifestations.

Chain of command The hierarchy of authority and responsibility within an organization.

Chancre A painless ulceration formed during the first stage of syphilis.

Change-of-shift report A type of handoff communication given to all nurses on the next shift.

Channel A medium used to convey messages.

Charcot-Marie-Tooth disease The most common inherited form of **peripheral neuropathy**, it is characterized by a slowly progressive degeneration of the muscles of the foot, lower leg, hand, and forearm. Symptoms usually present between adolescence and young adulthood.

Charismatic leader A rare type of leader who is characterized by a strong, emotional relationship between the leader and the group members.

Chart A formal, legal document that provides evidence of a patient’s care. Also called a *patient record* or a *clinical record*.

Charting The process of making an entry on a patient record. Also called *recording* or *documenting*.

Charting by exception (CBE) A documentation system in which only abnormal or significant findings or exceptions to norms are recorded.

CHCT A biopsy of thigh skeletal muscle tissue to determine sensitivity to caffeine and halothane.

Cheilosis Cracking of lips.

Chemical conjunctivitis An irritation of the conjunctiva by chemicals used to treat the eyes.

Chemical restraints Pharmacologic agents administered for the purpose of controlling hyperactive behavior in agitated patients.

Chemical thermogenesis The stimulation of heat production in the body through increased cellular metabolism. Also called *nonshivering thermogenesis* or *NST*.

Chemotaxis The movement of cells in response to a chemical stimulus.

Chemotherapy Cancer treatment involving the use of cytotoxic medications to decrease tumor size, adjunctive to surgery or radiation therapy; or to prevent or treat suspected metastases.

Chest physical therapy An **airway clearance technique** that involves clapping and **percussion**.

Chest x-ray Allows for two-dimensional visualization of the contents of the thoracic cavity.

Child abuse Any act or failure to act on the part of a parent or caretaker which results in the death, serious physical or emotional harm, sexual abuse, or exploitation of a child.

Child Health Insurance Program (CHIP) State and federal funded healthcare coverage for children under the age of 19 whose families earn more than the Medicaid limits but cannot afford to purchase private healthcare coverage.

Childhood traumatic grief A grief reaction that occurs when an important person in a child’s life dies as the result of a traumatic event or circumstances the child views as traumatic.

Childfree family A family without children.

Chlamydia A group of sexually transmitted infections caused by *Chlamydia trachomatis*.

Chloasma Brownish pigmentation over the bridge of the nose and the cheeks during pregnancy and in some women who are taking oral contraceptives. Also called *melasma gravidarum* or *mask of pregnancy*.

Cholangitis Duct inflammation.

Cholecystitis Inflammation of the gallbladder.

Cholelithiasis The formation of stones (*calculi* or *gallstones*) in the gallbladder or biliary duct system.

Chromosomes Tightly coiled strands of DNA within the nucleus that contain genetic information.

Chronic bronchitis A disorder of excessive bronchial mucous secretion.

Chronic fatigue Profound fatigue of long duration that is not improved by rest.

Chronic fatigue syndrome A complex disorder in which the patient experiences unrelenting fatigue and associated symptoms that are not alleviated by substantial rest and that cannot be otherwise explained for a period of 6 months or longer. Also called *myalgic encephalomyelitis*.

Chronic illness An alteration in health or function that lasts for an extended period of time, usually 6 months or longer, and often for the duration of the individual’s life.

Chronic infection An infection that develops slowly and persists for months or sometimes years.

Chronic intermittent colitis A recurrent form of ulcerative colitis characterized by insidious onset, few systemic manifestations, and attacks lasting 1–3 months that occur at intervals of months to years.

Chronic kidney disease A type of renal failure that progresses slowly with few symptoms until the kidneys are severely damaged and

unable to meet the excretory needs of the body. Also called *chronic renal failure*.

Chronic lymphocytic leukemia (CLL) A disorder characterized by the proliferation and accumulation of small, abnormal, mature lymphocytes in the bone marrow, peripheral blood, and body tissues.

Chronic myeloid leukemia (CML) A disorder characterized by abnormal proliferation of all bone marrow elements.

Chronic obstructive pulmonary disease (COPD) A specific progressive disorder that slowly alters the structures of the respiratory system over time, irreversibly affecting lung function.

Chronic pain Prolonged pain, usually lasting longer than 6 months. It is not always associated with an identifiable cause and is often unresponsive to conventional medical treatment.

Chronic pancreatitis An irreversible process characterized by chronic inflammation, fibrosis, and gradual destruction of functional pancreatic tissue.

Chronic traumatic encephalopathy (CTE) A form of dementia associated with a history of multiple concussions.

Chronic renal failure See Chronic kidney disease.

Chronic venous insufficiency (CVI) A disorder of inadequate venous return over a prolonged period of time.

Chvostek sign Facial grimacing caused by repeated contractions of the facial muscle. A test used to check for hypocalcemia.

Circadian rhythms Regular fluctuations in the body's physiologic processes occurring in a 24-hour cycle.

Circumcision A surgical procedure in which the prepuce, an epithelial layer covering the penis, is separated from the glans penis and excised. This procedure permits exposure of the glans for easier cleaning.

Cirrhosis The end stage of chronic liver disease. It is a progressive, irreversible disorder, eventually leading to liver failure.

Civil law The area of law that deals with the rights and duties of private persons or citizens and is most often enforced through the awarding of damages or compensation.

CK-MB A subset of CK enzyme specific to cardiac muscle. Elevated CK-MB is an indicator of myocardial infarction. Also called *MB-bands*.

Clang Repetition of rhyming words without apparent meaning.

Classism The oppression of groups of people based on their socioeconomic status.

Clean A state of medical asepsis in which almost all microorganisms are absent.

Client An individual who engages the advice or services of another person who is qualified to provide this service.

Clinical database The full extent of information about a patient, including the nursing health history, physical assessment, primary care provider's history and physical examination, results of laboratory and diagnostic tests, and material contributed by other health personnel.

Clinical decision support system A system that analyzes data and provides information about evidence-based practices. These systems can help improve patient safety and quality of care when used with sound nursing and medical judgment.

Clinical information system A software-based system that allows multiple disciplines to simultaneously access the patient's chart and record data that can be viewed and analyzed by a number of health-care providers in real time. These systems are designed to provide the most accurate and current information about the patient so that the best decisions concerning the care of that patient can be made.

Clinical pathway A standardized, evidence-based, multidisciplinary plan that outlines the expected care required for patients with common, predictable—usually medical—conditions.

Clonic phase Typically the second phase in a generalized or tonic-clonic seizure, characterized by alternating muscular contraction and relaxation.

Closed fracture A bone fracture in which the skin remains intact. Also called a *simple fracture*.

Closed questions Restrictive questions in an interview that require only a "yes" or "no" or short, specific answer.

Clotting Also known as **coagulation**, the process by which blood changes from liquid into a gel-like substance in order to stop bleeding from a damaged vessel.

Club drugs Substances popular among adolescents and young adults who frequent dance clubs and "raves." The most common is MDMA (methylenedioxymethamphetamine), better known as Ecstasy.

Coaching The process that encourages the development of individuals through personal interaction within an organization.

Coagulation Also known as **clotting**, the process by which blood changes from liquid into a gel-like substance for the purpose of forming a clot to stop bleeding from a damaged vessel.

Coagulation cascade A process that activates clotting factors, plasma proteins used in the formation of blood clots.

Coanalgesics Drugs that have analgesic properties, potentiate the effects of pain medications, relieve other discomforts, or reduce the side effects of analgesic drugs. Coanalgesics are especially effective at reducing neuropathic pain.

Coarctation of the aorta Narrowing or constriction in the descending aorta, often near the ductus arteriosus or left subclavian artery, which obstructs the systemic blood outflow.

Cobb angle A technique to estimate the degree of curvature of the spine using lines drawn from the vertebrae at the upper and lower limits of the curve that tilt most dramatically toward the apex of the curve.

Cocaine A powerful stimulant of natural origin that acts at the nerve terminals to prevent the reuptake of dopamine and norepinephrine, which in turn results in vasoconstriction, tachycardia, and hypertension.

Code of ethics A general guide for a profession's membership and a social contract with the public that it serves.

Codependence A cluster of maladaptive behaviors exhibited by significant others of a substance-abusing individual that serves to enable and protect the abuse at the expense of living a full and satisfying life.

Cognition The complex set of mental activities through which individuals acquire, process, store, retrieve, and apply information.

Cognitive appraisal The process of appraising, sorting, assessing, categorizing, evaluating, and framing the significance of an event or stressor with respect to an individual's own well-being.

Cognitive-behavioral therapy (CBT) The use of cognitive techniques and behavior modification to change detrimental beliefs and thought patterns.

Cognitive development The manner in which people learn to think, reason, and use language.

Cognitive domain The learning domain that includes the six intellectual abilities and thinking processes: knowing, comprehending, applying, analysis, synthesis, and evaluation. Also called the *thinking domain*.

Cognitive skills Intellectual skills or thought processes that include problem solving, decision making, critical thinking, and creativity.

Cognitive symptoms Cognitive symptoms of schizophrenia include deficits in memory, attention, language, visual-spatial awareness, social and emotional perception, and intellectual and executive function.

Cognitive theory A learning theory that recognizes the developmental level of learners and acknowledges the learner's motivation and environment. Also called *cognitivism*.

Coitus interruptus A method of contraception in which the man withdraws from the woman's vagina when he feels that ejaculation is impending.

Cold zone When a disaster occurs, this zone, located outside the warm zone, is where decontaminated victims are triaged and treated. Also called the *green zone* or the *support zone*.

Colectomy Surgical resection and removal of the colon.

Collaboration Two or more people working toward a common goal.

Collaborative intervention The actions a nurse carries out in collaboration with other healthcare team members, such as physical therapists, social workers, dietitians, and physicians.

Collagen A whitish protein substance that adds tensile strength to a wound.

Collateral channels Small blood vessels that develop to connect small arteries. Also called *collateral circulation*.

Colloid osmotic pressure A pulling force exerted by colloids that helps maintain the water content of blood by pulling water from the interstitial space into the vascular compartment. Also called *oncotic pressure*.

Colloids Substances such as large protein molecules that do not readily dissolve into true solutions.

Colon cancer Cancer of the third segment of the large bowel that may or may not include the anus.

Colonization The process by which strains of microorganisms become resident flora, capable of growing and multiplying.

Colorectal cancer Cancer of both the colon and rectum.

Colostomy A surgical opening into the colon.

Colostrum The initial milk that begins to be secreted during midpregnancy and that is immediately available to the baby at birth.

Column plan A nursing care plan that uses columns to categorize data for each phase of the nursing process. This type of care plan may include four columns: (1) nursing diagnoses, (2) goals/desired outcomes, (3) nursing interventions, and (4) evaluation. Some include only three columns.

Combined oral contraceptives (COCs) A safe, highly effective contraceptive pill combining estrogen and progesterin. Also called *birth control pills*.

Comfort To ease the grief or trouble of others; to give hope.

Commitment The state or an instance of being obligated or emotionally impelled.

Communicable disease An illness that is transmitted directly from one person or animal to another by contact with body fluids, or that is indirectly transmitted by contact with contaminated objects or vectors.

Communication The exchange of information, feelings, thoughts, and ideals through verbal or other techniques.

Communication deviance Communication patterns that are distracting and confusing to listeners who are trying to share a common focus or meaning with a speaker. Communication deviance has been identified as a social-environmental trigger for schizophrenia symptoms.

Communicator style The manner in which an individual communicates; includes the way the individual interacts with others.

Community-based care Care that focuses on the political, social, institutional, and physical environments of the patient.

Community Emergency Response Team (CERT) program A Federal Emergency Management Agency–organized program that prepares participants to safely assist themselves, their families, and their neighbors in case of a disaster.

Comorbidity The presence of two or more disease processes.

Compartment syndrome A condition in which the tissue pressure in a muscle compartment exceeds the microvascular pressure, interrupting cellular perfusion.

Compassion An awareness of and concern for other individuals' suffering.

Competence Possessing the knowledge and skills necessary to perform one's job appropriately and safely.

Complementary health approaches (also referred to as alternative therapies) Any of the diverse array of practices, therapies, and supplements that are not considered part of conventional or traditional medicine that are used in addition to conventional treatments.

Complete spinal cord injury An injury that involves a total loss of all sensory and motor function below the level of the injury; usually the damage is irreversible.

Compliance 1. The relationship between the volume of the intracranial components and intracranial pressure. 2. The amount of distention or expansion the ventricles can achieve to increase stroke volume. 3. The extent to which an individual's behavior coincides with medical or health advice.

Complicated grief A form of grief in which the individual's strategies to cope with a loss are maladaptive. Also called *prolonged grief disorder (PGD)*.

Compression A condition that occurs when a vertical force is applied to the spinal column, such as occurs by falling and landing on the feet or buttocks or diving into shallow water.

Compromised host An individual who is at increased risk of infection.

Compulsion A repetitive behavior or mental activity used in response to obsessive thoughts that helps the individual lower his or her anxiety level.

Compulsivity One of the six trait domains associated with personality disorders that is distinguished by extreme inflexibility in a quest for perfection, in relation to both the individual's own actions and others' behaviors.

Computer vision syndrome The most common sequela of computer use. Symptoms include eye fatigue, headaches, blurred vision, dry eyes, and changes in color perception. Also called *eye strain*.

Concept map A visual representation of a nursing plan of care in a patterned diagram with data and ideas. Various shapes and colors are used to show relationships and connections in combination with lines or arrows.

Concrete thinking A type of thinking characterized by a focus on facts and details coupled with an inability to generalize or think abstractly.

Concurrent audit An evaluation of the adequacy of the nursing care a patient is receiving and a determination of whether desired outcomes are being met while the individual is still undergoing care at the healthcare facility.

Concussion Mild **traumatic brain injury**.

Condom A sheath of synthetic material that covers the penis to prevent conception or disease.

Conduction The process of heat transfer through physical contact of one surface with another surface.

Confabulation Making up information to fill memory gaps; used as a defensive mechanism to protect the person's attempt to protect self-esteem when confronted with memory loss.

Confidentiality The assurance the patient has that private information will not be disclosed without the patient's consent.

Conflict A situation that occurs when an agreement cannot be reached with regard to significant issues and concerns or when emotional opposition creates discord within an individual or among individuals, groups, or organizations.

Conflict competence Purposeful development of cognitive, behavioral, and emotional skills that assist individuals in preventing and reducing conflict.

Confusion An alteration in cognition that makes it difficult to think clearly, focus attention, or make decisions.

Confusion assessment method (CAM) A two-part test that differentiates between delirium and dementia. It is specifically designed to account for and control ageism.

Congenital cataracts A type of cataract that may appear in a child at birth or in childhood, usually in both eyes.

Congenital glaucoma A primary form of **glaucoma** caused by an abnormal development in the ocular drainage system that is sometimes diagnosed at birth but is usually diagnosed within the first year.

G-12 Glossary

When diagnosed within the first year, it is often referred to as **infantile glaucoma**. When diagnosed after age 3, it may be referred to as **juvenile glaucoma**.

Congenital heart defect A defect of the heart or great vessels that is present at birth.

Congruent communication Communication in which the verbal and nonverbal aspects of the message match.

Conjugate vera The true conjugate, which extends from the middle of the sacral promontory to the middle of the pubic crest.

Conjunctiva The thin, transparent membrane that covers the anterior surface of the eye and lines the inner surfaces of the eyelids.

Conjunctivitis Inflammation of the conjunctiva. The most common eye disease, conjunctivitis is usually caused by a bacterial or viral infection.

Connective tissue Tissue made of fiber that forms the framework for support of the body's tissue and organs.

Consciousness A condition in which the individual is aware of self and environment and is able to respond appropriately to stimuli. Full consciousness requires both normal arousal and full cognition.

Consequence-based (teleologic) theories Theories that look to the outcomes (consequences) of an action in judging whether that action is right or wrong.

Conservation The concept that matter is not changed when its form is altered.

Consolidation Solidification of damaged cells and tissue during immune response to inflammation, specifically in the lungs.

Constant fever A condition that occurs when the body temperature fluctuates minimally but always remains above normal.

Constipation Fewer than three bowel movements per week or the difficult passage of stools.

Constructivism A collection of theories with the common thread of individuals actively constructing knowledge in order to solve realistic problems, often in collaboration with others.

Consumer An individual, a group of people, or a community that uses a service or commodity.

Consumer-driven healthcare plan (CDHP) A type of employer-sponsored coverage that combines a private insurance plan with a Health Savings Account (HSA) or Health Reimbursement Account (HRA).

Contact dermatitis An inflammation of the skin that occurs in response to direct contact with an allergen or irritant.

Contact precautions Used for patients who are known to have or suspected of having serious illnesses that are easily transmitted by direct contact with the patient or by contact with items in the environment, such as *Shigella*.

Contingency contracts A reinforcement process. Contingency contracts operate by "if-then" rules. If the patient performs a targeted response, such as abstinence from the addictive behavior (gambling, drug use, cutting, and so on), then the patient receives desired reinforcers.

Contingency planning The process of identifying and managing unplanned and unexpected events that interfere with getting work done efficiently, effectively, and in a timely manner.

Continuance commitment The awareness of costs associated with leaving a profession that inhibit an individual from leaving that profession. Considered the weakest type of commitment to a profession.

Continuous bladder irrigation (CBI) A method used to prevent the formation of blood clots.

Continuous positive airway pressure (CPAP) Mechanical ventilation that applies positive pressure to the airways of a patient who is breathing spontaneously. Breathing is patient triggered and pressure controlled. CPAP is used to help maintain open airways and alveoli, decreasing the work of breathing.

Continuous quality improvement (CQI) A structured organizational process for involving personnel in planning and executing a continu-

ous flow of improvements to provide quality healthcare that meets or exceeds expectations.

Continuous renal replacement therapy (CRRT) A form of dialysis in which blood is continuously circulated through a highly porous hemofilter from artery to vein or vein to vein.

Contractility The inherent capability of the cardiac muscle fibers to shorten.

Contraction stress test (CST) A method of evaluating the respiratory function (oxygen and carbon dioxide exchange) of a placenta.

Contracture Permanent shortening of connective tissue.

Contralateral deficit Loss or impairment of sensorimotor functions on the side of the body opposite the side of the brain that is damaged by stroke.

Contrecoup injury This injury occurs when the brain strikes the side of the skull opposite to the side of impact.

Controlled Substance Act (CSA) A federal law that requires drugs to be classified based on the substance's medical use, potential for abuse, and safety risks.

Controlling The managerial process of comparing actual results with projected results, similar to the evaluation step in the nursing process. Controlling includes establishing performance standards, determining how to measure performance and creating the tools that will permit consistent measurement, evaluating performance, and providing feedback.

Convection The process of heat transfer through the fluid motion of air or water across the skin.

Convergence The medial rotation of the eyeballs so that each is directed toward the viewed object.

Co-occurring disorders Concurrent diagnosis of a substance use disorder and a psychiatric disorder. One disorder can precede and cause the other, such as the theorized relationship between alcoholism and depression.

Cooperative play The stage of play in which children work together to contribute to a unified whole, such as forming a sports team or dancing in an ensemble.

Copayment The set payment owed by an insured individual at the time a covered service is rendered.

Coping A dynamic process through which an individual applies cognitive and behavioral measures to handle internal and external demands that are perceived by the individual as exceeding available resources.

Cor pulmonale Right-sided heart failure.

Corneal abrasion Disruption of the superficial epithelium of the cornea.

Corneal reflex Closure of eyelids (blinking) due to corneal irritation.

Cornu The elongated portion of the uterus where the fallopian tubes enter.

Coronary artery bypass grafting (CABG) A procedure in which a section of a vein or artery is used to create a connection, or bypass, between the aorta and the blocked coronary artery beyond the obstruction.

Coronary artery disease (CAD) The most common type of heart disease, CAD is caused by impaired blood flow to the myocardium.

Coronary circulation A network of vessels that supply the heart muscle.

Corpus The upper triangular portion of the uterus. Also called the *uterine body*.

Corpus luteum A small yellow body that develops within a ruptured ovarian follicle.

Corrective action The steps taken to overcome a job performance problem.

Coryza Inflammation of the mucous membranes lining the nose, usually associated with nasal discharge.

Countershock phase The second part of an alarm reaction during which the sympathetic nervous system stimulation triggers the body's defenses.

Coup injury An injury that occurs when the brain strikes the same side of the skull as the side of impact.

Coup-contrecoup injury In this type of injury, the brain strikes the coup side, then bounces back and strikes the contrecoup side, resulting in contusions on both sides of the brain.

Couplet Two premature ventricular contractions in a row.

Couvade In some cultures, the man's observance of certain rituals and taboos to signify the transition to fatherhood.

Covert conflict Conflict that is avoided, ignored, or not discussed openly.

Crack A form of freebase cocaine that is made of baking soda, water, and cocaine mixed into a paste and microwaved to form a rock.

Crackles High-pitched popping sounds heard on inspiration due to fluid associated with or resulting from inflammation, or exudates, within the lung fields, or localized atelectasis.

Creatinine clearance A test that uses 24-hour urine and serum creatinine levels to determine the glomerular filtration rate; a sensitive indicator of renal function.

Creatine kinase (CK) An enzyme important for cellular function that is found principally in cardiac and skeletal muscle and the brain.

Creativity The ability to find or create a unique solution to a unique problem when traditional interventions are not effective.

Creativity techniques Strategies, such as brainstorming sessions, that use the creative potential of the group to generate a large number of possible options quickly.

Credentialing The formal identification of professionals who meet predetermined standards of professional skill or competence.

Credibility The quality of being truthful, trustworthy, and reliable.

Crepitation A grating or cracking sound.

Crime An act prohibited by statute or by common law principles.

Criminal law The area of law that deals with conduct that is harmful to another individual or to society as a whole and that may be punishable by fines or imprisonment.

Crisis An event or circumstance that overwhelms an individual's inherent ability to resolve, manage, or process the event or circumstance.

Crisis counseling A meeting that focuses on brief solutions, focused interventions, and supportive care during or after a crisis. It also considers the individual's physical vulnerability and degree of emotional stability.

Crisis intervention An emergent approach to care that is intended to assist patients with recognizing a crisis situation, and identifying and implementing an immediate, short-term solution.

Crisis intervention centers Organizations that provide telephone counseling for patients in crisis. Some organizations also provide consultation through email and online chatting.

Critical pathway Expected outcomes and care strategies developed through collaboration by the healthcare team. Also called a *case map*.

Critical thinking All or part of the process of questioning, analysis, synthesis, interpretation, inference, inductive and deductive reasoning, intuition, application, and creativity.

Crohn disease A chronic, relapsing inflammatory bowel disorder affecting the gastrointestinal tract. Also known as *regional enteritis*.

Cross-dressing Occurs when an individual of one gender (typically male) dresses in clothing specific to the opposite gender.

Crowning During birth, the appearance of the newborn's head or presenting fetal part at the vaginal orifice.

Crystalloids Salts that dissolve readily into true solutions.

Cultural deprivation A lack of culturally assistive, supportive, or facilitative acts.

Cultural groups Racial, ethnic, religious, or social groups with specific group behaviors and characteristics that are learned and shared, including language, customs, beliefs, and values.

Cultural humility The recognition that a healthcare provider's personal cultural values are not superior to the cultural values of others, thus preventing an abuse of power.

Cultural values Preferred ways of behaving or thinking that are sustained over time and used to govern a cultural group's actions and decisions.

Culture The patterns of behavior and thinking that people living in social groups learn, develop, and share.

Cultures Laboratory cultivations used to identify probable microorganisms by their characteristics, such as shape, growth patterns, and Gram-staining qualities.

Curling ulcers Acute ulcerations of the stomach or duodenum that form following a burn injury.

Cushing syndrome A disorder resulting from too much cortisol in the body. It can develop in individuals who take too much exogenous glucocorticosteroid for asthma or other disorders, or it can develop as a result of the overproduction of endogenous cortisol due to a pituitary or adrenal tumor.

Cyanosis Gray to blue or purple skin color caused by deoxygenated hemoglobin.

Cyber-bullying Aggression or bullying that occurs through the use of technology (e.g., social media, texting, or email).

Cycle of violence Violence that occurs with a patterned frequency, usually in three phases: initial tension due to communication failures, an abusive incident, and a honeymoon stage in which the aggressor may show love and affection. Cycle of violence may also refer to violence that spans multiple generations in a family.

Cyclothymic disorder A type of bipolar disorder characterized by chronic, fluctuating mood disturbances involving numerous periods of hypomanic symptoms and numerous periods of depressive symptoms.

Cystic fibrosis (CF) An inherited disorder that affects the secretory glands, particularly the glands that are responsible for secreting mucus, digestive enzymes, and sweat.

Cystic fibrosis transmembrane conductance regulator (CFTR) protein. A protein that is central to the movement of chloride into and out of the body cells.

Cystitis Inflammation of the urinary bladder.

Cystoscopy Endoscopy of the urinary tract. Also called *catheterization*.

Cytokines Proteins that carry messages for immune system function.

Damages Compensation sufficient to restore the plaintiff to his or her original position, so far as is financially possible.

Dashboard An interface that gathers, organizes, and displays a health-care facility's key performance indicators in an easy-to-read format, often with charts or graphs.

Dashboard knee Tearing of the posterior cruciate ligament or any knee injury resulting from an individual's knee slamming into the dashboard or back of a seat during a motor vehicle collision.

Database A compilation of all information about a patient, including the nursing health history, physical assessment, primary care provider's history, physical examination, and test results.

Date rape A term used when dating violence takes the form of rape.

Dating violence A type of intimate partner abuse; this type occurs most often in relationships among youth.

Dawn phenomenon A rise in blood glucose between 4 a.m. and 8 a.m. that is not a response to hypoglycemia.

Dead space Areas of the lung that are ventilated but not perfused.

Death anxiety Worry or fear related to death or dying.

Debridement The process of removing painful or necrotic material, including all loose tissue, wound debris, and dead tissue, from a wound.

Decelerations The periodic decreases in fetal heart rate from the normal baseline.

Decerebrate posturing An abnormal posture adopted by an unconscious individual that indicates deteriorating brain function. It is characterized by an extended neck; clenched jaw; arms pronated, extended, and close to the sides; legs extended and feet plantar flexed.

Decibels (dB) Units of loudness.

Decision tree A graphic model that visually represents the choices, outcomes, and risks to be anticipated.

Declarative memory Memory that is related to people and facts, is consciously accessible, and can be verbally expressed.

Decode The process of relating the message perceived to the receiver's storehouse of knowledge and experience and sorting out the meaning of the message.

Decompensation Loss of effective compensation.

Decorticate posturing An abnormal posture adopted by an unconscious individual that indicates deteriorating brain function. It is characterized by the upper arms kept close to the sides; the elbows, wrists, and fingers flexed; the legs extended and internally rotated; and the feet plantar flexed.

Deductible A set annual cost for healthcare paid by an individual or family participating in a health insurance plan.

Deductive reasoning A "top-down" method of logical thinking that starts with a conclusion and analyzes the situation for valid, significant cues. One of two methods of logical thinking that are used to determine if decisions are reasonable.

Deep brain stimulation (DBS) A procedure in which a neurostimulator is implanted into the individual to send electrical signals to one of three brain regions—the subthalamic nucleus, the globus pallidus, or the thalamus—in order to reduce symptoms of Parkinson disease.

Deep venous thrombosis (DVT) A blood clot that forms along the intimal lining of a large vein, usually in a leg.

Defecation The expulsion of feces from the anus and rectum.

Defense mechanism See Adaptive mechanisms.

Defibrillation An emergency procedure that delivers an electrical shock to stop ventricular fibrillation and return to a rhythm that promotes cardiac output sufficient to sustain life.

Deficiency A term used to describe when intake of a nutrient is less than recommended.

Defining characteristics The cluster of signs and symptoms that indicate the presence of a particular diagnostic label.

Deformation The alteration of the spinal cord and soft tissues caused by abnormal movement.

Dehiscence An unintended separation of wound margins due to incomplete healing.

Dehydration A condition that occurs when a body does not take in as much water as it loses or lacks sufficient reserves to maintain proper function.

Delayed ejaculation Once called **male orgasmic disorder**, involves extreme difficulty ejaculating, despite the ability to maintain an erection for long periods (in some cases, an hour or more).

Delayed union The delayed healing of bones beyond the expected time period.

Delegate An individual who assumes responsibility for the actual performance of an assigned task or procedure.

Delegation The transfer of responsibility and authority for completing an activity to a qualified individual.

Delegator An individual who assigns a task to another individual to perform, but retains accountability for the outcome.

Delirium An acute cognitive disorder that affects functional independence.

Delirium tremens (DTs) A medical emergency usually occurring 3–5 days following alcohol withdrawal and lasting 2–3 days. Characterized by paranoia, disorientation, delusions, visual hallucinations, elevated vital signs, vomiting, diarrhea, and diaphoresis. Also known as *alcohol withdrawal delirium*.

Delusions False ideas or beliefs not based in reality.

Dementia The progressive, irreversible loss of cognitive function.

Democratic leader A leader who assumes that individuals are internally motivated, are capable of making decisions, and value independence. Democratic leaders typically provide constructive feedback, offer information, make suggestions, and ask questions to gain information or to help group members grow in their ability to make decisions.

Demography The study of population, including statistics about distribution by age and place of residence, mortality, and morbidity.

Demyelination A condition in which cells of the immune system, such as lymphocytes and macrophages, cross the blood–brain barrier and attack and destroy the myelin sheath.

Denominations Groups of members that adhere to the same practices and beliefs.

Dental caries Cavities.

Deoxyribonucleic acid (DNA) One of two types of nucleic acid made by cells, DNA contains the genetic instructions for the development and functioning of human beings.

Dependence A physiologic need for a substance that the patient cannot control, and which results in withdrawal symptoms if the substance is withheld.

Dependent intervention Activities carried out under a physician's orders or supervision, or according to specified routines or protocols.

Dependent personality disorder (DPD) One of several personality disorders defined in the DSM-5, it is marked by a pervasive, excessive, and unrealistic need to be cared for; fear of separation; lack of self-confidence; an inability to make decisions; and an inability to function independently.

Depersonalization A feeling of strangeness or unreality about the physical self.

Depolarization 1. The rapid inflow of sodium ions, causing an electrical change in which the inside of a cell becomes positive in relation to the outside. 2. The phase in which the heart contracts as a result of ion channel functions.

Depo-Provera A long-acting progesterone that provides highly effective birth control for 3 months when given as a single injection.

Depression A disorder characterized by a sad or despondent mood or loss of interest in usual activities.

Depressive disorder with peripartum onset See Postpartum depression.

Derealization A feeling of disconnection from an individual's own body or the environment.

Dermatome An area of skin innervated by the cutaneous branch of one spinal nerve.

Dermis The second layer of skin, which is made of a flexible connective tissue. It is richly supplied with blood cells, nerve fibers, and lymphatic vessels, as well as most of the hair follicles, sebaceous glands, and sweat glands.

Desaturated blood Blood that is low in oxygen as a result of oxygenated and deoxygenated blood mixing due to a congenital heart defect.

Desire phase The first phase of the sexual response cycle is the arousal of sexual interest by means of real or symbolic stimuli.

Detachment One of the six trait domains associated with personality disorders that is broken down into withdrawal, intimacy avoidance, anhedonia, and restricted affectivity.

Detrusor muscle The smooth muscle layers of the bladder wall, the detrusor muscle allows the bladder to expand as it fills with urine and contract as it releases urine during voiding.

Development An increase in the complexity and function of skill progression, the individual's capacity and skill to adapt to the environment. Related to growth.

Developmental disability Any of a variety of chronic conditions characterized by mental and/or physical impairment.

Developmental stage A level of achievement for a particular segment of an individual's life.

Developmental task A skill or behavior pattern learned during stages of development.

Device integration Real-time, accurate data is recorded in the patient's chart directly from a device (e.g., blood pressure monitor). Device integration allows the nurse to more quickly analyze and interpret that data and make adjustments to the plan of care based on the most current information.

Diabetes mellitus Group of chronic disorders of the endocrine pancreas, all categorized under a broad diagnostic label. The condition is characterized by inappropriate hyperglycemia caused by a relative or absolute deficiency of insulin or by a cellular resistance to the action of insulin. Also called *diabetes*.

Diabetic ketoacidosis (DKA) A form of metabolic acidosis that develops when there is an absolute deficiency of insulin and an increase in the insulin counterregulatory hormones. It may also be induced by stress in an individual with type 1 diabetes.

Diabetic nephropathy Disease of the kidneys in patients with diabetes that is characterized by the presence of albumin in the urine, hypertension, edema, and progressive renal insufficiency.

Diabetic neuropathy A disorder of the peripheral nerves and the autonomic nervous system in patients with diabetes, which manifests in one or more of the following: sensory and motor impairment, muscle weakness and pain, cranial nerve disorders, impaired vasomotor function, impaired gastrointestinal function, and impaired genitourinary function.

Diabetic retinopathy The collective name for the changes in the retina that occur in the person with diabetes. The retinal capillary structure undergoes alterations in blood flow, leading to retinal ischemia and a breakdown in the blood-retinal barrier.

Diagnosis-related groups (DRGs) A system of price control regulation that classifies patient illnesses based on diagnoses and pays hospitals a predetermined sum for each specific diagnosis regardless of the actual cost of services, the length of stay, or the acuity or complexity of the patient's illness.

Diagnostic label Standardized NANDA names for nursing diagnoses.

Diagonal conjugate Distance from the lower posterior border of the symphysis pubis to the sacral promontory.

Dialysate Dialysis solution.

Dialysis A process by which fluids and molecules pass through a semipermeable membrane from an area of higher solute concentration to one of lower solute concentration according to the rules of osmosis. Dialysis is used to remove excess fluid and metabolic waste products in renal failure.

Diaphragm A flexible disc that covers the cervix to prevent conception.

Diaphysis The shaft of a bone.

Diarrhea The passage of liquid feces and an increased frequency of defecation.

Diastasis recti abdominis A separation of the abdominal muscle.

Diastole The phase of ventricular relaxation between heartbeats.

Diastolic blood pressure The minimum pressure within the arteries during diastole.

Diathermy Treatment with heat generated by high-frequency electrical currents.

Diencephalon Area of the brain consisting of the thalamus (sometimes called the dorsal thalamus), hypothalamus, epithalamus, and subthalamus.

Diet recall Patient history of intake over a specified period of time.

Dietary Reference Intakes (DRIs) A standardized, recommended nutrient intake to support a healthy diet often provided by health organizations.

Differentiated practice A system in which each nurse's educational preparation and skill sets are evaluated and used to determine how he or she will be best used.

Differentiation A process occurring over many cell cycles that allows cells to specialize in certain tasks.

Diffuse axonal injury An injury that occurs because of a rotational deceleration that is dramatic enough to cause damage to the brain's white matter in the form of widespread disruption of axon fibers and myelin sheaths.

Diffusion The continual intermingling of molecules in liquids, gases, or solids brought about by the random movement of the molecules.

Digestion The conversion of food by means of its mechanical and chemical breakdown into absorbable substances in the gastrointestinal tract.

Digital rectal examination (DRE) An examination to detect for abnormalities in the rectum that can be detected through palpation.

Dihydrotestosterone (DHT) The androgen that mediates prostatic growth at all ages; formed in the prostate from testosterone.

Dilated cardiomyopathy The most common form of cardiomyopathy, it is characterized by the dilation of the heart chambers and impaired ventricular contraction.

Directing The managerial process of effectively motivating, communicating, and delegating tasks in order to complete an organization's work.

Directive interview A highly structured interview that elicits specific health information.

Dirty In medical asepsis, a term used to indicate that microorganisms are likely to be present.

Disaster An event that occurs with little or no warning in which available personnel and emergency services are initially overwhelmed and a serious threat to life, public health, and the environment is posed.

Discharge planning A plan of care that prepares the patient for discharge, including training in any necessary health skills.

Discipline A method of teaching children the rules for how to behave in society and what is expected in different circumstances.

Discoid lesions Raised, scaly, circular lesions with an erythematous rim.

Discovery The legal process of obtaining information before a trial.

Discrimination The differential treatment of individuals or groups, based on categories such as race, age, weight, gender, or social class, that occurs when an individual acts on prejudice and denies other people one or more of their fundamental rights.

Discussion An informal oral consideration of a subject by two or more healthcare personnel to identify a problem or establish strategies to resolve a problem.

Disease A detectable alteration in body function resulting from infection by microorganisms that causes a reduction of capacities or a shortening of the normal lifespan. Also called *pathogenesis*.

Disease surveillance Monitoring patterns of disease occurrence from cases of infections and communicable diseases reported by healthcare workers to state officials.

Diseases of adaptation Stress-related illnesses, such as peptic ulcers and hypertension.

Disenfranchised grief Grief that occurs when an individual is unable to acknowledge a loss to other persons. Also called *ambiguous loss*.

Disinfectants Agents that destroy pathogens other than spores.

Disinhibition One of the six trait domains associated with personality disorders that is noted for the presence of irresponsibility, impulsivity, and risk taking.

Disc Fluid-filled “shock absorber” that holds together and insulates the vertebrae. Also called *spinal disc*.

Discectomy The removal of all or part of the nucleus pulposus of an intervertebral disc.

Dismissal Termination of employment.

Disorganized behavior The inability to start or finish goal-oriented activities to a degree that it interferes with an individual’s ability to lead a normal life.

Disorganized thinking Difficulty logically connecting thoughts, leading to garbled speech.

Dissatisfaction problems Issues that arise from unmet sexual needs and expectations.

Disseminated intravascular coagulation (DIC) A disruption of hemostasis characterized by widespread intravascular clotting and bleeding. It may be acute and life threatening, or it may be relatively mild.

Distracted driving The act of driving a motor vehicle while doing any activity that takes attention away from the road. Activities include texting, talking on the phone, eating, drinking, reading a map, talking to passengers, looking at a GPS, and adjusting the radio.

Distress A stress that is associated with inadequacy, insecurity, and loss.

Distributive shock Shock that results from widespread vasodilation and decreased peripheral resistance. Also called *vasogenic shock*.

Diuresis The production and excretion of abnormally large amounts of urine. Also called *polyuria*.

Diuretics Pharmacologic agents that increase urine formation and secretion.

Diversity The unique variations among and between individuals, variations that are informed by genetics and cultural background, but that are refined by experience and personal choice.

Diverticula Saclike projections of mucosa through the muscular layer of the wall of a canal or organ, e.g., the bladder wall, colon, or large intestine.

Documenting The process of making an entry on a patient record. Also called *recording* or *charting*.

Doll’s eye reflex An oculomotor response in which the eyes move in opposite direction as head turns to the side. Also called the **oculoccephalic reflex**.

Domestic partner An unmarried partner of the same or opposite sex.

Do-not-intubate (DNI) order Usually written by the physician for the patient who has a terminal illness or is near death, this order is usually based on the wishes of the patient and family that no lifesaving measures be provided once the patient stops breathing.

Do-not-resuscitate (DNR) order Usually written by the physician for the patient who has a terminal illness or is near death, this order is usually based on the wishes of the patient and family that no cardiopulmonary resuscitation be performed for respiratory or cardiac arrest. Also called a *no-code order*.

Dopamine A brain neurotransmitter that regulates voluntary movement, reward-seeking behavior, memory and learning, attention, sleep, affect, and many other functions.

Dormant Temporarily inactive but not dead.

Double-bind theory The theory that schizophrenia symptoms are partially an expression of contradictory family interactions.

Double depression A term used to describe a situation in which an individual experiences dysthymic disorder in combination with major depressive disorder.

Doula A paid caregiver who has typically received special training and may even be certified in caring for laboring women.

Down syndrome A developmental disorder that occurs when an individual is born with an extra full or partial chromosome. Down syndrome is associated with intellectual disability and a wide variety of physical impairments that can range from mild to severe.

Dramatic play The stage of play in which individuals use props to act out the drama of human life.

Dressler syndrome A symptom complex characterized by fever and chest pain that may develop days to weeks after an AMI. It is thought to be a hypersensitivity response to necrotic tissue or an autoimmune disorder.

Droplet nuclei Residue of evaporated droplets emitted by an infected host; can remain in the air for long periods of time.

Droplet precautions Used for patients who are known to have or suspected of having serious illnesses transmitted by particle droplets larger than 5 microns, such as pertussis or pneumonia.

Dual diagnosis Term used to refer to concurrent diagnoses of a psychiatric disorder and a substance use disorder.

Dubowitz tool A tool for assessing newborns that includes neuromuscular tone assessments, such as head lag, ventral suspension, and leg recoil.

Dullness A thudlike sound produced by dense tissue such as the liver, spleen, or heart.

Duodenal ulcer A peptic ulcer occurring in the duodenum.

Durable power of attorney A legal document that can delegate the authority to make health, financial, and/or legal decisions on an individual’s behalf.

Durable power of attorney for healthcare A legal designation of another individual, usually a family member, significant other, or close personal friend, to make healthcare decisions on an individual’s behalf.

Duration 1. The length of a sound. 2. The length of time from the beginning of a contraction to the completion of that same contraction.

Duty A legally enforceable obligation to conform to a particular standard of conduct that is owed to the patient.

Dwarfism Excessively short stature caused by insufficient growth hormone, typically resulting from a genetic abnormality.

Dysfunctional uterine bleeding (DUB) Vaginal bleeding that is usually painless but abnormal in amount, duration, or time of occurrence. Also called *abnormal uterine bleeding*.

Dysmenorrhea Painful menstruation.

Dyspareunia Painful intercourse.

Dysphagia Difficulty swallowing.

Dysplasia A loss of DNA control over differentiation occurring in response to adverse conditions.

Dyspnea Shortness of breath or difficulty breathing that is uncomfortable or painful; or when breathing is insufficient to meet oxygen demand.

Dysrhythmia Abnormal heart rate or rhythm. Also called *arrhythmia*.

Dysthymia A chronic depressive disorder with symptoms that are less severe than those of major depressive disorder. Also called *persistent depressive disorder* or *dysthymic disorder*.

Dystonia Severe muscle spasms, particularly of the back, neck, tongue, and face.

Dysuria Difficult or painful urination.

Early deceleration During birth, a condition that occurs when the fetal head is compressed and cerebral blood flow decreases, causing central vagal stimulation. Usually associated with the onset of uterine contractions.

Early (primary) postpartum hemorrhage Hemorrhage that occurs in the first 24 hours after childbirth.

Eating disorder A set of maladaptive responses to stress or anxiety characterized by obsessions with food and weight, often to the extent

that daily functioning is impaired and physical and psychologic health are threatened.

Echolalia The compulsive parroting of a word or phrase just spoken by another.

Echopraxia The compulsive imitation of the movements of another.

Eclampsia A major complication of pregnancy characterized by hypertension, albuminuria, oliguria, tonic and clonic convulsions, and coma.

Ecologic theory A theory of development that emphasizes the presence of mutual interactions between the individual and all of life's settings.

Ecomap Visual representation of how the family unit interacts with the external community environment, including schools, religious institutions, occupational duties, and recreational pursuits.

Ectopic beats Impulses originating outside normal conduction pathways of the heart that interrupt the normal conduction sequence and may not initiate a normal muscle contraction.

Edema Swelling caused by excess fluid trapped in body tissue.

Effacement The drawing up of the internal os and the cervical canal into the uterine side walls.

Effectiveness In healthcare, effectiveness is providing services based on scientific knowledge to all who could benefit and refraining from providing services to those not likely to benefit.

Efficiency In healthcare, efficiency is avoiding waste of equipment, supplies, ideas, and energy.

Ego defense mechanisms Unconscious psychologic processes developed for the purpose of defending the personality. Also called *defense mechanisms*.

Egocentrism Ability to see things only from one's own point of view.

Ego-syntonic The perception that one's behaviors and beliefs are normal and any difficulties with other people are external to oneself.

E-health Electronic information that can be retrieved and transferred online or through a mobile device to improve a person's health or healthcare.

Ejection fraction The fraction or percentage of the diastolic volume that is ejected from the heart during systole.

Elasticity of the arterial wall An indicator of the health of an artery. A healthy, normal artery feels straight, smooth, soft, and pliable. Older adults often have inelastic arteries that feel twisted (tortuous) and irregular upon palpation.

Elder abuse The intentional physical, emotional, or sexual mistreatment or neglect of an individual 65 years of age or older.

Elderspeak A speech style similar to baby talk that communicates a message of dependence and incompetence to older adults.

Elective surgery Performed when surgical intervention is the preferred treatment for a condition that is not imminently life threatening (but may ultimately threaten life or well-being) or to improve the patient's life.

Electrocardiogram (ECG) A graphic record of the heart's activity.

Electrocardiography A diagnostic test of cardiac function.

Electroconvulsive therapy (ECT) A treatment procedure during which an electric current is passed through the brain. It is useful to patients with severe depression, acute mania, some psychotic conditions, and those who are acutely suicidal.

Electroencephalogram (EEG) Measures and records the brain's electrical activity.

Electrolyte A charged ion capable of conducting electricity.

Electromyogram A diagnostic technique that measures the electrical activity of the muscles at rest and during contraction.

Electronic communication Transmitting information through email, social networking, text messaging, and other electronic means.

Electronic fetal monitoring (EFM) The measurement and tracing of the fetal heart rate (FHR), which allows many characteristics of the FHR to be visually assessed.

Electronic health record (EHR) A health record system that is designed so that multiple clinicians from multiple disciplines (e.g., family practice, nursing, pharmacy, specialists) can all have simultaneous access to the patient's health information.

Electronic medical record (EMR) A system focused on diagnosis and treatment. EMRs track information over time (weight, blood pressure, cholesterol readings) and identify when patients are due for routine preventive health maintenance such as vaccines and mammograms.

Elimination The secretion and excretion of body wastes from the kidneys and intestines.

Embolus A particle or aggregate of blood, fat, or pathogens or a bubble of air that obstructs a blood vessel.

Embryo The early stage of development of the young of any organism. In humans the embryonic period is from about 2 to 8 weeks' gestation and is characterized by cellular differentiation and predominantly hyperplastic growth.

Embryonic membranes The amnion and chorion.

Emergency A sudden, often unforeseen event that threatens health or safety.

Emergency preparedness The act of making plans to prevent, respond to, and recover from emergencies.

Emergency response The implementation of emergency preparedness plans.

Emergency surgery Surgery that is performed immediately to preserve function or the life of the patient.

Emesis The act of vomiting; occurs when inspiratory muscles of the thorax (including the diaphragm) and abdomen contract, increasing intrathoracic and intra-abdominal pressures.

Emigration The movement of leukocytes through the blood vessel wall into affected tissue spaces in response to illness or injury.

Emotion-focused coping The regulation of emotional responses to distress when the stressor is perceived to be beyond the individual's control.

Emotional availability The quality of parent-child interactions, including parental sensitivity, structuring, and degree of intrusiveness and hostility.

Emotions Feeling responses to a wide variety of emotional stimuli.

Emphysema A progressive pulmonary disease characterized by destruction of the walls of the alveoli, with resulting enlargement of abnormal air spaces.

Empirical knowing The twofold understanding of facts and observations relevant to nursing, and of the analyses and theories that attempt to explain them. Also called the *science of nursing*.

Empyema Accumulation of purulent (infected) exudate in a space, for example, the pleural cavity or the gallbladder.

Enabling behavior Any action by an individual that consciously or unconsciously facilitates substance dependence.

Enamel A hard substance that encapsulates the crown, the uppermost part of the tooth.

Encapsulated Enclosed.

Encoding The selection of specific signs or symbols to transmit a message, such as which language and words to use, how to arrange the words, and what tone of voice and gestures to use.

Encopresis Abnormal elimination pattern characterized by recurrent soiling or passage of stool at inappropriate times.

Enculturation The process by which children learn culture from adults. Also called *cultural transmission*.

End-of-dose medication failure Pain experienced at the end of one dose of medication before the next dose is scheduled.

G-18 Glossary

End of life The final weeks of life when death is imminent.

End-of-life care The nursing care provided to a patient who is dying or who is near death.

End-stage renal disease (ESRD) The final stage of chronic kidney disease, when the kidneys are unable to excrete metabolic wastes and regulate fluid and electrolyte balance adequately.

Endocardial cushion defect A combination of defects in the atrial and ventricular septa and portions of the tricuspid and mitral valves. A complete AV canal defect allows blood to travel freely among all four chambers of the heart. Also called *atrioventricular (AV) canal defect*.

Endocardial cushions Fetal growth centers for mitral and tricuspid valves and AV septum.

Endogenous Developing from within.

Endogenous insulin Insulin that is produced by an individual's own body.

Endogenous pyrogens Interleukins, interferons, and tumor necrosis factor released by macrophages in response to an infection.

Endometriosis A condition that occurs when endometrial tissue implants on organs outside the uterus, causing pain, fibrosis, and adhesions.

Endometrium The innermost mucosal layer of the uterus.

Endotoxins Found in the cell wall of gram-negative bacteria, endotoxins are released only when the cell is disrupted. They act as activators of many human regulatory systems, producing fever, inflammation, and potentially clotting, bleeding, or hypotension when released in large quantities.

Engagement The passing of the fetus into the pelvic inlet in preparation for birth.

Engrossment The characteristic sense of absorption, preoccupation, and interest in an infant demonstrated by fathers during early contact.

Enophthalmos Sunken appearance of the eyes.

Enteral nutrition Tube feeding used to meet calorie and protein requirements in patients who are unable to consume enough food on their own.

Entropion Inversion of the eyelid.

Enuresis Involuntary passing of urine in children after bladder control is achieved.

Environmental health hazards Factors that impede individual and community health and include natural or human-made substances, states, or events which affect the natural environment, produce negative effects on the human ecosphere, and adversely affect health.

Environmental quality One of the 12 leading health indicators identified by *Healthy People 2020*, environmental quality refers to the ability of the environment to promote and sustain individual and community health.

Enzymes Chemicals that induce a chemical reaction in order to assist in the breakdown of nutrients.

Eosinophil A type of leukocyte found in large numbers in the respiratory and gastrointestinal tracts. Eosinophils are thought to be responsible for protecting the body from parasitic worms. They also play a role in the hypersensitivity response by inactivating some of the inflammatory chemicals released during the inflammatory response.

Epidemic Widespread outbreak of infectious disease with many infected people.

Epidermis The surface or outermost part of the skin consisting of four to five layers of epithelial cells.

Epigenetic External influences or effects on gene expression.

Epilepsy A chronic disorder characterized by recurrent, unprovoked seizures secondary to a central nervous system disorder.

Epiphyseal plate Cartilage between the epiphysis and diaphysis found in the long bones of children.

Episiotomy A surgical incision of the perineal body to enlarge the outlet.

Epispadias Congenital abnormality in which the meatus is located on the upper side of the glans.

Epstein's pearls Small, glistening, white specks that feel hard to the touch on the hard palate and gum margins.

Erb-Duchenne paralysis Damage affecting the upper arm between the fifth and sixth cervical nerves, causing paralysis. Also called *Erb palsy*.

Erectile disorder Term used to describe **erectile dysfunction** when the cause of the disorder is unrelated to physical causes (for example, it results as a side effect of a substance or medication).

Erectile dysfunction (ED) The inability of a man to attain and maintain an erection sufficient to permit satisfactory sexual intercourse.

Ergonomics The science of fitting workplace conditions and job demands to the capabilities of the working population.

Erik Erikson A German-born psychologist and psychoanalyst who created a theory of development comprising eight stages or age-related tasks faced by an individual throughout the lifespan.

Erythema A reddening of the skin.

Erythema toxicum An eruption of lesions in the area surrounding a hair follicle that are firm, vary in size from 1 to 3 mm, and consist of a white or pale yellow papule or pustule with an erythematous base. Also called *newborn rash* or *flea bite dermatitis*.

Eschar Hard, leathery crust that covers a burn wound and harbors necrotic tissue.

Escharotomy Surgical removal of eschar from the torso or extremity to prevent circumferential constriction.

Essential nutrients The macro- and micronutrients needed for the body's survival.

Essential tremors Tremors that are not associated with another condition and may be genetic in origin.

Estimated date of birth (EDB) The approximated date of childbirth. Also called estimated date of delivery.

Estrogen The primary hormone responsible for female sex characteristics.

Ethical knowing Understanding and applying the ethical codes by which nurses are expected to abide, as well as upholding the various philosophical, cultural, and moral frameworks of the institution and of the patient. Also called the *moral component*.

Ethics The rules or principles that govern right or moral conduct.

Ethnic group Group of individuals who have common racial characteristics and share a cultural heritage.

Etiology A causal relationship between a problem and its related or risk factors.

Eupnea Breathing within the expected respiratory rates.

Eustachian tube Connects the middle ear with the nasopharynx to help equalize the pressure in the middle ear with the atmospheric pressure.

Eustress Good stress that is associated with accomplishment and victory.

Euthanasia From the Greek for *painless, easy, gentle, or good death*, now commonly used to signify a killing prompted by a humanitarian motive.

Euthymia Stable or normal mood.

Euthyroid A normal thyroid state.

Evaluation Reassessment of a patient following nursing or medical intervention or therapy.

Evaluation statement A written comment on the care plan or in the nurse's notes about progress following an evaluation. An evaluation statement must contain the date and time evaluation was done; a conclusion statement determining goal met, partially met, or not met; and a supporting statement giving the results of how the patient did or did not achieve the goal.

Evaporation The process of converting water to a vapor.

Evidence Clinical knowledge, expert opinion, or information resulting from research.

Evidence-based nursing An integration of the best evidence available, nursing expertise, and the values and preferences of the individuals, families, and communities who are served.

Evidence-based practice The application of research in areas that are of interest to nursing and in the actual practice of nursing.

Evisceration Protrusion of internal viscera through a surgical wound.

Exacerbation A reappearance of symptoms of a chronic illness. Also called a *flare*.

Excess More than is needed in order for the body to survive and remain productive.

Excitement phase This second phase of the sexual response cycle is marked by an increase in blood flow to various body parts, resulting in erection of the penis and clitoris and swelling of the labia, testes, and breasts.

Excoriation Area of loss of the superficial layers of the skin. Also called *denuded area*.

Executive function The mental skills involved in planning and executing complex tasks.

Exercise Physical activity that is planned, structured, and involves repetitive body movements; the goal is to improve or maintain one or more components of physical fitness.

Exercise addiction Excessive pattern of exercising regardless of physical injury, personal inconvenience, or disruption to other areas of life, including marital strain, interference with work, and lack of time for other activities.

Exercise intolerance Decreased ability to participate in activities using large skeletal muscles because of fatigue or dyspnea.

Exogenous Developing from outside sources.

Exogenous insulin Insulin from a source outside the body.

Exophthalmos Protruding eyes.

Exotoxins Soluble proteins that microorganisms secrete into surrounding tissue. Exotoxins are highly poisonous, causing cell death or dysfunction.

Expectorate To expel or spit out.

Expiration The act of exhaling air in respiration.

Expressed consent An oral or written agreement.

Expressive jargon Using unintelligible words with normal speech intonations as if truly communicating in words.

Expressive speech The ability to speak and be understood by others.

Extended family The relatives of nuclear families, such as grandparents, aunts, and uncles.

Extended kin network family A form of extended family in which two nuclear families of primary or unmarried kin live in proximity to each other and share a social support network, goods, and services.

External patients The individuals who seek healthcare as well as their family members and significant others; and other individuals and entities with whom internal patients interact, such as insurance companies, managed care organizations, equipment or material suppliers, social service agencies, and law enforcement officials.

External environmental stressors Triggers outside of an individual that demand change or disrupt homeostasis.

External locus of control The belief that an individual's health is controlled by forces outside of his or her control such as chance or fate.

Extracapsular extraction A surgical treatment for cataracts in which the anterior capsule, nucleus, and cortex of the lens are removed, leaving the posterior capsule intact.

Extracapsular hip fracture A hip fracture involving the trochanteric region between the neck and diaphysis of the femur.

Extracellular fluid (ECF) Fluid found outside the cells. It accounts for about one third of total body fluid and is subdivided into compartments. The two main compartments of ECF are intravascular and interstitial.

Extracorporeal shock wave lithotripsy (ESWL) A noninvasive technique for fragmenting kidney stones using shock waves generated outside the body.

Extrapulmonary tuberculosis Results when tuberculosis spreads through the blood and lymph system to other organs.

Extrapyramidal side effects (EPS) A particularly serious set of adverse reactions to antipsychotic drugs. EPS includes acute dystonia, akathisia, parkinsonism, and tardive dyskinesia.

Extubation The process of withdrawing a breathing tube on completion of anesthesia and the surgical case.

Exudate Material, such as fluid and cells, that has escaped from blood vessels during the inflammatory process and is deposited in tissue or on tissue surfaces.

Exudative macular degeneration A form of macular degeneration characterized by the formation of new, weak blood vessels in the potential space between the choroid and the retina. Also referred to as the wet form of macular degeneration.

Eye movement desensitization and reprocessing (EMDR) A form of psychotherapy that contains elements of a number of types of therapy, including cognitive-behavioral therapy and body-centered therapy.

Failure to thrive (FTT) 1. Inability to meet or maintain developmental milestones related to physical growth due to undernutrition. 2. A syndrome in which an infant falls below the fifth percentile for weight and height on a standard growth chart or is falling in percentiles on a growth chart.

Faith To believe in or be committed to something or someone.

Fallopian tubes Tubes that extend from the lateral angle of the uterus and terminate near the ovary. Also called *oviducts* and *uterine tubes*.

False imprisonment The unjustifiable detention of an individual without legal warrant to confine the person.

False pelvis The portion of the pelvis above the linea terminalis that supports the enlarged pregnant uterus.

Familial AD (FAD) One of the two basic types of Alzheimer disease, it has a strong inherited component and usually manifests before the age of 65. Also called *early-onset Alzheimer disease*.

Family Individuals who are joined together by marriage, blood, adoption, or residence in the same household.

Family burden The overall level of distress experienced by a family as a result of a family member's illness.

Family-centered care A model of healthcare service that is provided in partnership with the patient and family.

Family-centered nursing Nursing that considers the health of the family as a unit in addition to the health of individual family members.

Family cohesion The emotional bonding between family members.

Family communication Includes listening, speaking, self-disclosure, and tracking abilities of the family as a group.

Family coping mechanisms The behaviors families use to deal with stress or changes imposed from either within or without the family.

Family development The dynamics or changes a family experiences over time, including changes in relationships, communication patterns, roles, and interactions.

Family flexibility The amount of change in a family's leadership, role relationships, relationship rules, and ability to respond to stress.

Family recovery Family response to a member's mental illness.

Family support Support from family members as they care for other family members; for example, one sister relieves another to care for their aging mother over the weekend.

Family therapy A form of therapy in which the family system is treated as a unit and the focus is on family dynamics.

Fascial excision Excising a wound to the level of fascia. Also called *fasciectomy*.

Fasciculation An irregular movement or a twitch.

Fasciectomy Excising a wound to the level of fascia. Also called *fascial excision*.

Fat embolism syndrome (FES) Occurs when fat globules lodge in the pulmonary vascular bed or peripheral circulation.

Fatigue A condition characterized by a lack of energy and motivation that may or may not be accompanied by drowsiness.

Fear A sense of apprehension triggered by a perceived threat to safety or well-being, including a painful stimuli or dangerous event.

Febrile Having a fever.

Febrile seizures Generalized seizures that usually occur in children as the result of rapid temperature rise above 39°C (102°F), usually in association with an acute illness. No evidence of intracranial infection or other defined cause is found in relation.

Fecal impaction A mass or collection of hardened feces in the folds of the rectum.

Fecal incontinence The loss of voluntary ability to control fecal and gaseous discharges through the anal sphincter. Also called *bowel incontinence*.

Fecolith A hard mass of feces.

Feces Body wastes and undigested food eliminated from the bowel. Also called *stool*.

Feedback 1. The mechanisms by which some of the output of a system is returned to the system as input. 2. The response a receiver of a message gives to the message's sender.

Female orgasmic disorder The persistent delay or absence of orgasm following a phase of normal sexual excitement.

Female reproductive cycle (FRC) The monthly rhythmic changes in sexually mature women; composed of the ovarian cycle, during which ovulation occurs, and the uterine cycle, during which menstruation occurs.

Female sexual interest/arousal disorder Persistent decreased or absent sexual thoughts, interest in sexual activity, mental or physical feelings of arousal, and/or pleasurable sensation during sexual activity.

Fertility awareness-based methods Contraception based on an understanding of the changes that occur throughout a woman's ovulatory cycle. Also called *natural family planning*.

Fertilization The process by which a sperm fuses with an ovum to form a new diploid cell, or zygote.

Festination Rapid, small steps, as if an individual is trying to run.

Fetal alcohol spectrum disorder See Fetal alcohol syndrome (FAS).

Fetal alcohol syndrome (FAS) A developmental disorder that occurs when a developing fetus is exposed to ethyl alcohol. Fetal alcohol syndrome is associated with physical, intellectual, behavioral, and/or learning disabilities. Also called *fetal alcohol spectrum disorder*.

Fetal attitude The flexion or extension of the fetal body and extremities.

Fetal bradycardia A fetal heart rate of less than 110 bpm during a 10-minute period or longer.

Fetal demise Death of a fetus that occurs after 20 weeks' gestation. Also called a *stillbirth* or *intrauterine fetal death (IUFD)*.

Fetal heart rate (FHR) The number of times the fetal heart beats per minute; normal range is 120–160.

Fetal lie The relationship of the cephalocaudal axis, or spinal column, of the fetus to the cephalocaudal axis, or spinal column, of the woman. The fetus may be in a longitudinal or transverse lie.

Fetal movement record A noninvasive technique that enables the pregnant woman to monitor and record movements easily and without expense.

Fetal position The relationship of the landmark on the presenting fetal part to the front, sides, or back of the maternal pelvis.

Fetal presentation The body part of the fetus entering the pelvis in a single or multiple pregnancy.

Fetal tachycardia A fetal heart rate of 161 bpm or more during a 10-minute period of continuous monitoring.

Fetoscope An adaptation of a stethoscope that facilitates auscultation of the fetal heart rate.

Fetoscopy A technique for directly observing the fetus and obtaining a sample of fetal blood or skin.

Fetus The child in utero from about the seventh to ninth week of gestation until birth.

Fever A protective immune response to foreign antigens within the body that increases the cellular metabolic rate, thus increasing the body's temperature.

Fever of unknown origin A temperature above 100.9°F (38.3°C) that occurs on several occasions within a short time span, lasts for more than 3 weeks, and does not have a definitive cause after 1 week of clinical investigation.

Fever phobia Fear felt by caregivers about the harmful effects of a fever on a child, such as seizure, brain damage, and death.

Fever spike A temperature that rises to fever level rapidly, following a normal temperature, and then returns to normal within a few hours.

Fiber A polysaccharide that contributes to disease prevention, especially in the gastrointestinal tract and the cardiovascular system.

Fibrin Connective tissue.

Fibrin degradation products Potent anticoagulants.

Fibromyalgia A chronic disorder characterized by widespread musculoskeletal pain, fatigue, and multiple tender points.

Fidelity A moral principle that obligates an individual to be faithful to agreements and responsibilities one has undertaken.

Filtration A process whereby fluid and solutes move together across a membrane from a compartment with higher pressure to a compartment with lower pressure.

Filtration pressure The pressure in the compartment that results in the movement of the fluid and substances dissolved in fluid out of the compartment.

Fimbria A funnel-like enlargement of the fallopian tube with many fingerlike projections (fimbriae) reaching out to the ovary.

First heart sound (S₁) The heart sound produced by the closure of the AV valve; characterized by the syllable "lub."

Five P's neurovascular assessment An assessment checklist for pain, pulse, pallor, paralysis/paresis, and paresthesia.

Fixation The immobilization or inability of an individual to proceed to the next developmental stage because of anxiety.

Flaccidity Absence of muscle tone. Also called *hypotonia*.

Flashbacks The recurrence of images, sounds, smells, or feelings from a traumatic event; often triggered by daily events, such as a car backfiring on the street or the smell of a perpetrator's cologne.

Flat affect Minimal facial expression and movement, sometimes monotone speech patterns.

Flatness An extremely dull sound produced by very dense tissue, such as muscle or bone.

Flatulence The presence of excessive amounts of gas in the stomach or intestines.

Flatus Gas or air normally present in the stomach or intestines.

Flight of ideas Rapidly changing, fragmentary thoughts.

Flow sheet A specific assessment criteria in a particular format, such as human needs or functional health patterns.

Fluid resuscitation The administration of intravenous (IV) fluids to restore circulating blood volume during an acute period of increasing capillary permeability.

Fluid volume deficit (FVD) Substantial loss of both water and electrolytes in similar proportions from the extracellular fluid. Also called *hypovolemia*.

Fluid volume excess (FVE) Excessive fluid retained by the body. The retention of both water and sodium in similar proportions to normal extracellular fluid (ECF). Also called *hypervolemia*.

Fluoroscope A scope used to project visual examination images on a fluorescent screen.

Focal seizures Seizures that are caused by abnormal electrical activity in one hemisphere or in a specific area of the cerebral cortex, most often the temporal, frontal, or parietal lobes. The seizure may spread regionally, and the symptoms are related to the region of the cortex that is affected. Also known as *partial seizures*.

Focus charting Date and time, focus, and progress notes are recorded for a specific condition, nursing diagnosis, and behavior to make the patient and the patient's concerns and strengths the focus of care.

Folic acid A vitamin that is required for normal growth, reproduction, and lactation and that prevents the macrocytic, megaloblastic anemia of pregnancy.

Follicle-stimulating hormone (FSH) Hormone produced by the anterior pituitary during the first half of the menstrual cycle, stimulating development of the graafian follicle.

Fontanels The intersections of membranous spaces between the cranial bones of a fetus.

Food choice An individual's decision of what and how much to eat of a specific food. This decision can be influenced by a number of conscious and unconscious factors such as taste, preparation, smell, habits, convenience, availability, and cost.

Food insecurity Results when one or more members of a household must reduce their eating patterns due to a lack of money or lack of resources to access appropriate amounts and varieties of food.

Food security Results when all members of a household have sufficient resources to access appropriate amounts and varieties of food.

Foramen ovale An opening between the atria of the fetal heart.

Foraminotomy An enlargement of the opening between the disc and the facet joint to remove bony overgrowth.

Forced expiratory volume in 1 second (FEV₁) The amount of air that can be exhaled in 1 second as measured by a spirometer.

Forceps-assisted birth The use of forceps to assist the birth of a fetus by providing traction or by providing the means to rotate the fetal head to an occiput-anterior position. Also called an *instrumental delivery*, *operative delivery*, or *operative vaginal delivery*.

Forceps marks Reddened areas over the cheeks and jaws on an infant caused by a difficult forceps birth.

Foreground question Questions that are narrow in focus about a specific clinical issue.

Foreseeability The ability to foresee events that reasonably may be expected to cause specific results.

Formal group A group with formalized goals, designated management, and only partly voluntary membership.

Formal leader A leader who is selected by an organization and given official authority to make decisions and act.

Formation The process that facilitates the transformation of an individual from a layperson to a professional nurse.

Foster family A family consisting of one or more adults caring for one or more children from other families when the children can no longer live with their birth parents.

Fourth heart sound (S₄) A heart sound produced by atrial contraction and ejection of blood into the ventricle during late diastole. Also called *atrial gallop*.

Fracture A break in the continuity of a bone.

Fragile X syndrome A developmental disorder caused by a single recessive gene abnormality on the X chromosome. Fragile X syndrome is associated most notably with intellectual disability, often accompanied by ADHD and other behavioral problems.

Frank-Starling mechanism An increase in venous return increases ventricular filling and myocardial stretch, which increases the force of contraction.

Free-floating anxiety Excessive worry about everyday events; worry that is hard to control and the focus of which may shift from moment to moment.

Freezing A condition in which an individual feels like his or her feet are stuck to the floor.

Frequency The time between the beginning of one contraction and the beginning of the next contraction.

Friend support Support or assistance from nonfamily members, such as friends or coworkers, for a family during a time of illness or stress.

Frostbite An injury of the skin resulting from freezing.

Frustration An emotion that occurs when an individual is prevented from reaching a desired goal. Intense frustration may trigger violent aggressive tendencies resulting in assault or homicide.

Fulguration A procedure that destroys tissue with electrical current.

Full-thickness burn A burn that involves all layers of the skin, including the epidermis, the dermis, and the epidermal appendages.

Fulminant colitis An acute form of ulcerative colitis that involves the entire colon; manifestations include severe bloody diarrhea, acute abdominal pain, and fever.

Functional assessments Typically a combination of assessments that includes observations of child behavior, responses, and abilities. It is used to assess how a child functions on a daily basis in his or her environment and to determine if the child has any developmental delays or special needs.

Functional method A method of coordinating care that focuses on the jobs to be completed as part of patient care (e.g., bed making and temperature measurement). In this task-oriented approach, personnel with less educational preparation than the professional nurse (e.g., unlicensed assistive personnel) perform aspects of care with less complex requirements.

Functional nursing A task-oriented approach to care delivery used in situations of inadequate staffing or nursing shortages.

Functional strength The body's ability to perform work.

Fundus The rounded, uppermost portion of the uterus.

Fungi A type of microorganism capable of producing infection. Yeasts and molds are common types of fungi.

Galanin A neuropeptide that is released by neurons as they are injured or die. Often associated with Alzheimer disease, although the exact role galanin plays in the disease is unknown.

Gallstone ileus A large gallstone.

Gambling disorder An **addiction** to gambling characterized by gambling despite the risk of losing something of value (e.g., a home) and an inability to stop gambling.

Gamete Female or male germ cell; contains a haploid number of chromosomes.

Gametogenesis The process by which germ cells are produced.

Gastric lavage Irrigation of the stomach with large quantities of normal saline.

Gastric outlet obstruction Obstruction of the pyloric region of the stomach and duodenum that impairs gastric outflow; a potential complication of peptic ulcer disease.

Gastric ulcer A peptic ulcer that occurs in the stomach.

Gastrocolic reflex The increased peristalsis of the colon after food has entered the stomach.

Gastroesophageal reflux disease (GERD) A disease in which stomach contents flow back up into the esophagus.

Gate control theory Melzack and Wall's 1965 theory stating that the perception of pain is controlled by the overall activity of small-diameter (pain) fibers vs. large-diameter (heat, cold, mechanical) fibers.

G-22 Glossary

Gender identity One's self-image as a female or male.

Gender-role behavior The outward expression of an individual's sense of maleness or femaleness as well as the expression of what is perceived as gender-appropriate behavior.

General adaptation syndrome (GAS) A three-stage chain of events in an individual's stress response.

Generalized anxiety disorder (GAD) A condition that occurs when an individual experiences intense tension and worry, even if no external stressors are present.

Generalized seizures The result of diffuse electrical activity that often begins in both hemispheres of the brain simultaneously, then spreads throughout the cortex into the brainstem. As a result, movements and spasms displayed by the patient are bilateral and symmetric.

Generational cohort Individuals born in the same general time span who share key life experiences, including historical events, public heroes, pastimes, and early work experiences.

Genital herpes A sexually transmitted infection caused by the herpes simplex virus.

Genital intercourse Penetration of the vagina by the penis. Also called *coitus*.

Genital warts A sexually transmitted infection caused by the human papillomavirus (HPV).

Genito-pelvic pain/penetration disorder Persistent or recurrent dyspareunia (pain) or fear of pain before or during vaginal penetration.

Genogram Visual representation of gender showing lines of birth descent through the generations.

Genotype The pattern of genes on chromosomes.

Geographic information system (GIS) A system that relies on satellite imaging and global positioning systems to capture, manage, and analyze geographical data.

Geragogy The process of stimulating and helping older adults to learn.

Geriatric failure to thrive (GFTT) A condition in which older patients experience a multidimensional decline in physical functioning that is characterized by weight loss of more than 5% of baseline body weight, decreased appetite, undernutrition, dehydration, depression, and cognitive and immune impairment.

Gestation Period of intrauterine development from conception through birth; pregnancy.

Gestational age assessment tools Methods to determine an infant's age at birth assessing external physical characteristics and neurologic or neuromuscular development.

Gestational diabetes mellitus (GDM) A carbohydrate intolerance of variable severity with onset or first recognition during pregnancy.

Gingiva The gum.

Gingivitis Red, swollen gingiva.

Glaucoma A condition characterized by optic neuropathy with gradual loss of peripheral vision and, usually, increased intraocular pressure of the eye.

Global evaluative dimension of the self The degree to which an individual likes him- or herself overall, as a whole being. Also called *global self-esteem*.

Global self The collective beliefs and images an individual holds about him- or herself.

Global self-esteem See Global evaluative dimension of the self.

Glomerular filtration rate (GFR) The rate at which fluid is filtered through the kidneys.

Glomerulonephritis Inflammation of the glomerular capillary membrane.

Glomerulus Found in the nephrons of the kidneys, a tuft of capillaries surrounded by the Bowman capsule.

Glucagon Produced by alpha cells, glucagon is a hormone that decreases glucose oxidation and promotes an increase in the blood

glucose level by signaling the liver to release glucose from glycogen stores. In addition to stimulating the breakdown of glycogen in the liver, glucagon stimulates the formation of carbohydrates in the liver and the breakdown of lipids in both the liver and adipose tissue.

Gluconeogenesis The formation of glucose from fats and proteins.

Glucosuria The excretion of glucose in the urine.

Glycogenolysis The breakdown of liver glycogen.

Glycosuria The excretion of carbohydrates into the urine.

Goiter An enlarged thyroid gland

Gonadotropin-releasing hormone (GnRH) A hormone secreted by the hypothalamus that stimulates the anterior pituitary to secrete follicle-stimulating hormone and luteinizing hormone.

Gonorrhea A sexually transmitted infection caused by *Neisseria gonorrhoeae*.

Good-faith immunity Law or laws that protect healthcare workers from civil or criminal liabilities when they report suspected child abuse in good faith, even if the subsequent investigation does not make a determination of abuse.

Good Samaritan laws Specific laws designed to protect healthcare workers from potential liability when volunteering their skills outside of an employment contract.

Goodpasture syndrome A rare autoimmune disorder of unknown etiology that is characterized by formation of antibodies to the glomerular basement membrane.

Governance The establishment and maintenance of social, political, and economic arrangements by which professionals control their practice, their self-discipline, their working conditions, and their professional affairs.

Graafian follicle The ovarian cyst containing the ripe ovum, which secretes estrogens.

Grading A standardized method of judging a tumor's aggressiveness based on the level of differentiation and mitotic rate; where the least malignant cells are classified grade 1 and the most aggressive malignant cells are classified grade 4.

Graft-versus-host disease (GVHD) A series of immunologic reactions in response to transplanted cells.

Gram stain A diagnostic test conducted to identify infecting organisms in urine by shape and characteristic.

Granulation tissue Young connective tissue with new capillaries formed in the healing process.

Grasping reflex The closing and grasping of an infant's fingers in response to a finger placed in the palm of the infant's hand.

Graves disease An autoimmune disorder marked by an enlarged thyroid and signs of hyperthyroidism.

Grief The total psychologic, biological, and behavioral response to the emotional experience related to loss.

Group Three or more individuals who have a common purpose, interact with each other, influence each other, and are interdependent.

Group therapy A form of therapy that allows group members to help each other with psychologic, cognitive, behavioral, and spiritual dysfunctions through a process of change, aided by a professional group therapist.

Groupthink A type of decision making characterized by a group's failure to critically examine their own processes and practices or to recognize and respond to change.

Growth Physical change and increase in size.

Guillain-Barré syndrome (GBS) An acute inflammatory demyelinating disorder of the peripheral nervous system characterized by an acute onset of motor paralysis (usually ascending).

Gustatory Of or relating to taste.

Gynecomastia Abnormal enlargement of the breast(s) in men.

H₁ receptors Cellular histamine receptors that are present in the smooth muscle of the vascular system, the bronchial tree, and the digestive tract. Stimulation of these receptors results in itching, pain, edema, bronchoconstriction, and other characteristic symptoms of inflammation and allergy.

H1N1 influenza A form of the influenza virus that consists of avian genes, human genes, and genes from flu viruses typically found in pigs from Asia and Europe. Once mistakenly called *swine flu*, it can be spread through human-to-human transmission.

H₂ receptors Cellular histamine receptors present primarily in the stomach; their stimulation results in the secretion of large amounts of hydrochloric acid.

Habit training Attempts to keep patients dry by having them void at regular intervals.

Habituation The newborn's ability to process and respond to complex stimulations.

Hallucination The perception of seeing, hearing, or feeling something that is not present in reality.

Hallucinogen A type of drug that induces the same types of thoughts, perceptions, and feelings that occur in dreams. Hallucinogens include PCP, 3,4-MDMA, D-lysergic acid diethylamide (LSD), mescaline, dimethyltryptamine (DMT), and psilocin.

Hand restraints A device used to protect confused patients from scratching or injuring their skin, or dislodging intravenous access devices. Also called *mitt restraints*.

Handoff The transfer of information along with authority and responsibility during transitions in care across the continuum.

Handoff communication A verbal or written exchange of information. It encompasses the nursing team and all other members of the healthcare team who care for a patient at any given time.

Hardware The physical component of technology, including computers, keyboards, and display screens.

Harlequin sign A reddening of the skin on one side of an infant's body while the other side remains pale. Also called *clown color change*.

Hashimoto thyroiditis An autoimmune disorder in which antibodies destroy thyroid tissue.

Hassles Day-to-day tension/stressors.

Health A state of complete physical, mental, and social well-being.

Health beliefs Concepts about health that an individual believes are true, regardless of whether or not they are founded in fact.

Health Insurance Portability and Accountability Act (HIPAA) Legislation enacted by Congress to minimize the exclusion of preexisting conditions as a barrier to healthcare insurance, designate special rights for those who lose other health coverage, and eliminate medical underwriting in group plans. The act includes the Privacy Rule, which creates a national standard for the disclosure of private health information.

Health Level Seven (HL7) A framework designed for the exchange, integration, sharing, and retrieval of electronic health information that supports clinical practice and the management, delivery, and evaluation of health services.

Health literacy The ability to read, understand, and act on health information, including such tasks as comprehending prescription labels, interpreting appointment slips, completing health insurance forms, and following instructions for diagnostic tests.

Health maintenance organization (HMO) The most restrictive type of private health insurance plan. HMO participants must select a primary care provider who provides basic medical services and, as the gatekeeper to care, refers the patient to in-network hospitals and specialists when additional care is needed.

Health policy The actions and decisions by government bodies and professional organizations that affect whether or not healthcare organizations and individuals working within the healthcare system can achieve their healthcare goals.

Health promotion A way of thinking and acting in order to increase individuals' overall health and well-being regardless of their health and illness status or age.

Health restoration Care focusing on the ill patient that extends from early detection of disease through helping the patient during the recovery period.

Healthcare advance directive Legal document that allows an individual to plan for healthcare and/or financial affairs in the event of incapacity. Also called *advance directive* or *advance healthcare directive*.

Healthcare-associated infection (HAI) Infections associated with the delivery of healthcare services in a facility such as a hospital or nursing home. Also called a *nosocomial infection*.

Healthcare disparity A difference in a measurement of access to or quality of healthcare services between an individual or group possessing a defined characteristic when other variables have been controlled, such as individual health choices, disease courses, and other variations from the normative measure.

Healthcare proxy An individual selected to speak to physicians and other healthcare providers on behalf of a patient to determine the best course of treatment.

Healthcare surrogate An individual selected to make medical decisions when someone is no longer able to make them for him- or herself.

Heart block A block in the normal electrical conduction of the heart.

Heart failure The inability of the heart to pump adequate blood to meet the metabolic demands of the body.

Heart murmur Harsh, blowing sounds caused by disruption of blood flow into the heart, between the chambers of the heart, or from the heart into the pulmonary or aortic systems.

Heartburn A burning sensation in the chest or throat. Also called *pyrosis*.

Heat balance When the amount of heat produced by the body equals the amount of heat lost.

Heat exhaustion Excessive heat exposure and dehydration that causes paleness, dizziness, nausea, vomiting, fainting, and a moderately increased temperature (38.3°–38.9°C [101°–102°F]).

Heat stroke A serious form of heat exhaustion that can be life threatening, generally caused by exercising in hot weather. Patients will have warm, flushed skin, often do not sweat, and have a temperature of 41°C (106°F) or higher. A patient may be also delirious, unconscious, or having seizures.

Heat transfer The four ways heat moves from one place or object to another place or object.

Heaving Lifting of the chest wall during contraction.

Heberden nodes Bony lumps on the end joint of a digit.

Helper T cells Play a vital role in normal immune system function, recognizing foreign antigens and infected cells and activating antibody-producing B cells. They are the primary cells infected by the human immunodeficiency virus.

HELPP syndrome A cluster of changes, including hemolysis, elevated liver enzymes, and low platelet count, sometimes associated with pre-eclampsia.

Hematochezia Bright blood in the stool.

Hematocrit The proportion of cells and plasma in blood. Also refers to the laboratory test that measures the hematocrit. This test can also be used to detect severe dehydration or overhydration.

Hematogenous spread Describes the spread of infection or disease through the blood.

Hematoma A localized collection of blood underneath the skin that may appear as a bruise.

Hematopoiesis Blood cell formation.

Hematuria The presence of blood in the urine.

Hemianopia The loss of half of the visual field of one or both eyes.

G-24 Glossary

Hemiarthroplasty Hip replacement that involves replacement of the ball, the head, or the femur.

Hemiarthroscopy The surgical replacement of the femoral head with a smooth metal sphere.

Hemiparesis Weakness of the left or right half of the body.

Hemiplegia Paralysis of the left or right half of the body.

Hemispheres The two halves created by the division of the cerebrum by the deep fold.

Hemodialysis A process by which a patient's blood flows through vascular catheters, passes by the dialysate in an external machine, and then returns to the patient.

Hemodynamics The study of forces involved in blood circulation.

Hemoglobin The oxygen-carrying molecule within red blood cells; a laboratory test to measure the amount of hemoglobin.

Hemoglobinopathy A disorder of hemoglobin.

Hemolysis The destruction of red blood cells; releases hemoglobin into the circulation.

Hemolytic anemia A disorder that results from the premature destruction of red blood cells.

Hemoptysis Bloody sputum.

Hemorrhage Rapid or excessive bleeding.

Hemosiderosis The storage of excessive iron in tissues and organs.

Hemostasis The cessation of bleeding.

Hemotympanum Bleeding into or behind the tympanic membrane.

Hepatitis The inflammation of the liver triggered by a virus, alcohol, medications, toxins, autoimmune disorder, or other pathogens.

Here-and-now concept A concept used in group therapy that recognizes that only in the present moment of a group's experience can change be made.

Hernia A protrusion in the intestine through the inguinal wall or canal.

Herniated intervertebral disc A rupture of the cartilage surrounding the intervertebral disc with protrusion of the nucleus pulposus. Also called a *ruptured disc*, *slipped disc*, or *herniated nucleus pulposus*.

Heroin An illicit, central nervous system depressant narcotic that alters perception and produces euphoria.

Heterograft Skin used for transplantation that was obtained from an animal, usually a pig. Also called a *xenograft*.

Heterosexism The view that heterosexuality is the only correct sexual orientation.

Heterosexual An individual who is attracted to members of the opposite sex.

Highly active antiretroviral therapy (HAART) Effective treatment of AIDS that combines at least three medications to inhibit HIV replication.

Hip fracture A fracture of the femur at the head, neck, or trochanteric regions.

Hippocampus A small, curved body in the brain. Part of the limbic system, it plays a major role in memory formation.

Hirsutism An increased growth of coarse hair on the face and trunk.

Histamine A key chemical mediator of inflammation.

Histrionic personality disorder (HPD) One of several personality disorders defined in the DSM-5, it is characterized by a lifelong tendency for dramatic, egocentric, attention-seeking response patterns.

Hoarding compulsion An excessive collection and accumulation of objects, extreme cluttering of the living environment, accompanied by a lack of regard for the embarrassment of family member or others whose living is impacted.

Holistic health A clinical mindset that considers more than the physiologic health status of an individual.

Holosystolic Term used to describe the sounds heard during the entire phase of systole.

Holy day A day set aside for special religious observance.

Homan sign Pain in the calf when the foot is dorsiflexed.

Homeostasis The body's ability to maintain a state of physiologic balance in the presence of constantly changing conditions.

Homicide The killing of one individual by another; for legal purposes, this act is further specified by whether the act was intentional or due to negligence.

Homocysteine An amino acid that is a homologue of cysteine.

Homograft Grafts between members of the same species who have different genotypes and HLA antigens. Usually human skin that has been harvested from cadavers. Also called an *allograft*.

Homologous chromosomes The two paired chromosomes that are inherited, one from each parent.

Homophobia The fear, hatred, or mistrust of gays and lesbians often expressed in overt displays of discrimination.

Homosexual An individual who is attracted to members of the same sex.

Hope To expect or desire with confidence.

Horizontal violence (HV) Aggressive acts committed against a nurse by one or more nursing colleagues.

Hormone replacement therapy (HRT) Administration of hormones, usually estrogen and a progestin, to alleviate the symptoms of menopause.

Hormones Chemical messengers secreted by various glands that exert controlling effects on the cells of the body.

Hospice An organization that provides end-of-life care for patients either in their homes or in a hospital setting.

Hospice care The support and care for persons in the last phase of an incurable disease so that they may live as fully and comfortably as possible until their death.

Hot zone When a disaster occurs, the hot zone is the most dangerous zone because it is located immediately adjacent to the site of the disaster. All responders who enter the area must be protected by personal protective equipment.

Human chorionic gonadotropin (HCG) A hormone produced by the chorionic villi that is found in the urine of pregnant women. Also called *prolan*.

Human dignity The inherent worth and uniqueness of individuals and populations.

Human immunodeficiency virus (HIV) A primary immunodeficiency disorder that is spread primarily through sexual contact with an infected person. HIV is the virus that causes acquired immunodeficiency syndrome (AIDS).

Human leukocyte antigen (HLA) The major histocompatibility complex gene.

Humanistic learning theory A learning theory that focuses on the unique cognitive and affective qualities of a learner.

Humoral immune response Hyperreactive response of B cells characteristic of systemic lupus erythematosus (SLE).

Hunger The feeling that makes individuals think of food and encourages them to satisfy this feeling by eating.

Hyaluronic acid (HA) A lubricating substance in cartilage and joint synovial fluid.

Hydrocephalus A condition characterized by enlargement of the head caused by inadequate drainage of cerebrospinal fluid.

Hydronephrosis An accumulation of urine in the renal pelvis as a result of obstructed outflow.

Hydrostatic pressure The pressure a fluid exerts within a closed system on the walls of its container. The hydrostatic pressure of blood is the force blood exerts against the vascular walls (e.g., the artery walls). The principle involved in hydrostatic pressure is that fluids move from an area of greater pressure to an area of lesser pressure.

Hydroureter Distention of the ureter with urine.

Hyperalgesia Increased response to a pain stimulus because of peripheral sensitization.

Hypercalcemia Elevated blood levels of calcium.

Hypercapnia A condition marked by a PaCO_2 level above 45 mmHg. Also known as **hypercarbia**.

Hypercarbia See Hypercapnia.

Hyperchloremia Elevated chloride levels in the blood.

Hypercyanotic episode A potentially life-threatening episode of hypoxia. Also called a *tet episode*.

Hyperemia Increased blood flow to an area.

Hyperextension Forcible backward bending.

Hyperflexion Forcible forward bending.

Hyperglycemia Elevated glucose levels.

Hyperkalemia Elevated potassium levels in the blood.

Hypermagnesemia Elevated magnesium levels in the blood.

Hypernatremia Elevated sodium levels in the blood.

Hyperopia Farsightedness.

Hyperosmolar hyperglycemic state (HHS) A disorder characterized by a plasma osmolality of 340 mOsm/L or greater, greatly elevated blood glucose levels, and altered levels of consciousness. It occurs in individuals who have type 2 diabetes mellitus.

Hyperphosphatemia Increased blood levels of phosphate.

Hyperplasia An increase in the number or density of normal cells.

Hyperresonance An abnormal, booming sound that can be heard over an emphysematous lung.

Hyperresponsiveness An exaggerated response, as with bronchoconstriction in asthma.

Hypersensitivity An overreaction of the immune system to an antigen or antigens.

Hypersomnia The inability to stay awake during the day, despite obtaining sufficient sleep at night.

Hypertension Excess pressure in the arterial portion of the circulatory system, specifically a systolic blood pressure of 140 mmHg or higher or a diastolic blood pressure of 90 mmHg or higher.

Hypertensive crisis A systolic blood pressure greater than 180 mmHg and diastolic blood pressure higher than 120 mmHg. Also called *malignant hypertension*.

Hypertensive encephalopathy A syndrome characterized by extremely high blood pressure, altered level of consciousness, increased intracranial pressure, papilledema, and seizures.

Hyperthermia A condition that occurs when a body produces more heat than is lost.

Hyperthermia blanket An electronically controlled blanket that provides a specified temperature

Hyperthermic A body temperature above 37.8°C (100°F).

Hyperthyroidism A disorder caused by excessive delivery of thyroid hormone to the peripheral tissues. Also called *thyrotoxicosis*.

Hypertonic Refers to solutions that have a higher osmolality than body fluids; 3% sodium chloride is a hypertonic solution.

Hypertonic dehydration Occurs when sodium loss is proportionately less than water loss. Also called *hypernatremic dehydration*.

Hypertrophic cardiomyopathy A disorder characterized by decreased compliance of the left ventricle and hypertrophy of the ventricular muscle mass.

Hypertrophic scar An overgrowth of dermal tissue that remains within the boundaries of the wound.

Hypertrophy An enlargement of glandular cells or muscles.

Hyperventilation Unusually fast respirations, or overbreathing causing an imbalance of oxygen and carbon dioxide.

Hypervolemia The excessive retention of both water and sodium in similar proportions to normal extracellular fluid (ECF). Also called *fluid volume excess*.

Hyphema Bleeding into the anterior chamber of the eye.

Hypoactive sexual desire disorder A deficiency in or absence of sexual fantasies and persistently low interest or a total lack of interest in sexual activity.

Hypocalcemia Decreased blood levels of calcium.

Hypocapnia A condition that results when PaCO_2 falls below 35 mmHg. Also called **hypocarbica**.

Hypocarbica See Hypocapnia.

Hypochloremia Decreased blood levels of chloride.

Hypodermis The layer of loose connective tissue and fat cells that lies below the dermis. Also called *subcutaneous tissue*.

Hypodermoclysis Fluid administered subcutaneously.

Hypoglycemia Diminished glucose levels.

Hypokalemia Decreased blood levels of potassium.

Hypomagnesemia Decreased blood levels of magnesium.

Hypomania A less extreme form of mania that is not severe enough to markedly impair functioning or require hospitalization.

Hyponatremia Decreased blood levels of sodium.

Hypoperfusion Decreased blood flow.

Hypophonia A lowered voice volume.

Hypophosphatemia Decreased blood levels of phosphate.

Hypoplastic left heart syndrome (HLHS) One of the most severe congenital heart defects, characterized by absence or stenosis of mitral and aortic valves, an abnormally small left ventricle, a small aorta, and aortic or mitral stenosis or atresia.

Hypotension A below-normal blood pressure reading between 85 and 110 mmHg.

Hypothalamic-pituitary axis In the brain, the HPA is responsible for the regulation of endocrine glands, and consequently, hormones.

Hypothermia A condition that occurs when a body loses more heat than it produces.

Hypothermic A body temperature below 36°C (97°F).

Hypothyroidism A disorder resulting when the thyroid gland produces an insufficient amount of thyroid hormone.

Hypotonic Refers to solutions that have a lower osmolality than body fluids, such as one half normal saline.

Hypotonic dehydration Occurs when fluid loss is characterized by a proportionately greater loss of sodium than water. Also called *hyponatremic dehydration*.

Hypoventilation An abnormally slow respiratory rate leads to inadequate oxygen delivery to the lungs as well as an increase in retention of carbon dioxide.

Hypovolemia Loss of both water and electrolytes in similar proportions from extracellular fluid. Also called *fluid volume deficit*.

Hypovolemic shock Shock caused by a decrease in intravascular volume of 15% or more.

Hypoxemia Decreased oxygen levels in the blood that result when PaO_2 falls below 80 mmHg.

Hypoxia Decreased delivery of oxygen to the tissues.

Iatrogenic Refers to a condition induced by the effects of treatment.

Iatrogenic infection A type of infection that results directly from diagnostic or therapeutic procedures.

Ideal body image A mental representation of what an individual believes his or her body should look like.

Ideal self How the individual thinks he or she should be or would prefer to be.

Idiopathic pain A type of pain that occurs unpredictably and is not associated with any known cause, making it difficult to treat.

Ileostomy A surgical opening made in the ileum of the small intestine.

Ileus A condition that causes a temporary cessation of the passage of material through the intestines, usually lasting 24–48 hours.

Illness A state in which an individual's physical, emotional, intellectual, social, developmental, or spiritual functioning is diminished.

Illness behavior A coping mechanism that includes the ways in which an individual describes, monitors, and interprets symptoms, and the individual's ability to take remedial action and use the healthcare system.

Illness prevention Healthcare focusing on maintaining optimal health by preventing disease through programs on immunizations, prenatal and infant care, and prevention of sexually transmitted infections.

Illusion A distorted perception of actual sensory stimuli.

Imagery A relaxation technique in which the patient focuses on pleasant images such as a beach or a garden to replace negative images such as pain and darkness. Also called *guided imagery*.

Imitation The process by which individuals copy or reproduce what they have observed.

Immobility A reduction in the amount and control of one's movement.

Immunity The body's natural or induced response to infection and the conditions associated with its response.

Immunization Introduces an antigen into the body, allowing immunity against a disease to develop naturally.

Immunocompetent Term used to describe patients who have an immune system that identifies antigens and effectively destroys or removes them.

Immunodeficiency A condition that develops when the immune system is incompetent or unable to respond effectively.

Immunoglobulin (Ig) A protein that functions as an antibody.

Immunosuppression Inability of the immune system to respond to an antigen. Occurs in response to disease or medications; may be intentional to prevent rejection of transplants or a side effect of some medications.

Implied consent Nonverbal consent indicated by a patient's cooperative actions.

Impotence Inability to achieve or maintain an erection.

Impulse conduction The transmission of an impulse along the nerve pathways to the spinal cord and directly to the brain.

Impulsiveness Acting without considering the consequences of one's behavior. Also called *impulsivity*.

In vitro fertilization A process in which a woman's eggs are collected from her ovaries, fertilized in the laboratory, and then placed into her uterus after normal embryo development has begun.

Incentive spirometry A breathing exercise using an incentive spirometer that helps patients breathe deeply to expand the lungs. This process can help patients clear mucus secretions and increase the amount of oxygen delivered to the bronchi and alveoli.

Incident pain A type of breakthrough pain that is predictable because it is precipitated by an event or activity such as coughing or changing position.

Incident report An agency record of an accident or incident occurring within the agency. This record is designed to collect adequate information to assist personnel in preventing future incidents or occurrences. Also called *variance reports* or *unusual occurrence reports*.

Incomplete spinal cord injury An injury that involves only a partial loss of sensory and motor function below the level of the injury.

Increased intracranial pressure (IICP) Sustained, elevated pressure (15 mmHg or higher in adults) in the cranial cavity.

Indemnity plan A type of health insurance program that allows the insured to self-select healthcare providers and has no predefined network.

Independent intervention The activities that nurses are licensed to do within their scope of practice; in other words, areas of healthcare that are unique to nursing and separate and distinct from medical management.

Indicator A statistic that reflects the organization's performance in a specific area.

Inductive reasoning A "bottom-up" method of logical thinking that starts with putting significant cues together in order to reach a conclusion. It is a method of logical thinking that is used to determine if decisions are reasonable.

Infantile glaucoma **Congenital glaucoma** diagnosed within the first year of life.

Infection An invasion of the body tissue by microorganisms with the potential to cause illness or disease.

Infectious disease Any communicable disease that is caused by microorganisms that are commonly transmitted from one person to another or from an animal to an individual.

Infertility A lack of conception despite unprotected sexual intercourse for at least 12 months.

Inflammation An adaptive response to what the body sees as harmful, such as an allergen, illness, or injury. Inflammation typically is characterized by pain, heat, redness, and swelling. Also called *inflammatory response*.

Inflammatory bowel disease (IBD) Chronic inflammation of the bowel common to a group of conditions that includes Crohn disease and ulcerative colitis.

Influenza A highly contagious viral respiratory disease characterized by coryza (inflammation of the mucous membranes lining the nose usually associated with nasal discharge), fever, cough, and systemic symptoms such as headache and malaise (vague feeling of physical discomfort).

Informal groups A type of group that functions with much less structure than a formal or semiformal group. Characteristics of informal groups include easily recognized, basic objectives; rotational leadership; and no set of written rules or regulations.

Informal leader A leader who is not officially appointed to direct the activities of others but, because of seniority, age, or special abilities, is recognized by the group as a leader and plays an important role in influencing colleagues, coworkers, or other group members to achieve the group's goals.

Informed consent 1. A patient's legal and ethical rights to be informed of and give permission for any healthcare procedure or treatment. 2. A study volunteer's legal right to be informed with full disclosure of the study's purpose, required procedures, length of the study, expectations, risks, and possible benefits before consenting to participate. Informed consent also includes the right to withdraw from the study at any time.

Infundibulopelvic ligament A ligament that suspends and supports the ovaries.

Inhalant A substance inhaled to produce euphoria. Categorized into three types: anesthetics, volatile nitrites, and organic solvents.

Injury An act or event that causes damage, harm, or loss to a body's functioning.

Input Information, material, or energy that enters a system.

Inquiry A search for knowledge or facts in order to gain clarification and find solutions to problems.

Insensible fluid loss Fluid loss that is not perceptible to the individual and cannot be measured.

Insomnia The inability to fall asleep or remain asleep.

Inspection A visual, auditory, and olfactory examination or assessment of a patient to note health condition.

Inspiration The act of inhaling air in respiration.

Instrumental aggression Aggression executed in the absence of emotional arousal.

Insubordination Defiance of authority, such as the refusal to complete a task as assigned.

Insulin A hormone that facilitates the uptake and use of glucose by cells and prevents an excessive breakdown of glycogen in the liver and muscle. In doing so, insulin acts to decrease blood glucose levels.

Insulin reaction Low blood glucose levels, or hypoglycemia. Also called *insulin shock*.

Integrative health The process of incorporating **complementary health approaches** into mainstream Western healthcare.

Integrity Adherence to a strict moral or ethical code.

Integumentary system The body's system that includes skin, hair, and nails and the sebaceous, sweat, and mammary glands.

Intellect The ability to learn and understand knowledge; the capacity for thinking and reasoning intelligently.

Intellectual disability Significant limitations in intellectual functioning and adaptive behavior prior to the age of 18. Previously called *mental retardation*.

Intellectual functioning General intelligence or mental capacity, including an individual's abilities to learn, use logic, and solve problems.

Intensity 1. The amplitude of a sound produced. 2. The strength of the contraction during acme, the peak of a uterine contraction during the birth process.

Interdisciplinary assessment An assessment that involves more than one discipline such as nursing and physical therapy. Also called *interprofessional assessment*.

Interdisciplinary team A team that seeks to achieve a common goal, though the team members are professionals with varied backgrounds. Also called *interprofessional team*.

Intergroup conflict Conflict that occurs between teams that are in competition or opposition to one another.

Intermittent claudication A cramping or aching pain in the calves of the legs, the thighs, and the buttocks that occurs with a predictable level of activity.

Intermittent fever Occurs when body temperature alternates at regular intervals between periods of fever and periods of normal or subnormal temperatures.

Internal environment The physical, spiritual, cognitive, emotional, and psychologic well-being of an individual that depends on the satisfaction of these basic human needs.

Internal locus of control A belief that an individual can impact her or his own health and well-being.

Internet gaming disorder The persistent use of the internet to engage in games, often with other players, leading to clinically significant impairment or distress. May also be referred to as *internet gaming addiction*.

Interdisciplinary Referring to professionals or paraprofessionals from various disciplines.

Interorganizational conflict Usually conflict that occurs between two organizations that exist within one market.

Interpersonal conflict Conflict that occurs between two or more individuals due to differences, competition, or concern about territory, control, or loss.

Interpersonal violence Violence that occurs within relationships, between family members, intimate partners, acquaintances, or strangers that does not aim to further the goals of a formal group or cause.

Interprofessional Referring to professionals from multiple or various disciplines.

Interprofessional team A team that seeks to achieve a common goal, though the team members are professionals with varied backgrounds. Also called *interdisciplinary team*.

Intersex A general term used to describe a variety of conditions in which reproductive or sexual anatomy does not fit the typical definitions of male or female.

Interstitial fluid Accounts for approximately 75% of extracellular fluid; interstitial fluid surrounds the cells.

Intervention Activities conducted or attempts made by the nurse to influence a positive change in a patient's health status or behavior; a personalized confrontation that prevents an addict from denying the addiction problem and forces them to face the negative aspects of their behavior and enroll in treatment.

Intimacy A relationship that entails commitment, companionship, affective intimacy, social support, physical closeness, and mutuality.

Intimate distance Communication that is characterized by body contact, heightened sensations of body heat and smell, and vocalizations that are low.

Intimate partner violence (IPV) The act of inflicting sexual, emotional, or physical harm on a current or previous partner or spouse.

Intra-aortic balloon pump (IABP) Also called intra-aortic balloon counterpulsation, the IABP is a mechanical circulatory support device that may be used after cardiac surgery or to treat cardiogenic shock following AMI. The IABP temporarily supports cardiac function, allowing the heart to recover gradually by decreasing myocardial workload and oxygen demand and increasing perfusion of the coronary arteries.

Intracapsular hip fracture A hip fracture involving the head or neck of the femur.

Intracellular fluid (ICF) Fluid found within the body cells that contains solute vital to the metabolic processes of the cells. Also called *cellular fluid*.

Intracranial hypertension A sustained state of increased intracranial pressure that is potentially life threatening.

Intracranial regulation The processes that affect intracranial compensation and adaptive neurologic function.

Intractable seizures Seizures that continue to occur even with optimal medical management.

Intradiscal electrothermal therapy (IDET) The use of thermal energy to treat pain from a bulging spinal disc.

Intradisciplinary assessment An evaluation that occurs within a group of individuals with a similar position in the healthcare system, such as a group of nurses or a group of surgeons, to identify areas of improvement at each level of care.

Intradisciplinary team A team that seeks to achieve a common goal with team members from the same background.

Intergenerational family A family in which more than two generations live together.

Internal patients Employees of a healthcare organization, such as nurses, physicians, therapists, medical record staff, billing specialists, and other employees.

Intraocular pressure A force within the eye that causes tissue damage.

Intraoperative The phase of an operative process in which the surgical procedure actually takes place.

Intrapartum The time from the onset of true labor until the birth of the infant and expulsion of the placenta.

Intrapersonal conflict Conflict that occurs within an individual, arising from stress or tension that results from real or perceived pressure generated by incompatible expectations or goals.

Intrauterine contraception (IUC) A safe, effective method of reversible contraception that is designed to be inserted into the uterus by a qualified healthcare provider and left in place for an extended period, providing continuous contraceptive protection.

Intrauterine device (IUD) A small plastic or metal form that is placed in the uterus to prevent implantation of a fertilized ovum.

Intrauterine fetal death (IUFD) Death of a fetus that occurs after 20 weeks' gestation. Often referred to as *stillbirth* or *fetal demise*.

Intrauterine pressure catheter (IUPC) A device that measures the pressure in the uterine cavity.

Intravascular fluid Accounts for approximately 20% of the extracellular fluid and is found within the vascular system. Also called *plasma*.

Intravenous pyelography (IVP) A diagnostic test used to evaluate the structure and excretory function of the kidneys, ureters, and bladder.

Introspection The personal exploration and evaluation of one's own thoughts, emotions, behaviors, and values incorporating both verbal and nonverbal feedback from others.

Intubation The process of inserting a breathing tube.

Intuition The use of nursing knowledge, experience, and expertise for understanding without the conscious use of reasoning.

Invasion Occurs when cancerous cells overtake adjacent tissues.

Involuntary admission The detention of a patient in a psychiatric or medical facility against the patient's will, normally reserved for cases in which the patient is a danger to himself or others.

Involution The rapid reduction in size of the uterus and the return of the uterus to a nonpregnant state.

Ions Electrically charged particles.

Iron deficiency anemia A disorder that results when the supply of iron in the body is insufficient for the formation of red blood cells.

Irritant contact dermatitis An inflammation of the skin from irritants; it is not a hypersensitivity response.

Ischemia Insufficient blood supply.

Ischemic Deprived of oxygen.

Ischial spines Prominences that arise near the junction of the ilium and ischium and jut into the pelvic cavity.

Isoelectric line A straight line on an electrocardiograph that indicates the absence of electrical activity.

Isokinetic exercises Resistive exercises that involve muscle contraction or tension against resistance; can be either isotonic or isometric.

Isolation Measures designed to prevent the spread of infection to health personnel, patients, and visitors.

Isometric exercises Static or sitting exercises in which muscles contract without moving the joint.

Isotonic A solution that has the same osmolality as body fluids. Normal saline, 0.9% sodium chloride, is an isotonic solution.

Isotonic dehydration A type of fluid imbalance that occurs when fluid loss is not balanced by intake and the losses of water and sodium are in proportion. Also called *isotatremic dehydration*.

Isotonic exercises Dynamic exercises in which the muscle shortens to produce muscle contractions and active movement.

Isotonic fluid volume deficit A type of fluid imbalance that occurs when electrolytes are lost along with fluid.

Isotonic imbalance A fluid imbalance that occurs when water and electrolytes are lost or gained in equal proportions, so that the osmolality of body fluids remains constant.

Isthmus That portion of the uterus between the internal cervical os and the endometrial cavity.

Jaundice A yellow pigmentation of body tissues caused by the presence of bile pigments.

Joint arthroplasty The reconstruction or replacement of a joint.

Joint custody Occurs when two parents who are not married have equal responsibility and legal rights for their shared children.

Joint fusion A procedure that permanently fuses two or more bones together at a joint using pins, plates, screws, and rods. Also called *arthrodesis*.

Joint irrigation A fluid injected into the joint to allow the surgeon to visualize joint structures more easily and to help remove debris and infection in the joint.

Joint resurfacing A procedure in which a little bone is removed at the articulating surface of the joint and a metal replacement is fitted over the end of the bone.

Just culture An attempt to balance the blame-free environment with appropriate accountability by focusing on correcting problems that lead individuals to engage in unsafe behavior while maintaining individual accountability by establishing zero tolerance for reckless behavior.

Justice Fairness.

Juvenile glaucoma **Congenital glaucoma** diagnosed after age 3.

Juvenile idiopathic arthritis (JIA) See Juvenile rheumatoid arthritis (JRA).

Juvenile macular degeneration A pediatric form of **age-related macular degeneration** that is inherited rather than acquired.

Juvenile rheumatoid arthritis (JRA) A chronic inflammatory autoimmune disease diagnosed in children that is characterized by joint inflammation resulting in decreased mobility, swelling, and pain.

Kaposi sarcoma (KS) Often the presenting symptom of AIDS, it remains the most common cancer associated with the disease. Kaposi sarcoma is caused by a virus called the Kaposi sarcoma-associated herpes virus, also known as human herpes virus 8.

Kardex A widely used, concise method of organizing and recording data about a patient, making information quickly accessible to all healthcare professionals.

Karyotype A pictorial analysis of chromosomes.

Kcalorie See Kilocalories.

Kegel exercises The act of tightening the perineal muscle in order to strengthen the pubococcygeus muscle and increase its elasticity.

Keloid A scar that extends beyond the boundaries of the original wound.

Keratin A fibrous, water-repellent protein that gives the epidermis its tough, protective quality.

Keratotic basal cell carcinoma A type of skin cancer.

Ketonuria The presence of ketones in the urine.

Ketosis An accumulation of ketone bodies produced during oxidation of fatty acids.

Kilocalories A term used to identify the energy-producing ability of nutrients. Also called *Kcalories* or *kcal*.

Kindling Long-term changes in brain neurotransmission that occur after repeated detoxifications.

Kinesthesia The ability to perceive movement and sense of position.

Kinesthetic A term referring to awareness of the position and movement of body parts.

Korotkoff sounds The series of sounds identified while taking a blood pressure using a stethoscope.

Korsakoff psychosis A condition typically seen in alcoholics that is characterized by intact intellectual functioning but an inability to retrieve long-term memory events or retain new information.

Kosher Acceptable to or prepared according to Jewish law.

Kussmaul respirations Deep, rapid respirations associated with compensatory mechanisms.

Kyphosis A convex curvature of the spine that may decrease mobility.

Labor induction The stimulation of uterine contractions before the spontaneous onset of labor, with or without ruptured fetal membranes, for the purpose of accomplishing birth.

Labyrinthitis Inflammation of the inner ear. Also called *otitis interna*.

Laceration Disruption of the brain tissue caused by the entrance of a foreign object such as a bullet, knife, or skull fragment.

Lactase deficiency An individual's inability to digest lactose because of a deficiency of lactase, the enzyme that breaks down lactose into monosaccharides. Also called *lactose intolerance*.

Lactation consultant A specially trained individual who provides breastfeeding support and care to mothers, infants, children, families, and communities.

Lacto-ovovegetarians Vegetarians who include milk, dairy products, and eggs in their diets.

Lactase deficiency Occurs when the body lacks that substance that triggers the chemical breakdown to metabolize lactose.

Lactose intolerance An individual's inability to digest lactose because of a deficiency of lactase, the enzyme that breaks down lactose into monosaccharides. Also called *lactose deficiency*.

Lactovegetarians Vegetarians who include dairy products but no eggs in their diets.

Laënnec cirrhosis A progressive, irreversible liver disorder resulting from excessive alcohol consumption. Also called *alcoholic cirrhosis*.

Laissez-faire leader A leader who recognizes a group's need for autonomy and self-regulation. The leader assumes a "hands-off" approach, being less directive and more permissive than other types of leaders.

Lamellar A type of bone that is stronger and more compact with better blood circulation compared to woven bone.

Laminectomy The surgical removal of the vertebral lamina.

Laminotomy The surgical removal of part of the vertebral lamina.

Lanugo A large quantity of fine hair found on some newborns.

Laparoscopic cholecystectomy Removal of the gallbladder using an endoscope.

Late deceleration A condition caused by uteroplacental insufficiency resulting from decreased blood flow and oxygen transfer to the fetus through the intervillous spaces during uterine contractions.

Late (secondary) postpartum hemorrhage Postpartum hemorrhage that occurs from 24 hours to 6 weeks after birth.

Law The sum total of the rules and regulations by which a society is governed.

Laxatives Medications that stimulate bowel activity and assist in fecal elimination.

Lead An insulated wire that connects an electrocardiograph to the electrodes attached to a patient.

Leader An individual with the ability to rule, guide, or inspire others to think or act as that individual recommends.

Leading question A closed question that gives the patient an opportunity to decide whether the answer is true or not.

Lean Six Sigma A methodology used to reduce waste and provide consistency in the quality of care.

Learned helplessness A sense of helplessness that nothing the individual does can change an aspect of a situation or stressor; often reinforced by repeated failures, learned helplessness is common in individuals with major depressive disorder.

Learning A change in human disposition or capability that persists and that cannot be solely accounted for by growth.

Learning disabilities Disorders that impair an individual's ability to receive and process information, causing reduced functioning in verbal, linguistic, reasoning, and academic skills; neurologic conditions in which the brain cannot receive or process information normally.

Learning need A desire or a requirement to know something that is presently unknown to the learner.

Lecithin/sphingomyelin (L/S) ratio The measurement of lecithin and sphingomyelin in order to determine the lung maturity of a fetus.

Leopold maneuvers A systematic way to evaluate the maternal abdomen.

Lesbian A woman who prefers relationships with other women.

Lesion An observable change in skin structure that may indicate disorders in other systems and organs.

Leukemia A group of chronic malignant disorders of white blood cells (WBCs) and WBC precursors.

Leukocytes The primary cells involved in both nonspecific and specific immune system responses. Also known as *white blood cells (WBCs)*.

Leukocytosis An increase in the number of leukocytes in the blood (above 10,000/mm³), in response to infection or inflammation.

Leukopenia A decrease in the number of circulating leukocytes.

Level of injury The vertical location of an injury along the spinal column.

Lewy bodies Abnormal aggregates of proteins, including alpha-synuclein.

Liability The state of being legally obliged and responsible.

Libido Sexual desire.

Licensed practical nurses (LPNs) Members of a nursing team who provide direct patient care under the direction of an RN, physician, or other licensed practitioner.

Lichenification The thickening of the skin.

Lifestyle An individual's general way of living, including living conditions and individual patterns of behavior that are influenced by sociocultural factors and personal characteristics.

Ligaments Connective tissue between bones to create joints.

Lightening The effects that occur when the fetus begins to settle into the pelvic inlet.

Limb restraints A device typically made of cloth that may be used when limb immobilization is needed for therapeutic purposes, for example, to prevent dislodgement of an intravenous infusion device.

Limbic system A set of structures located deep inside the brain; includes the hippocampus.

Limit setting Establishing clear and consistent rules or guidelines for child or patient behavior.

Line authority The power to direct the activities of subordinates within an organization.

Lipids The macronutrient that provides most of the body's energy at 9 kcal/g. There are three categories of lipids: triglycerides, phospholipids, and sterols. Also called *fats*.

Lipoatrophy Atrophy of subcutaneous tissues.

Lipodystrophy Excessive growth of subcutaneous tissue.

Lithiasis Stone formation.

Lithotripsy The preferred treatment for urinary calculi; uses sound or shock waves to crush a stone.

Living will A document that provides written directions about life-prolonging procedures to provide instructions when an individual can no longer communicate in a life-threatening situation.

Lobes Specialized cognitive regions in the hemispheres of the brain.

Local adaptation syndrome (LAS) A stress response that affects only one organ or body system.

Local emergency management agency (LEMA) A governmental agency with expertise in public safety, emergency medical services, and management.

Local infection Invasion by a microorganism that is limited to the specific part of the body where the microorganism remains.

Localized responses Common manifestations of type I hypersensitivity, they are typically atopic responses; that is, they have a strong genetic predisposition. Atopic reactions are the result of localized, rather than systemic, IgE-mediated responses to an allergen. They are prompted by contact of the allergen with IgE in the bronchial tree, nasal mucosa, and conjunctival tissues.

Lochia The discharge through which the uterus rids itself of the debris remaining after birth. The discharge should change appearance and contents as healing commences.

Lochia alba The final discharge as the uterus completes healing; composed primarily of leukocytes, decidual cells, epithelial cells, fat, cervical mucus, cholesterol crystals, and bacteria.

Lochia rubra The dark red initial discharge as the uterus eliminates epithelial cells, erythrocytes, leukocytes, shreds of decidua, and occasionally fetal meconium, lanugo, and vernix in the first 1–2 days following birth.

Lochia serosa A light pink discharge of serous exudate, shreds of degenerating decidua, erythrocytes, leukocytes, cervical mucus, and numerous microorganisms from the uterus 3–10 days following birth.

Locked-in syndrome A state of consciousness in which the patient is alert and fully aware of the environment and has intact cognitive abilities but is unable to communicate through speech or movement because of blocked efferent pathways from the brain. Motor paralysis affects all voluntary muscles, although the upper cranial nerves (I through IV) may remain intact, allowing the patient to communicate through eye movements and blinking.

Locus of control (LOC) The extent to which patients believe their health status is under their own or others' control.

Long-term memory The final process or destination for information to be stored indefinitely.

Longboard spinal immobilization A device that provides support and immobilization of the entire spine below the level of the neck, instituted for patients with a potential or suspected spinal cord injury from a motor vehicle collision.

Loose association An indication of disordered thinking characterized by the shifting of verbal ideas from one topic to another, with no apparent relationship between thoughts, and the person speaking being unaware that the topics are unconnected. Commonly seen in schizophrenia.

Lordosis A concave curvature of the spine that may decrease mobility.

Loss A situation in which someone or something that is valued becomes altered or no longer available.

Lower body obesity Identified by a waist-to-hip ratio of less than 0.8; more commonly seen in women. Also called *peripheral obesity*.

Lumpectomy Removal of a tumor and the surrounding margin of breast tissue followed by radiation therapy. Also called *segmental mastectomy* or *breast conservation surgery*.

Lung abscess A local area of necrosis and pus formation within the lung.

Lupus nephritis Inflammation of the kidneys resulting from systemic lupus erythematosus (SLE).

Luteinizing hormone (LH) Anterior pituitary hormone responsible for stimulating ovulation and for development of the corpus luteum.

Lymphadenopathy The enlargement of lymph nodes with or without tenderness. It may be caused by inflammation, infection, or malignancy of the nodes or the regions drained by the nodes.

Lymphangitis Inflammation of a lymph vessel.

Lymphedema Accumulation of fluid in the soft tissues of the arm caused by removal of lymph channels.

Lymphocytes The principal effector and regulator cells of specific immune responses to protect the body from microorganisms, foreign tissue, and cell mutations or alterations.

Lyse Disintegrate.

Maceration Tissues softened by prolonged wetting or soaking.

Macronutrients Essential nutrients needed by the body in large amounts to survive: carbohydrates, proteins, and fats.

Macrophages Large phagocytes that are important in the body's defense against chronic infections.

Macular degeneration A progressive disorder involving loss of central vision due to damage to the retina.

Magical thinking Believing that events occur because of one's thoughts or actions.

Major depressive disorder (MDD) A mood disorder characterized by loss of interest in life and unresponsiveness, moving from mild to severe, with severe symptoms lasting at least 2 weeks. Also called *unipolar depression*.

Major depressive episode Characterized by a change in several aspects of an individual's emotional state and functioning consistently over a period of 14 days or longer.

Major trauma A serious single-system injury (such as the amputation of a leg) or multiple-system injuries (simultaneous injuries such as a punctured lung, traumatic brain injury, and crushed bones in the arms and legs). Also called *multisystem trauma*.

Malabsorption A condition in which the intestinal mucosa is unable to absorb nutrients, resulting in nutrients being excreted in the stool.

Malaise Vague feeling of physical discomfort.

Maldigestion A condition in which there is inadequate preparation of chyme for absorption of nutrients; also can result in malabsorption.

Male hypoactive sexual desire disorder A deficiency in or absence of sexual fantasies and persistently low interest or a total lack of interest in sexual activity.

Male orgasmic disorder A condition that occurs when a man can maintain an erection for long periods, but has difficulty ejaculating.

Malignant Term used to refer to a cell or growth that, if not treated, will recur, continue to grow, and spread to other sites in the body, ending in death.

Malignant hyperthermia A musculoskeletal disorder resulting from an inherited cellular deficit that places the patient in a hypermetabolic state.

Malnutrition Health effects due to insufficient nutrient intake or stores. Also called *undernutrition*.

Malpractice Conduct deviating from the standard of practice dictated by a profession.

Malpresentation A condition that occurs when a fetus passes into the pelvic inlet with a breech or shoulder presentation. These presentations are associated with difficulties during labor.

Malunion The healing of bones in an anatomically incorrect position. Surgical correction may be needed.

Managed care A healthcare delivery system designed to provide cost-effective, high-quality care for groups of patients from the time of their initial contact with the health system through the conclusion of their health problem.

Manager An individual employed by an organization and granted the required authority, responsibility, accountability, and power to accomplish the organization's goals.

Mandatory health insurance Health insurance is provided by large, nonprofit health organizations centered around large employers or work-based associations or else is provided by government-sponsored programs. Everyone belongs to one of these two types of insurance plans, thus ensuring universal coverage.

Mandatory reporting A legal requirement to report an act, event, or situation that is designated by state or local law as a reportable event.

Mania An abnormal and persistently elevated, expansive, or irritable mood lasting at least 1 week, significantly impairing social or occupational functioning and generally requiring hospitalization.

Manipulation Controlling behavior used to exploit others for personal gain.

Margination The accumulation of leukocytes along the inner surface of blood vessels. Occurs as part of the inflammatory process.

Marital rape Rape that occurs when one spouse forces the other to have sex against his or her will.

Maslow's hierarchy of needs A concept proposed by Abraham Maslow in which he proposed the existence of levels of human needs that could be organized into five categories: physiologic, safety, love and belonging, esteem, and self-actualization.

Massage therapy The scientific manipulation of the soft tissues of the body for the purposes of promoting healing and wellness.

Massive transfusion A series of blood parcels, including packed red blood cells, fresh frozen plasma, cryo units, and platelet pheresis administered to a patient who has lost a substantial amount of blood.

Mast cells Leukocytes that detect foreign agents or injury and respond by releasing histamine, thereby activating the inflammatory process.

Masturbation The self-stimulation of one's genitals for sexual pleasure.

Maternal role attainment (MRA) The process by which a woman learns mothering behaviors and becomes comfortable with her identity as a mother.

Maturation crisis A crisis that occurs normally as an individual progresses through the life cycle.

Mature milk A white or slightly blue-tinged color milk that presents by 2 weeks postpartum and continues thereafter until lactation ceases.

McDonald sign A probable sign of pregnancy characterized by an ease in flexing the body of the uterus against the cervix.

Mean arterial pressure (MAP) The average pressure in the arterial circulation throughout the cardiac cycle.

Meaning-focused coping The use of reevaluation to reduce the appraisal of a threat.

Meatus A body passage or opening.

Meconium The first fecal material passed by a newborn, normally within 8–24 hours after birth.

Medicaid A state-administered health insurance program available to certain lower-income individuals and families, older adults, and people with disabilities.

Medical asepsis All practices intended to confine a specific microorganism to a specific area, thus limiting the number, growth, and transmission of the microorganism.

Medicare A federally funded health insurance program available to people ages 65 or older, younger people with disabilities, and people with end-stage renal disease.

Medigap policy A private health insurance plan designed to supplement Medicare coverage. It may pay copayments, coinsurance, deductibles, and “gaps” in Medicare coverage (i.e., noncovered healthcare costs). Also called *Medicare supplemental insurance*.

Meditation The act of focusing one's thoughts or engaging in self-reflection or contemplation.

Meiosis A reductive division of sex cells, producing ova or sperm with a half set (haploid) of chromosomes.

Melanin A shield that protects the keratinocytes and the nerve endings in the dermis from the damaging effects of ultraviolet light.

Melanoma A type of malignant skin cancer.

Melasma gravidarum See Chloasma.

Mendelian inheritance Traits that are passed on by a single gene. Also called *single-gene inheritance*.

Meninges Three connective tissue membranes that cover, protect, and nourish the central nervous system.

Menometrorrhagia Irregular, excessive, prolonged menstruation.

Menopause The permanent cessation of menses.

Menorrhagia Excessive or prolonged menstruation that occurs at regular intervals.

Menstrual cycle The cyclic phases of menstruation that normally occur about every 28 days.

Menstruation The periodic shedding of the uterine lining in a woman of childbearing age who is not pregnant.

Mental health A state of well-being in which an individual is able to work productively, cope with change and adversity, engage in meaningful relationships, and realize his own potential.

Mental illness A condition that affects emotions, thinking, behavior, or any combination of the three; mental illness is characterized by symptoms that are severe enough to impair functioning.

Mental retardation See Intellectual disability.

Mentor A competent, experienced professional who develops a relationship with a novice for the purpose of providing advice, support, information, and feedback in order to encourage development of the individual.

Message Content that is actually said or written, the body language that accompanies the words, and how the words are transmitted.

Metabolic acidosis This bicarbonate deficit is characterized by a low pH (<7.35), low bicarbonate (<24 mEq/L), and PaCO₂ less than 38 mmHg. It may be caused by excess acid in the body or loss of bicarbonate from the body.

Metabolic alkalosis This bicarbonate excess is characterized by a high pH (>7.45), a high bicarbonate (>28 mEq/L), and PaCO₂ higher than 45 mmHg. It may be caused by loss of acid or excess bicarbonate in the body.

Metabolic syndrome A disorder characterized by the presence of three or more of the following: increased waist circumference, hypertension, elevated blood triglycerides and fasting blood glucose, and low HDL cholesterol.

Metabolism The complex process of biochemical reactions occurring in the body's cells necessary to produce energy, repair cells, and sustain life.

Metacognition The human ability to think about thinking.

Metaphysis The portion of the bone between the diaphysis and the epiphysis.

Metaplasia A change in the normal pattern of differentiation such that dividing cells differentiate into cell types not normally found at that location in the body.

Metastasis The process by which spreading of malignant neoplasms occurs; the transfer of disease from one organ or part to another.

Metrorrhagia Bleeding between menstrual periods.

Microalbuminuria An abnormally low level of albumin in the urine.

Micronutrients Essential nutrients needed by the body in small quantities, such as vitamins and minerals.

Microstaging The assessment of the level of invasion of a malignant melanoma and the maximum tumor thickness.

Micturition Releasing urine from the urinary bladder. Also called *voiding* or *urination*.

Middle ear effusion Results when negative pressure in the middle ear causes sterile serous fluid to move from the capillaries into the space.

Milia Exposed sebaceous glands that appear as raised white spots on the face, especially across the nose on infants within the first month after birth.

Miliary tuberculosis Results from hematogenous spread (through the blood) of the tuberculosis bacilli throughout the body.

Milieu therapy A therapeutic recovery environment that supports behavior changes, teaches new coping skills, and helps the patient move from addiction to sobriety.

Milliequivalent The chemical combining power of the ion, or the capacity of cations to combine with anions to form molecules.

Minerals Salts dissolved in water that carry electrical charge and work with other nutrients to maintain fluid balance throughout the body. Also called *electrolytes*.

Minimal enteral nutrition Small-volume feedings of formula or human milk (usually <24 mL · kg⁻¹ · day⁻¹) designed to “prime” the premature infant's intestinal tract and stimulate many of its hormonal and enzymatic functions.

Minor trauma Trauma that affects a single part or system of the body and is usually treated in a physician's office or in a hospital's emergency department.

Miscarriage The loss of a fetus prior to 20 weeks' gestation. Also called a *spontaneous abortion*.

Mitigation A phase that takes place before and after an emergency that consists of identifying potential hazards, minimizing effects, and reducing the likelihood of their occurrence.

Mitosis The process of cell division.

Mitt restraints A device used to protect confused patients from scratching or injuring their skin or dislodging intravenous access devices. Also called *hand restraints*.

Modeling Observing the behavior of people who have successfully achieved a goal that they have set for themselves and, through observing, acquiring ideas for behavior and coping strategies.

Modified radical mastectomy The removal of the breast tissue and lymph nodes under the arm, leaving the chest wall muscles intact.

Molding The asymmetrical appearance of an infant's head caused by overlapping of the cranial bones during labor and birth.

Mongolian spots Macular areas of bluish-black or gray-blue pigmentation on the dorsal area and the buttocks; common in newborns of Asian, Hispanic, and African descent and in newborns of other dark-skinned races.

Monoamine oxidase inhibitor (MAOI) A drug that inhibits monoamine oxidase, an enzyme that terminates the actions of neurotransmitters such as dopamine, norepinephrine, epinephrine, and serotonin. These drugs are used to treat individuals who have not responded to typical treatments for depression.

Mononeuropathies Isolated peripheral neuropathies that affect a single nerve.

Monophasic A term used to describe rheumatoid arthritis when it occurs for a limited time and then improves.

Monopolizing The domination of a discussion by one member of a group.

Monosomy Absence of a chromosome.

Monro-Kellie hypothesis A hypothesis that states if the volume of any of the three intracranial components (the brain, cerebrospinal fluid, and blood) increases, the volume of the others must decrease to maintain normal pressures in the cranial cavity.

Mood An individual's internal, subjective, sustained emotional state.

Mood stabilizers Drugs used for treatment of bipolar disorder because they moderate extreme shifts in emotions between mania and depression.

Moral behavior The way in which an individual perceives and responds to society's requirements.

Moral development 1. The process of learning to tell the difference between right and wrong and of learning what ought and ought not to be done. 2. The pattern of change in moral behavior that occurs with age.

Moral principles Statements about broad, general, philosophical concepts such as autonomy and justice.

Moral rules Specific prescriptions for actions.

Morality Private, personal standards of what is right and wrong in conduct, character, and attitude; the requirements necessary for people to live together in society.

Morbid obesity A condition in which an individual weighs more than 200% of his or her ideal body weight or has a BMI >40 kg/m².

Morning sickness A term that refers to the nausea and vomiting that a woman may experience in early pregnancy. This lay term is sometimes used because these symptoms frequently occur in the early part of the day and disappear within a few hours.

Moro reflex In response to being lifted, then suddenly lowered or surprised by a loud noise, a newborn will straighten the arms and hands outward while the knees flex. Slowly, the arms return to the chest, as in an embrace. The fingers spread, forming a "C," and the newborn may cry.

Morpheaform basal cell carcinoma A type of skin cancer.

Morula Developmental stage of the fertilized ovum in which there is a solid mass of cells.

Mosaicism The expression of two cell lines, each with a different chromosomal number, in an individual.

Motility The process of moving food and fluid through the gastrointestinal tract from the mouth to the anus.

Motivation to learn The individual's personal desire and need to learn that affects how much and how fast the individual will learn.

Motor vehicle crash (MVC) The unintentional collision of one or more motor vehicles with another vehicle or object.

Mottling A lacy pattern of dilated blood vessels under the skin.

Mourning The behavioral process through which grief is eventually resolved or altered; it is often influenced by culture, spiritual beliefs, and custom.

Movement disorder A disorder associated with schizophrenia. There are two general forms: The first involves increased body movements that may appear agitated, repetitious, or purposeless. The second form involves catatonia, or unresponsiveness to the environment or others.

Movement technique A relaxation technique, such as yoga or tai chi, designed to improve strength, balance, and mental calmness.

Mucolytics Medications that help break up thick mucus secretions in the airways.

Multi-payer system Healthcare insurance coverage or payment system in which funds come from multiple sources.

Multiculturalism Characterized by many subcultures coexisting within a given society in which no one culture dominates.

Multidisciplinary team approach An approach to healthcare in which team members work together to deliver patient care, but a single team member—usually a physician—makes the treatment decisions.

Multifocal A term used to describe premature ventricular contractions (PVCs) that arise from different ectopic sites and appear distinct on the ECG.

Multigravida Term used to describe a woman who has been pregnant more than once.

Multipara Term used to describe a woman who has had more than one pregnancy in which the fetus was viable.

Multiple pregnancy More than one fetus in the uterus at the same time.

Multiple sclerosis (MS) A chronic demyelinating neurologic disease of the central nervous system associated with an abnormal immune response to an environmental factor.

Multiple trauma Trauma that involves serious single-system injury or multiple-system injuries. Also called *major trauma*.

Mural thrombi Blood clots in the heart wall.

Muscle relaxation A relaxation technique that involves consciously tightening and then relaxing each muscle progressively from either head to toe or toe to head.

Mutual recognition model A licensing system that allows a nurse to have a single license that confers the privilege to practice in other states that are part of the Nurse Licensure Compact.

Mutual respect A state in which two or more individuals show or feel honor or esteem toward one another.

Mycobacterium tuberculosis The bacteria that causes tuberculosis.

Mydriasis Abnormal or excessive dilation of the pupil of the eye, usually caused by a disease or drug.

Myelin The fatty, segmented wrappings that normally protect and insulate nerves. Also called *myelin sheath*.

Myelogram A diagnostic technique in which dye is injected into the spinal fluid and visualized by x-ray in order to identify areas of pressure on the spinal cord or nerves due to herniated discs.

Myocardial hypertrophy An increase in the size of muscle cells of the myocardium.

Myometrium The middle muscular layer of the uterus.

Myopia Nearsightedness.

MyPlate A nutrient intake guide from the U.S. Department of Agriculture that outlines suggested food intake by food groups.

Myringotomy A surgical incision of the tympanic membrane.

Myxedema The hypothyroid state with characteristic accumulation of nonpitting edema in the connective tissues throughout the body.

Myxedema coma A life-threatening complication of long-standing, untreated hypothyroidism, usually triggered by an acute illness or trauma.

Nägele rule A common method of determining the estimated date of birth using the first day of the last menstrual period, subtracting 3 months, and adding 7 days.

NANDA The acronym for North American Nursing Diagnosis Association.

Narcissism Self-centered behavior in which the individual feels entitled to special favors due to a mistaken perception that they are superior to others.

Narcissistic personality disorder (NPD) One of several personality disorders defined in the DSM-5, it is marked by in a pattern of grandiosity, difficulty regulating self-esteem, and the need for admiration and attention from others.

Narcolepsy A disorder characterized by daytime sleep attacks or excessive daytime sleepiness.

Narcotics See Opioids.

Narrative charting A traditional part of the source-oriented record. It consists of written notes that include routine care, normal findings, and patient problems.

National Institute for Occupational Safety and Health (NIOSH) An organization that focuses on generating new knowledge in the field of occupational safety and health and transferring that knowledge into practice for the betterment of workers.

National Patient Safety Goals (NPSGs) Formulated goals to assist accredited organizations with specific topics about patient safety.

Natural killer (NK) cells Large, granular cells found in the spleen, lymph nodes, bone marrow, and blood. NK cells provide immune surveillance and resistance to infection, and they play an important role in the destruction of early malignant cells.

Nature The genetic or hereditary capability of the individual.

Nausea A vague, but unpleasant, subjective sensation of sickness or queasiness.

Necrosis Dead tissue.

Negative affectivity One of the six trait domains associated with personality disorders that is distinguished by anxiousness, emotional lability, separation insecurity, depressive tendencies, perseveration, and suspicion.

Negative airflow room A room where airflow is controlled to prevent the air from circulating into the hallway or other rooms. Multiple fresh-air exchanges dilute the concentration of droplet nuclei in a negative airflow room. Also called *negative flow room*.

Negative feedback Output of a system that returns to the system as input and which inhibits system change.

Negative pressure ventilators A device that creates negative pressure externally to draw the chest outward and air into the lungs, mimicking spontaneous breathing.

Negative punishment The removal of a positive reward if an undesirable behavior occurs.

Negative symptom Loss or absence of a normal function seen in mentally healthy adults, such as the ability to care for one's self; commonly seen in schizophrenia.

Neglect syndrome A disorder of attention that can result from stroke, which is characterized by the inability to integrate and use perceptions from the affected side. Also called *unilateral neglect*.

Negligence Any conduct that deviates from what a reasonable person would do in a particular circumstance.

Neologisms Use of meaningless words that only have meaning to the individual using them.

Neonatal abstinence syndrome (NAS) A combination of neonatal signs and symptoms caused by withdrawal of gestational opioid exposure.

Neonatal anemia A disorder caused by blood loss, hemolysis, and impaired red blood cell production related to birth.

Neonatal mortality risk An infant's chance of death within the first 28 days of life.

Neonatal transition The first few hours after birth, in which a newborn's body systems adapt to extrauterine life.

Neonatology The field of medicine providing care for sick and premature infants.

Neoplasm A mass of new tissue that grows independently of its surrounding structures and has no physiologic purpose.

Nephrectomy Removal of a kidney.

Nephritis Inflammation of the kidneys.

Nephrolithiasis The formation of stones in the kidney.

Nephrolithotomy A procedure for removal of a staghorn calculus that invades the calyces and renal parenchyma.

Nephrotoxins Substances that damage nerves or nerve tissue.

Nerve block A chemical interruption of a nerve pathway, effected by injecting a local anesthetic into the nerve.

Networking The act of developing and maintaining relationships with others within and outside of the nursing profession and affiliated organizations to improve nursing practice, advance career goals, offer support, share information, and provide advice.

Neurofibrillary tangles Seen in patients with Alzheimer disease, they are thick, insoluble clots of protein inside the damaged brain cells or neurons.

Neurogenic bladder Interference with the normal mechanisms of urine elimination in which the patient does not perceive bladder fullness and is unable to control the urinary sphincters; usually the result of impaired neurologic function.

Neurogenic shock The result of an imbalance between parasympathetic and sympathetic stimulation of vascular smooth muscle.

Neuroleptic malignant syndrome (NMS) A potentially fatal condition caused by antipsychotic medications that block dopamine receptors. It is characterized by fever, rigidity, and increased prolactin levels.

Neuron The basic or specialized cell of the nervous system that carries electrical impulses throughout the body.

Neuropathic pain A type of pain experienced by people who have damaged or malfunctioning nerves.

Neurotransmitters Chemical messengers that carry information between neurons.

Neutral question An open-ended question the patient can answer without direction or pressure.

Neutral thermal environment (NTE) A specific environmental temperature range in which the rates of oxygen consumption and metabolism are minimal and the internal body temperature is maintained because of thermal balance.

Never events Preventable hazards that can result in injury or death, and that should never happen to patients.

Nevi Moles.

Nevus flammeus A capillary angioma directly below the epidermis. It is a nonelevated, sharply demarcated, red-to-purple area of dense capillaries. In infants of African descent, it may appear as a purple-black stain. Also called *port-wine stain*.

Nevus vasculosus A capillary hemangioma consisting of newly formed and enlarged capillaries in the dermal and subdermal layers. It is a raised, clearly delineated, dark red, rough-surfaced birthmark commonly found in the head region. Also called a *strawberry mark*.

New Ballard score Specific criteria designed for accurate assessment of the gestational age of newborns between 20 and 28 weeks of gestation and weighing less than 1500 g.

Newborn Infant from birth through the first 28 days of life.

G-34 Glossary

Nicotine A highly addictive chemical that is found in tobacco and enters the body via the lungs (cigarettes, pipes, and cigars) and oral mucous membranes (chewing tobacco as well as smoking).

Nicotine replacement therapy (NRT) A pharmacologic therapy designed to relieve some of the physiologic effects of withdrawal, including cravings, for patients trying to quit smoking or using tobacco. NRT transdermal patches and gums are available over the counter; nicotine inhalers and nasal sprays are available by prescription only.

Nicotinic receptors Found in the hippocampus and involved with new sensory information and memory formation, they are thought to be impaired in patients with schizophrenia.

Nidation The cyclical preparation of the uterine lining by steroid hormones for implantation of the embryo.

Nociceptive pain A type of pain resulting from external stimuli on an uninjured, fully functional nervous system.

Nociceptors The nerve receptors for pain.

Nocturia Voiding two or more times at night.

Nocturnal emissions Orgasm and emission of semen during sleep. Also called *wet dreams*.

Nocturnal enuresis Involuntary urination at night after bladder control has been achieved. Also called *bed wetting*.

Nocturnal frequency The need for older adults to arise during the night to urinate.

Nodular basal cell carcinoma A type of skin cancer.

Noise-induced hearing loss (NIHL) A condition associated with prolonged exposure to sound of greater than or equal to 85 dB.

Nolo contendere A term used when an individual neither admits to nor denies committing a crime but agrees to a punishment as if guilty.

Nominal group technique (NGT) A process that alternates between individual work and group work. Individuals meet as a group, but they write their responses without any discussion.

Nondirective interview An unstructured interview in which the nurse allows the patient to control the purpose, subject matter, and pacing.

Nonexudative macular degeneration The most common form of macular degeneration, it is characterized by the accumulation of deposits beneath the pigment epithelium of the retina, causing the pigment epithelium to detach and interfere with the sensory function of the macula. Also referred to as the dry form of macular degeneration.

Noninvasive ventilation (NIV) Ventilator support using a tight-fitting face mask, thus avoiding intubation.

Nonmaleficence The duty to do no harm.

Non-Mendelian inheritance Traits that are passed on by the influence of multiple genes. Also called *multifactorial inheritance*.

Nonpenetrating injury Also called a close injury, this type of injury is associated with blunt-force injuries that do not result in the entrance of a foreign object into the body.

Nonshivering thermogenesis (NST) The stimulation of heat production in the body through increased cellular metabolism. Also called *chemical thermogenesis*.

Non-small-cell carcinoma Lung cancers other than small-cell carcinoma.

Nonstress test (NST) A widely used method of evaluating fetal status; may be used alone or as part of a more comprehensive diagnostic assessment called a biophysical profile.

Non-suicidal self-injury behaviors (NSSI) Intentional self-inflicted acts of harm to body tissue without the intent of suicide.

Nonunion Failure of the ends of a fracture to heal together after at least 3 months.

Nonverbal communication Transmitting information through gestures, facial expressions, or touch.

Normal sinus rhythm (NSR) The normal heart rhythm, in which impulses originate in the sinus node and travel through all normal conduction pathways without delay.

Normative commitment A feeling of obligation to continue in the profession due to benefits or positive experiences derived from the profession.

Normothermia Normal body temperature.

Nosocomial infections Infections that are associated with the delivery of healthcare services in a facility such as a hospital or nursing home. Also called *healthcare-associated infections (HAIs)*.

NREM Sleep Non-rapid-eye-movement sleep occurs when activity in the *reticular activating system* is inhibited.

Nuclear family A family structure consisting of a husband and wife and their biological children.

Nucleation The formation of a crystal from a liquid.

Nucleotomy The surgical removal of a herniated disc.

Nulligravida Term used to describe a woman who has never been pregnant.

Nullipara Term used to describe a woman who has not given birth to a viable fetus.

Nurse practice act (NPA) State-level statutes that define and regulate nursing practices.

Nursing clinical research Research that seeks to answer questions that ultimately will improve patient care.

Nursing diagnosis A clinical judgment about individual, family, or community responses to actual and potential health problems/life processes.

Nursing ethics Ethical issues that occur in nursing practice.

Nursing informatics (NI) A specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, knowledge, and wisdom in nursing practice.

Nursing plan of care A written or electronic guideline that organizes information about an individual patient's or family's care.

Nursing process The process used to identify a patient's health status and actual or potential healthcare problems or needs, to establish plans to meet the identified needs, to deliver specific nursing interventions to meet those needs, and to evaluate the success of those interventions.

Nursing research A systematic and strict scientific process that tests hypotheses about health-related illness and conditions and processes of nursing care practices.

Nursing transactional model The relationship among the nurse, the patient, and the environment in which they interact.

Nurture The effects of the environment on an individual's performance.

Nutrient density The ratio of good nutrients to calories a food contains.

Nutrients Substances found in food used by the body to promote growth, maintenance, and repair.

Nutrition The process by which the body ingests, absorbs, transports, uses, and eliminates nutrients in food.

Nutritional health The physical result of the balance between nutrient intake and nutritional requirements.

Nystagmus Involuntary rapid eye movement.

Obesity An excess of adipose tissue.

Object permanence The ability to understand that when something is out of sight it still exists.

Objective data Information that is detectable by an observer or can be measured or tested against an accepted standard. Also called *overt data* or *signs*.

Objective family burden Actual, identifiable family problems associated with the mental illness of a family member.

Obligatory losses Essential fluid losses required to maintain body functioning.

Observational learning The acquisition of new skills or the alteration of old behaviors simply by watching other children and adults.

Obsession A recurrent, unwanted, and often distressing thought or image that leads to feelings of fear and anxiety.

Obsessive-compulsive disorder (OCD) A disabling disorder characterized by obsessive thoughts and compulsive, repetitive behaviors that dominate an individual's life.

Obsessive-compulsive personality disorder (OCPD) One of several personality disorders defined in the DSM-5, it is marked by fear and anxiety concerning loss of control over situations, objects, or people.

Obstetric conjugate The distance from the middle of the sacral promontory to an area approximately 1 cm below the pubic crest.

Obstructive shock Shock caused by an obstruction in the heart or great vessels that either impedes venous return or prevents effective cardiac pumping action.

Occult blood Blood in stool that cannot be seen with the naked eye.

Occupational exposure Skin, eye, mucous membrane, or parenteral contact with blood or other potentially infectious materials that may result from the performance of an employee's duties.

Occupational Safety and Health Administration (OSHA) An organization that enforces the guidelines presented in the OSHA Act of 1970, requiring its covered employees to report specific incidents and illnesses in a timely manner.

Oculocephalic reflex An oculomotor response in which the eyes move in opposite direction as head turns to the side. Also called **doll's eye reflex**.

Olfactory Of or relating to smell.

Oligodendrocytes Cells that produce myelin.

Oligomenorrhea Light or infrequent menstruation and occurs when cycles are longer than 6–7 weeks. Usually related to hormonal imbalances such as those seen in polycystic ovary syndrome.

Oliguria The production of abnormally small amounts of urine by the kidney.

On-off effect A sudden lack of symptom control and unexpected dyskinesias appearing as drug effectiveness diminishes.

Oncogenes Genes that promote cell proliferation and are capable of triggering cancerous characteristics.

Oncology The study of cancer.

Oncotic pressure A pulling force exerted by colloids that helps maintain the water content of blood by pulling water from the interstitial space into the vascular compartment. Also called *colloid osmotic pressure*.

Online shopping addiction Excessive online shopping, often associated with overspending and aided by the internet, and characterized by compulsive and addictive forms of consumption and buying behavior.

Oogenesis The process that produces the female gamete, called an ovum (egg).

Open-angle glaucoma The most common form of glaucoma, it is a chronic, gradually progressive disease that typically affects both eyes.

Open-ended question A question that allows patients to discover, explore, elaborate, clarify, or illustrate their thoughts or feelings.

Open fracture A fracture in which the skin integrity is disrupted. Also called a *compound fracture*.

Open reduction and internal fixation (ORIF) The surgical insertion of nails, screws, plates, or pins to hold fractured bones in place.

Opiates A type of drug derived from natural or synthetic opiates that is used as a pain reliever. Opiates include morphine, meperidine, codeine, hydrocodone, and oxycodone.

Opioids Drugs that act on one or more of three opioid receptors: mu, delta, and kappa. They are controlled substances due to their potential for abuse. Also called *narcotics*.

Opportunistic infection An invasion of the body tissue by microorganisms appearing in an individual with immunodeficiency that would normally not affect an individual with an intact immune system.

Opportunistic pathogen A microorganism that causes disease only in susceptible individuals.

Optimism A feeling that things will turn out for the best.

Oral-genital sex Kissing, licking, or sucking of the genitals for sexual pleasure.

Orchiectomy Surgical removal of the testes.

Organizational chart A chart that depicts the formal hierarchical structure and related responsibilities within a traditional organization.

Organizational commitment The relative strength of an individual's relationship and sense of belonging to an organization.

Organizing The process of coordinating the work to be done. Formally, it involves identifying the work of the organization, dividing the labor, developing the chain of command, and assigning authority.

Orgasmic phase The phase of the sexual response cycle that is marked by the involuntary release of sexual tension accompanied by physiologic and psychologic release.

Orientation 1. A structured program of activities to help new employees adapt to their new workplace; it is geared toward helping newly employed nurses to be successful. 2. A newborn's ability to be alert to, follow, and fixate on appealing and attractive, complex visual stimuli. 3. A component of normal perception that includes four basic elements: person, place, time, and situation.

Orthopnea Difficulty breathing when supine.

Orthopneic position A body position with the head and arms supported on the overbed table to facilitate breathing.

Orthotic devices Orthopedic devices that may include splints or braces applied to reduce strain on a joint.

Ortolani maneuver A procedure used to evaluate an infant for developmental dysplastic hip.

Osmolality A measure of the concentration of solutes in body fluids. Osmolality is determined by the total solute concentration within a fluid compartment and is measured as parts of solute per kilogram of water.

Osmolar imbalance A fluid imbalance that involves the loss or gain of only water, so that the osmolality of the serum is altered.

Osmosis The movement of water across cell membranes, from a less concentrated solution to a more concentrated solution.

Osmotic pressure The power of a solution to draw water across a semipermeable membrane.

Ossification The development of bone.

Osteoarthritis (OA) The most common form of arthritis in older adults. It is caused by chronic degenerative changes in the cartilage and synovial membranes of the joints.

Osteoblasts Cells that form bone.

Osteoclasts Cells that resorb bone.

Osteocytes Cells that maintain bone matrix.

Osteodystrophy A complex bone disease process of chronic kidney disease in which chronic hyperparathyroidism causes increased resorption of bone.

Osteomyelitis Infection of the bone in a compound fracture.

Osteophytes Bony spurs that form as cartilage deteriorates.

Osteoporosis A metabolic bone disorder characterized by loss of bone mass, increased bone fragility, and increased risk of fractures.

Osteotomy 1. Surgical removal of a wedge of bones above or below a joint to realign the joint and shift weight away from the damaged portion of a joint. 2. An incision into or transection of the bone.

Otitis externa Inflammation of the ear canal. It is often called *swimmer's ear* because it is most frequently found in people who spend significant time in the water.

Otitis interna An inflammation of the inner ear. Also called *labyrinthitis*.

Otitis media Inflammation of the middle ear.

Otoscope A handheld instrument with a light and a cone-shaped attachment; known as an *ear speculum*.

Outcome The specific, observable criteria used to evaluate whether goals have been met and the effectiveness of nursing actions.

Outcome standards Standards that focus on the performance of a process, such as the number of bedridden patients who develop a pressure injury.

Outcomes management Management process that uses patient experiences to guide improvement in all areas of healthcare by providing a link between medical interventions and health outcomes and between health outcomes and the cost of care.

Output Energy, material, or information that a system gives out as a result of its processes.

Ovarian cycle The three cyclical phases of oogenesis that occur about every 28 days.

Ovarian ligaments Ligaments that anchor the lower pole of the ovary to the uterus.

Ovaries Female sex glands in which the ova are formed and in which estrogen and progesterone are produced. Normally, a woman has two ovaries.

Overdelegation A situation that occurs when a delegator loses control over a situation by providing a delegate with too much authority or too much responsibility. This places the delegator in a risky position, increasing the potential for liability.

Overnutrition Health effects caused by excessive or accelerated nutrient intake or stores, such as obesity, hypertension, hypercholesterolemia, or toxic levels of stored vitamins or minerals.

Overt conflict Conflict that is addressed openly and is generally obvious to the individuals involved.

Ovulation Normal process of discharging a mature ovum from an ovary approximately 14 days before the onset of menses.

Oxygenation The mechanism that facilitates or impairs the body's ability to supply oxygen to all cells of the body.

Pacemaker An external or implanted pulse generator used to provide an electrical stimulus to the heart when the heart fails to generate or conduct its own stimulus at a rate that maintains the cardiac output.

PaCO₂ A measure of the pressure exerted by dissolved carbon dioxide in the blood; it reflects the respiratory component of acid-base regulation and balance because it is regulated by the lungs.

Pain An unpleasant sensory and emotional experience associated with actual or potential tissue damage.

Pain threshold The point at which pain is initially perceived.

Pain tolerance The duration of time or intensity of pain an individual will endure before demonstrating pain responses.

Palliation Measures taken not to cure a disease, but to relieve disease-related symptoms and enhance the patient's quality of life. See also Palliative care.

Palliative care Nursing care that improves the quality of life of patients and their families facing life-threatening illness by preventing, assessing, and treating pain and other physical, psychosocial, and spiritual problems.

Palliative procedure A surgical or interventional cardiac catheterization procedure that does not create normal anatomic or hemodynamic results but allows adequate blood flow to oxygenate the tissues.

Pallidotomy A surgical technique for Parkinson disease in which the neurosurgeon locates the affected areas of the globus pallidus and destroys the involved tissue in order to improve tremors and mobility.

Palpation A method of assessment that involves touching the areas related to the body system to determine symmetry, equality of the size, shape, or condition of opposite sides of the body.

Pancreatitis Inflammation of the pancreas that occurs when pancreatic enzymes are released into the pancreas itself, causing autodigestion of pancreatic tissues.

Pandemic Widespread global outbreak of an infectious disease.

Panic disorder A sudden attack of terror, sometimes accompanied by a pounding heart, sweating, fainting, or dizziness.

Pannus An abnormal tissue layer that includes newly formed blood vessels. Pannus leads to scar tissue formation that immobilizes joints.

PaO₂ A measure of the pressure exerted by oxygen that is dissolved in the plasma.

Para Term used to describe a woman who has borne offspring who reached the age of viability.

Paracentesis Aspiration of fluid from the peritoneal cavity.

Parallel play A stage of play in which toddlers play side by side with similar objects, but do not play together.

Paranoia An extreme suspicion that others are "out to get you" and delusions that one is being followed and that others are trying to harm oneself; experienced by some individuals with psychosis.

Paranoid personality disorder (PPD) One of several personality disorders defined in the DSM-5, it is characterized by the inability to trust others, hypervigilance, pathologic jealousy, and prejudicial and judgmental tendencies.

Paraplegia Paralysis of all or part of the lower portion of the body.

Paraphimosis Condition in which the retracted foreskin becomes trapped over the glans and tightens on the penis, causing painful swelling.

Parasite One of the four categories of microorganisms, parasites live on other organisms.

Parasomnias Abnormal behaviors that may interfere with sleep and may occur during sleep.

Parenteral nutrition (PN) The intravenous administration of amino acids, often with added carbohydrates, fats, electrolytes, vitamins, and minerals.

Parenting The ongoing act of guiding children to learn acceptable behaviors, morals, and rituals of the family and of teaching them to become socially responsible, contributing members of society.

Paresis Weakness.

Paresthesia Sensation of prickling, tingling, or numbing.

Parkinson disease (PD) A degenerative disorder of the central nervous system resulting from the death of neurons that produce the brain neurotransmitter dopamine.

Parkinsonian gait Altered gait characterized by small, shuffling steps, as well as bradykinesia or festination.

Parkinsonism The motor symptoms of Parkinson disease: tremors, muscle rigidity, postural instability, and bradykinesia.

Paroxysmal Occurring in bursts with an abrupt onset and termination.

Paroxysmal nocturnal dyspnea A sudden episode of shortness of breath occurring at night during sleep.

Partial-thickness burns Burns that involve the entire dermis and the papillae of the dermis (superficial partial-thickness burns) or extend into the hair follicles (deep partial-thickness burns).

Passive acquired immunity A condition that occurs when a pregnant woman passes IgG antibodies to a fetus in utero.

Passive behavior Behavior that seeks to avoid conflict at any cost, even at the expense of one's own happiness.

Passive communicators Individuals who focus on the needs of others. They often deny themselves any sort of power, which causes them to become frustrated.

Passive immunity Temporary protection—provided by antibodies produced by other people or animals—against disease-producing antigens. Protection is gradually lost when these acquired antibodies are used up either by natural degradation or by combining with the antigen.

Patch testing A test used to identify allergens causing dermatitis. An adhesive patch with common allergens is placed on the back between the scapulae. The patch is generally removed after several days; if there is no reaction to a particular allergen, that allergen is eliminated as a possible cause of dermatitis.

Patent airway An airway that is open and free of obstruction.

Patent ductus arteriosus (PDA) A congenital connection between the great vessels that normally closes after birth, allowing blood from the right and left side of the heart to mix.

Pathogen A microorganism that causes disease.

Pathogenicity The ability to produce disease.

Pathologic fracture A fracture that results from disease that has weakened the bone.

Patient An individual who is waiting for or undergoing medical treatment and care.

Patient advocacy Process or strategy for acting on behalf of others, including patients, families, groups, or communities, to help them obtain services and rights that they might not otherwise receive but that they need to advance their well-being.

Patient-centered medical home A model of care in which a patient's primary care provider works with the patient and family to develop a personalized plan that addresses the patient's physical and mental health needs across the lifespan.

Patient-controlled analgesia (PCA) A pump with a control mechanism that allows the patient to self-manage pain.

Patient-focused care A delivery model that organizes healthcare around the expressed physical and emotional needs of the patient.

Patient Protection and Affordable Care Act (PPACA or ACA) A law enacted during the presidency of Barak Obama designed to increase access to and affordability of healthcare. Also called *Obamacare*.

Patient record A formal, legal document that provides evidence of a patient's care. Also called a *chart* or a *clinical record*.

Patient Self-Determination Act (PSDA) A federal law that requires every competent adult to be informed in writing on admission to a healthcare institution about his or her rights to accept or refuse medical care and to use advance directives.

Pauciarticular arthritis A form of juvenile rheumatoid arthritis that primarily affects the knees, ankles, and elbows; it occurs more frequently in females.

Peak expiratory flow rate (PEFR) A measurement used to monitor the ability of an individual to exhale a specific volume of air related to the individual's age, gender, height, and weight.

Pedagogy The study or science of teaching, specifically referring to children and adolescents.

Pedigree The graphic representation of a family tree, usually to trace genetic abnormalities.

Peer review A method to professionally critique a colleague's work based on predetermined standards.

Pelvic cavity Bony portion of the birth passage; a curved canal with a longer posterior than anterior wall.

Pelvic diaphragm Part of the pelvic floor, composed of deep fascia and the levator ani and the coccygeal muscles.

Pelvic floor exercises Isometric exercises to strengthen the pelvic floor muscles for increased support of the neighboring organs.

Pelvic inlet Upper border of the true pelvis.

Pelvic outlet Lower border of the true pelvis.

Pelvic tilt An exercise that helps prevent or reduce back strain as it strengthens abdominal muscles. Also called *pelvic rocking*.

Penetrating injury Also called an open injury, a penetrating injury causes an open wound with focal damage around the site of the injury. When referring to eye injuries specifically, in a penetrating injury, the layers of the eye spontaneously reapproximate after entry of a sharp-pointed object or small missile (e.g., a BB) into the globe.

Penetrating trauma Trauma that occurs when a foreign object enters the body, causing damage to body structures.

Penta screen Maternal screening that measures five indicators whose presence may suggest fetal complications: AFP, beta hCG, unconjugated estriol, inhibin A, and invasive trophoblast antigen.

Penumbra A band of minimally perfused cells that surrounds a central core of dead or dying cells.

Peplau, Hildegard A nursing theorist who is widely considered the mother of psychiatric nursing; she presented nursing as a therapeutic interpersonal process, rather than as a task-oriented process.

Peptic ulcer A break in the mucosal lining of the GI tract exposed to acid-pepsin secretions, including the esophagus, stomach, and duodenum.

Peptic ulcer disease (PUD) A break in the mucous lining of the GI tract where it comes in contact with gastric juice.

Perceived loss A loss that is experienced by one person but cannot be verified by others.

Perception Awareness and interpretation of stimuli; the ability of the individual to interpret the environment.

Percussion A method of tapping the chest or back to assess underlying structures. More forceful striking of the skin with cupped hands is sometimes called *clapping*.

Percutaneous coronary revascularization (PCR) Procedures are used to restore blood flow to the ischemic myocardium in patients with CAD.

Percutaneous transluminal coronary angioplasty (PTCA) A type of PCR (see above entry) in which a balloon-tipped catheter is threaded over the guidewire, with the balloon positioned across the area of narrowing.

Perforating injury A type of eye injury in which the layers of the eye do not spontaneously reapproximate after the entry of a sharp-pointed object or small missile (e.g., a BB) into the globe, which results in rupture of the globe and potential loss of ocular contents.

Perforation Rupture, as in the penetration of ulcer through mucosal wall.

Performance improvement Quality of care improvement is directly linked to the performance of an individual, team, unit, or organization.

Pericarditis Inflammation of the pericardial tissue surrounding the heart.

Pericardium A double layer of fibroserous membrane that encases and anchors the heart.

Perimenopause A period of hormonal change during which the body gradually transitions toward permanent infertility.

Perimetrium The outermost layer of the uterus.

Perinatal loss Death of a fetus or infant that occurs between the time of conception and the end of the newborn period 28 days after birth.

Perineal body The wedge-shaped mass of fibromuscular tissue between the lower part of the vagina and the anus.

Periodic breathing A breathing pattern characterized by pauses lasting 5–15 seconds.

Periodontal disease Gum disease.

Perioperative The three phases of a surgical procedure: the preoperative phase, intraoperative phase, and postoperative phase.

Perioperative nursing care Nursing care provided during any or all of the three phases of surgery: preoperative, intraoperative, and postoperative.

Peripartum cardiomyopathy A rare but serious dysfunction of the left ventricle that occurs in the last month of pregnancy or the first 5 months postpartum in a woman with no previous history of heart disease.

Peripheral nervous system (PNS) One of two principal parts of the neurologic system, the peripheral nervous system consists of the cranial nerves and the spinal nerves.

Peripheral neuropathy A condition that results when trauma or a disease process interferes with innervation of peripheral nerves.

Peripheral pulse A pulse located away from the heart, in the foot or the wrist.

Peripheral vascular disease (PVD) A disorder in which arteriosclerosis and atherosclerosis affect circulation to peripheral tissues, particularly the lower extremities.

Peripheral vascular resistance The opposing forces or impedance to blood flow as the arterial channels become more and more distant from the heart.

Peristalsis The process of wavelike muscular contractions that propels food and digestive products through the digestive tract.

Peritoneal dialysis The process by which dialysate is instilled into the abdominal cavity through a catheter, allowed to rest there while fluids and molecules exchange, and then removed through the catheter.

Peritonitis Inflammation and bacterial infection of the abdominal area.

Pernicious anemia A disorder that results from a failure to absorb dietary vitamin B₁₂.

Perseveration Use of the same words or phrases repetitively.

Persistent A term used to describe a disease or disorder (such as rheumatoid arthritis) that lasts for a period of 3–6 months or longer.

Persistent bacteriuria The reappearance of bacteria in urine due to a persistent source of infection causing repeated infection after the initial cure.

Persistent depressive disorder Chronic depression that affects an individual for the majority of most days for at least 2 years (1 year for children and adolescents). May be interrupted by periods of normal mood that do not exceed 2 months over the course of the 2 years. Also called *dysthymic disorder*.

Persistent vegetative state A permanent condition of complete unawareness of self and the environment and loss of all cognitive functions. Also called *irreversible coma*.

Personal distance Communication characterized by moderate voice tones, less noticeable body heat and smell. Physical contact such as a handshake or touching a shoulder is possible.

Personal identity The conscious sense of individuality and uniqueness that is continually evolving throughout life.

Personal knowing A nurse's commitment to ongoing, individual self-exploration and self-actualization.

Personal space The distance people prefer in interactions with others.

Personality The individual qualities, including habitual behavior patterns, that make an individual unique; the outward expression of the inner self.

Personality disorder (PD) Rigid, stereotyped behavioral patterns that deviate markedly from the norm of an individual's culture and persist throughout the person's life. Personality disorders are characterized by a lifelong maladaptive pattern of perceiving, thinking, and relating that impairs social or occupational functioning.

Personality traits The elements and patterns that make up an individual's personality.

Pessimism A feeling that a situation is always bad and may become worse.

pH A measurement of the hydrogen ion concentration of a solution.

Phagocytosis A process by which a foreign agent or target cell is engulfed, destroyed, and digested. Neutrophils and macrophages, known as phagocytes, are the primary cells involved in phagocytosis.

Phantom pain A confusing pain syndrome that occurs following surgical or traumatic amputation of a limb. The patient experiences pain in the missing body part even though there is complete mental awareness that the limb is gone. Also called *phantom limb syndrome*.

Phase of mutual regulation Time period during which a mother and her infant seek to determine the degree of control each partner in their

relationship will exert. In this phase of adjustment, a balance is sought between the needs of the mother and the needs of the infant.

Phenotype The observable expression of genetic traits.

Philadelphia chromosome The balanced translocation of chromosome 22 to chromosome 9; associated with chronic myeloid leukemia.

Phimosis Tightness of the prepuce that prevents retraction of the foreskin.

Phobia An intense, persistent, irrational fear of a simple thing or social situation that compels the individual to avoid the stressor that elicits the fear.

Photophobia Sensitivity to light.

Physical activity Body movement produced by skeletal muscle contraction that increases energy expenditure.

Physical fitness The ability to carry out tasks with vigor and alertness and without fatigue, while still maintaining enough energy for other tasks.

Physical attending The conveyed act of being with another individual through physical posturing.

Physical restraint Any manual method, material, device, or equipment that is attached to the patient's body with the intention of limiting or restricting free movement of the patient's head, arms, legs, or body.

Physiologic anemia of infancy A type of anemia that occurs as a result of the normal, gradual drop in hemoglobin for the first 6–12 weeks of life.

Physiologic anemia of pregnancy Apparent anemia that results because during pregnancy the plasma volume increases more than the erythrocytes increase. Also called *pseudoanemia*.

Physiologic jaundice A yellow discoloration of the skin caused by accelerated destruction of fetal red blood cells, impaired conjugation of bilirubin, and increased bilirubin reabsorption from the intestinal tract.

Physiologic pain Experienced when an intact, properly functioning nervous system sends signals that tissues are damaged, requiring attention and proper care.

Physiologic tremors Tremors that occur normally as a result of physiologic exhaustion or emotional stress.

Pica The craving for and persistent eating of nonnutritive substances not ordinarily considered to be edible or nutritionally valuable, such as soil, clay, and soap.

PICOT A mnemonic method used by clinicians to define and formulate a clinical question driving the search for evidence-based practice. PICOT stands for Population of a group, Intervention or activity focus, Comparison group, Outcome(s) or desired effects, and Time frame.

Pigmented basal cell carcinoma A type of skin cancer.

Pill-rolling Rubbing of the thumb and fingers together accompanying other tremors.

Piloerection Goosebumps.

Pilot projects Limited trials to determine problems with problem-solving alternatives. Pilot project strategies may resemble research projects and may be linked to quality improvement initiatives.

Pitch The frequency of vibrations in a sound.

Pitfall A hidden trap that catches people unaware and undermines their plans.

Pitting edema Edema that retains indentation caused by pressure.

Placenta A flat, disc-shaped organ that is highly vascular and normally forms in the upper segment of the endometrium of the uterus; exchanges nutrients and gases between the fetus and the mother.

Placenta previa Occurs when the placenta partially or totally covers the mother's cervix; can result in severe bleeding before or during delivery.

Placental abruption A condition that occurs when the placenta detaches from the uterine wall before delivery. May or may not result

in fetal demise, but a fetus's survival depends on the stage of development and prompt medical treatment.

Plan-do-study-act (PDSA) A system of quality improvement most often associated with total quality management.

Planning The four-stage managerial process that establishes objectives, evaluates the present situation in order to predict future trends and events, formulates a planning statement, and converts the plan into an action statement.

Plaque 1. An invisible soft film that adheres to the enamel surface of teeth. Consists of bacteria, saliva molecules, and remnants of epithelial cells and leukocytes. 2. Scar tissue on myelin sheath due to repeated attacks by the immune system.

Plateau phase A phase of the **sexual response cycle** during which individuals experience strong, prolonged sexual arousal. The plateau phase is typically maintained by physical stimulation.

Plasmapheresis Removal of a harmful component from plasma. Also called *plasma exchange therapy*.

Play therapist A therapist who designs and provides recreational activities to promote emotional and/or physical healing and wellness.

Pleural effusion Accumulation of excess fluid in the pleural cavity.

Pleural friction rub Associated with pleural inflammation, it occurs when inflamed pleural surfaces slide across one another. This low-pitched, crackling sound typically is present during both inspiration and expiration.

Pleural space The region between the visceral and parietal pleura.

Pleuritic pain Sharp localized chest pain that increases with breathing and coughing.

Pleuritis Local extension of an infection to involve the pleura.

Pleximeter The middle finger of the nondominant hand. Often used in indirect percussion techniques.

Plexor The middle finger of the dominant hand. Often used in indirect percussion techniques.

Pneumatic retinopexy A surgical procedure to correct retinal detachment in which air is injected into the vitreous cavity and the patient is positioned so that the air bubble pushes the detached portion of the retina into contact with the choroid.

Pneumocystis jirovecii **pneumonia** An opportunistic infection that is not pathogenic in those with intact immune systems.

Pneumomediastinum The presence of air in the mediastinum.

Pneumonia Inflammation of the lung parenchyma (the respiratory bronchioles and alveoli).

Pneumopericardium Air in the pericardial sac.

Pneumothorax A partial lung collapse due to air or gas collecting in the lung or in the pleural space that surrounds the lungs.

Point of care Interventions or testing that provides on-the-spot information about the patient rather than having to send blood or urine samples down to the laboratory and wait for results to be returned.

Point of maximal impulse (PMI) A pulse located at the apex of the heart. Also called the *apical pulse*.

Point-of-service (POS) plan An insurance plan that allows the insured to choose between a health maintenance organization or a preferred provider organization each time they seek healthcare.

Polyarticular arthritis A form of juvenile rheumatoid arthritis that involves many joints (five or more), particularly the small joints of the hands and fingers. It may also affect the hips, knees, feet, ankles, and neck.

Polycyclic Describes a periodically recurring course of rheumatoid arthritis.

Polycythemia An increase in the production of red blood cells.

Polydipsia Excessive thirst.

Polyneuropathies Bilateral sensory disorders; they are the most common types of neuropathy associated with diabetes.

Polyp A small vascular growth on the surface of any mucous membrane.

Polyphagia Excessive hunger.

Polysomnography (PSG) A recording of the biophysical changes that a patient experiences during sleep.

Polysubstance abuse The simultaneous use of many substances.

Polyuria The production of abnormally large amounts of urine. Also called *diuresis*.

Pop-ups Unexpected things or events occurring during the day that require time and attention in addition to the regular plan for the day.

Positive end-expiratory pressure (PEEP) Mechanical ventilation in which a positive pressure is maintained in the airways during exhalation and between breaths to help keep alveoli open.

Positive feedback Output of a system that returns to the system as input and which promotes system change.

Positive pressure ventilator A mechanical device that pushes air into the lungs through an invasive device such as an endotracheal tube or tracheostomy tube, rather than drawing air in by negative pressure.

Positive punishment The addition of a negative consequence if undesirable behavior occurs.

Positive reinforcement Giving rewards such as praise or encouragement for a learner's achievements.

Positive symptoms Excessive or added behaviors that are not normally seen in healthy adults, such as delusions; commonly seen in schizophrenia.

Postanesthesia care unit (PACU) Designated unit for postoperative recovery of patients who do not require intensive care following a surgical procedure with anesthesia.

Postcoital contraception A drug taken after intercourse to avoid pregnancy. Also called *Plan B* or the *morning after pill*.

Postconception age periods Period of time in embryonic/fetal development calculated from the time of fertilization of the ovum.

Postconcussion syndrome A series of concussion-like symptoms that occur 7–10 days after a concussion. Manifestations include nausea, headache, dizziness, fatigue, memory problems, difficulty concentrating, insomnia, light and noise sensitivity, and/or personality changes.

Postictal period A period immediately following seizure activity in which level of consciousness is decreased. The length of the postictal period varies.

Postmenopausal bleeding Bleeding that occurs after menopause has occurred; may be caused by endometrial polyps, endometrial hyperplasia, or uterine cancer.

Postoperative The third phase of an operative process in which recovery occurs.

Postpartal hemorrhage A loss of blood of greater than 500 mL following birth. The hemorrhage is classified as *early* if it occurs within the first 24 hours and *late* if it occurs after the first 24 hours.

Postpartum After childbirth.

Postpartum blues A maternal adjustment reaction occurring in the first few postpartum days, characterized by mild depression, tearfulness, anxiety, headache, and irritability. Also called *adjustment reaction to depressed mood*.

Postpartum depression A severe form of depression that affects new mothers, often beginning within 3 months of delivery but which may strike at any time during the first year after having a child. Also called *depressive disorder with peripartum onset*.

Postpartum endometritis (metritis) An inflammation of the endometrium portion of the uterine lining occurring anytime up to 6 weeks postpartum.

Postpartum psychosis Severe psychosis occurring within the first 3 months after birth that usually requires hospitalization.

Postterm labor Labor that occurs after 42 weeks' gestation.

Postterm newborn Any infant born after 42 weeks' gestation.

Postterm pregnancy Pregnancy that lasts beyond 42 weeks' gestation.

Posttraumatic stress disorder (PTSD) A trauma- and stressor-related disorder that can evolve after exposure to a traumatic or overwhelming event in which an individual's physical health was endangered.

Postural drainage The drainage by gravity of secretions from various lung segments.

PPD Tuberculin skin test. See Purified protein derivative.

Prader-Willi syndrome (PWS) A congenital disorder of the 15th chromosome that causes an unrelenting feeling of hunger, but also low muscle tone, short stature, incomplete sexual development, mild to severe mental retardation, and behavioral problems.

Prayer Human communication with divine and spiritual entities.

Preceptor An experienced nurse who provides knowledge and emotional support, as well as a clarification of role expectations, on a one-to-one basis.

Precipitating factor A practice, behavior, or environmental factor that gives rise to a specific incident of violence.

Predisposing factor A practice, behavior, or environmental factor that increases the potential of an individual's risk of violent victimization or perpetration of violence.

Preeclampsia An increase in blood pressure after 20 weeks of gestation accompanied by proteinuria. May also be accompanied by albuminuria and edema. Also called *toxemia of pregnancy*.

Preferred provider organization (PPO) A type of health insurance program that does not require its insureds to select a primary care provider. PPOs usually have larger networks of providers than health maintenance organizations (HMOs) and provide financial incentives that encourage insureds to seek care from in-network providers. They are less restrictive than HMOs but typically have higher copayments.

Prejudice A negative belief or preference that is generalized about a group that leads to prejudgment.

Preload The amount of cardiac muscle fiber tension, or stretch, that exists at the end of diastole.

Premature ejaculation Ejaculation that occurs consistently before or shortly after penetration; i.e., before both partners are able to achieve satisfaction.

Premature junctional contractions Heartbeats that occur before the next expected beat of the underlying rhythm.

Premature rupture of membranes (PROM) Spontaneous rupture of membranes and leakage of amniotic fluid before the onset of labor at any gestational age.

Premenstrual syndrome (PMS) A complex of manifestations (e.g., mood swings, breast tenderness, fatigue, irritability, food cravings, and depression) that occurs 3–14 days before menstruation and is relieved by the onset of menses.

Prenatal education Programs offered to expectant families, adolescents, women, or partners to provide education regarding the pregnancy, labor, and birth experience.

Preoperative The first phase of an operative process in which the patient is identified as a candidate for surgical intervention, assessed, and prepared for surgery.

Preorgasmic Never having had an orgasm.

Preparedness The phase that takes place before an emergency occurs during which risks are assessed and plans are developed to address them.

Preprocedure verification process A standardized process used to verify that the correct procedure is being implemented on the correct patient at the correct site, and that all items necessary for the procedure are available.

Presbycusis Age-related loss of the ability to hear high-frequency sounds; may occur because of cochlear hair cell degeneration or loss of auditory neurons in the organ of Corti.

Presbyopia Impaired near vision resulting from a loss of elasticity of the lens related to aging.

Presencing Being present with a patient and being open, receptive, and available at all levels without judging or labeling.

Presenting part The first part of the fetus to enter and settle in the pelvic inlet during fetal presentation.

Pressure injury Ischemic lesions of the skin and underlying tissue caused by external pressure that impairs the flow of blood and lymph.

Preterm infant An infant born at less than 37 completed weeks of gestation.

Preterm premature rupture of the membranes (PPROM) A condition that occurs when membranes rupture and amniotic fluid leaks from the vagina before 37 weeks of gestation.

Pretibial myxedema The bilateral formation of edematous, erythematous, and sometimes hyperpigmented plaques and nodules over the shins and dorsal surface of the feet. A characteristic sign of Graves disease.

Priapism Persistent, painful erection of the penis.

Primary appraisal The evaluation of an event or circumstance in terms of its potential to harm, benefit, threaten, or challenge the individual.

Primary care provider (PCP) A healthcare provider who provides basic medical service and acts as a gatekeeper to more specialized care, referring patients to in-network hospitals and specialists.

Primary group A small, intimate group in which the relationships among members are personal, spontaneous, sentimental, cooperative, and inclusive.

Primary hypertension A persistently elevated systemic blood pressure. Also called *essential hypertension*.

Primary immune response When an individual is exposed to an antigen, the B-lymphocyte system produces antibodies that react specifically with that antigen over the first 3 days.

Primary intention healing Healing that occurs where the tissue surfaces have been closed and there is minimal or no tissue loss. It is characterized by the formation of minimal granulation tissue and scarring. Also called *primary union* or *first intention healing*.

Primary nursing A model in which one nurse has 24/7 authority and responsibility for the care of an assigned group of patients.

Primary prevention Methods designed to focus on health promotion and illness prevention.

Primary sex characteristics The reproductive organs.

Primigravida A woman who is pregnant for the first time.

Primipara Term used to describe a woman who has given birth to her first child (past the point of viability), whether or not that child is living or was alive at birth.

Principles-based (deontologic) theories Theories that involve logical and formal processes and emphasize individual rights, duties, and obligations.

Prioritizing care A process that helps nurses manage time and establish an order for completing responsibilities and care interventions for a single patient or for a group of patients.

Priority Something given or meriting attention before competing alternatives.

Privacy The right of individuals to keep their personal information from being disclosed.

Private insurance Health insurance provided by private or publicly owned companies such as Blue Cross Blue Shield, Kaiser, or Aetna.

Probiotics Microorganisms that aid in digestion and help to protect the body from harmful bacteria.

Problem-focused coping Managing or altering a stressor, event, or circumstance in response to distress.

Problem, intervention, evaluation (PIE) An assessment system consisting of patient care flow sheets and progress notes.

Problem-oriented medical record (POMR) A recording system in which data are arranged according to the problems the patient has rather than the source of the information. Also called *problem-oriented record (POR)*.

Problem-oriented record (POR) See Problem-oriented medical record (POMR).

Procedural memory Recall of information that does not require conscious awareness and involves the memory of motor skills and procedures.

Process addictions Compulsive behaviors that serve to reduce anxiety such as workaholism, gambling, shopping, cutting, pornography, spending and indebtedness, internet surfing or gaming, eating disorders, and sexual addictions.

Process standards Standards that focus on the steps used to lead to a particular outcome. It is used to determine if a set of steps exists and if those steps are being followed.

Productivity The performance measure of both the effectiveness and efficiency of nursing care.

Profession An occupation that requires extensive education or a calling that requires special knowledge, skill, and preparation.

Professional behaviors Effective nursing actions based on ethical principles, clinical reasoning, and technical knowledge and expertise that form helping relationships.

Professional development Continued staff education, planned activities to enhance role performance, and defined goals to improve patient outcomes. Also called *staff development*.

Professional support Assistance provided by professionals in the community who exhibit a nonblaming and respectful attitude toward families and patients and who provide information and help locating community resources.

Professionalism Acting with the knowledge, skill, and preparation of a professional.

Professionalization The process of establishing qualifications, ethical guidelines, and a standardized knowledge base by which an occupation transforms itself into a profession.

Progesterone Hormone produced by the corpus luteum, adrenal cortex, and placenta whose function is to stimulate proliferation of the endometrium to facilitate growth of the embryo.

Projectile vomiting Vomiting in which emesis may be spewed up to 2–3 feet out of a baby's mouth. A major symptom of pyloric stenosis.

Prone Face-down.

Proprioception The body's sense of its position.

Proptosis Forward displacement of the eye.

Prospective payment system (PPS) A system in which hospitals determine the amount to be billed to the insurance company before the patient is ever admitted to the hospital.

Prostaglandins (PGs) Complex lipid compounds synthesized by many cells of the body.

Prostate specific antigen (PSA) A protein produced in the cells of the prostate gland.

Prostatectomy Surgical removal of part or all of the prostate gland.

Prostatitis An inflammation of the prostate gland.

Prostatodynia A condition in which the patient experiences the symptoms of prostatitis, but shows no evidence of inflammation or infection.

Protected health information Personal information or healthcare data that could identify an individual. This information is protected and defined by HIPAA's Privacy Rule.

Protective factor 1. A practice, behavior, or environmental factor that provides strength and assistance to children and families in dealing with crises and risk factors. 2. A practice, behavior, or environmental factor that decreases the potential of an individual to perpetuate violence or victimization.

Protein A macronutrient that contains nitrogen and is a critical component of all tissues in the human body, including muscle, bone, and blood.

Protein-calorie malnutrition Problem of patients with long-term deficiencies in caloric intake; characteristics include depressed visceral proteins (e.g., albumin), weight loss, and visible muscle and fat wasting.

Proteinuria Excess protein in urine.

Proxemics The study of distance between people in their interactions.

Proximodistal Growth that proceeds from the center of the body outward.

Proximodistal development Development that proceeds from the center of the body outward.

Pruritus Itching of the skin.

Pseudoaddiction A term applied to patients who display drug-seeking behaviors but differ from addicts in that they have true underlying pain for which they are seeking relief. These behaviors will generally stop when adequate pain control is achieved.

Pseudoexacerbation A temporary aggravation of symptoms that is directly related to a trigger and subsides as soon as the trigger is removed.

Pseudomenstruation Blood or whitish discharge may occasionally be observed on the diapers of female newborns caused by the withdrawal of maternal hormones.

Purified protein derivative (PPD) Used to screen for tuberculosis in a tuberculin test. A small amount of the PPD is injected and the body's response interpreted.

Purulent exudate A large quantity of cells and necrotic debris that form an opaque or milky discharge that is thicker than serous exudate. Also called *pus* or *suppuration*.

Pus The common name for *purulent exudate*.

Psychoanalytic theory A framework for personality development that emphasizes the presence of unconscious impulses and their influence on behaviors and the formation of self; developed by Sigmund Freud (1856–1939).

Psychogenic pain Pain that is experienced in the absence of any diagnosed physiologic cause or event.

Psychomotor domain The learning domain that includes fine motor skills. Also called the *skill domain*.

Psychomotor retardation A state in which thinking and body movements are noticeably slower than normal and speech is slowed or absent.

Psychosis A mental health condition characterized by delusions, hallucinations, illusions, disorganized behavior, and a difficulty relating to others. Also called *psychotic disorder*.

Psychosocial skills Skills that enable an individual in crisis to maintain relationships with family and friends throughout and after the crisis period.

Psychostimulants Stimulants that have a high potential for abuse. Psychostimulants include cocaine and amphetamines.

Psychoticism One of the six trait domains associated with personality disorders that is composed of eccentricity, cognitive and perceptual dysregulation, and unusual beliefs and experiences.

Ptoxis Drooping of the eyelid.

Ptyalism Excessive, often bitter salivation.

Puberty The stage during which an individual reaches sexual maturity.

Pubis Pertaining to the pubes or pubic area.

Public distance Communication that requires loud, clear vocalizations with careful enunciation.

Public insurance Health insurance financed by the government.

Public self How the individual wishes to be perceived by others.

Puerperium That time immediately following childbirth during which physiologic changes that occurred during pregnancy begin to return to normal. Also called *postpartum period*.

Pulmonary atresia The absence of communication between the right ventricle and the pulmonary artery.

Pulmonary circulation Circulation through the right side of the heart, the pulmonary artery, the pulmonary capillaries, and the pulmonary vein.

Pulmonary edema An abnormal accumulation of fluid in the interstitial tissue and alveoli of the lung.

Pulmonary embolism (PE) The obstruction of blood flow in part of the pulmonary vascular system by an embolus. Also called *pulmonary thromboembolism*.

Pulmonary function test (PFT) A test designed to provide information about ventilation airflow, lung volume, and the capacity and diffusion of gas.

Pulmonary vascular resistance The force or resistance of the blood in the pulmonary circulation.

Pulse A wave of blood created by the contraction of the left ventricle of the heart.

Pulse oximetry A noninvasive method of assessing arterial blood oxygenation.

Pulse pressure The difference between the systolic and diastolic pressure.

Pulse rhythm The pattern of the beats and the intervals between the beats.

Punctual On time.

Punishment 1. Action taken to enforce rules when a child misbehaves. 2. Consequences that lead to a decrease in undesirable behavior.

Pupillary light reflex Reflex in which the pupil contracts in response to a bright light.

Purging Self-induced vomiting or misuse of laxatives, diuretics, or enemas.

Pursed-lipped breathing Exhaling through a narrow opening between the lips to prolong the expiratory phase in an effort to promote more alveolar emptying while maintaining open alveoli.

Pyelolithotomy An incision into and removal of a stone from the kidney pelvis.

Pyelonephritis Inflammation of the renal pelvis and parenchyma, the functional kidney tissue.

Pyloric stenosis A thickening of the pyloric muscle resulting in a narrowing of the pyloric sphincter between the stomach and small intestine.

Pyogenic bacteria Bacteria that produces purulent exudate or pus.

Pyorrhea Advanced periodontal disease.

Pyuria Cloudy or pus-filled urine.

Quadriplegia Complete loss of function of the upper and lower body, including the arms, trunk, legs, and pelvic organs. Also called *tetraplegia*.

Quadruple screen The most widely used test to screen for Down syndrome (trisomy 21), trisomy 18, and neural tube defects.

Qualifiers Words that have been added to some NANDA nursing diagnosis labels to give additional meaning to the diagnostic statement.

Qualitative research Investigates a question through narrative data from interviews, storytelling, and description of observation to provide a better understanding of the patient's perspective.

Quality 1. A subjective description of a sound, for example: whistling, gurgling, or snapping. 2. The degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge.

Quality and Safety Education for Nurses (QSEN) A program designed to identify and standardize the six core competencies or nursing: patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics.

Quality assurance The process of collecting data related to a problem and then analyzing the data based on benchmark standards to determine if standards are being met.

Quality improvement The process of using systematic and continuous actions that lead to measurable improvement in healthcare services and the health status of targeted patient groups.

Quality management The evaluation of medical and nursing processes for quality and effectiveness compared to accepted standards in order to correct problems before they harm patients and to prevent errors in treatment.

Quantitative research Uses precise measurements for data collection and employs statistical analysis to provide specific and objective data about a topic.

Quickening The mother's perception of fetal movement.

Race A term used to describe socially defined populations that share genetically transmitted physical characteristics, such as skin color and bone structure.

Racism The oppression of a group of people based on their perceived race.

Radiation The process of heat transfer with no physical contact.

Radiation cataracts A type of cataract that may result from long-term exposure to radiation.

Radical mastectomy The removal of an entire affected breast, its underlying chest muscles, and the lymph nodes under the arms. Compare with Simple mastectomy.

Range of motion (ROM) The degree to which a joint can be moved; a measurement of flexion and extension.

Range-of-motion (ROM) exercises Exercises designed to take each joint through all possible movements to maintain flexibility and movement in the joint.

Rape Any penetration, no matter how slight, of the vagina or anus with any body part or object, or oral penetration by a sex organ of another person, without the consent of the victim.

Rape-trauma syndrome (RTS) A series of psychologic sequelae that many victims experience following rape in addition to physiologic sequelae.

Rapport An understanding between two or more people.

Readiness to learn The demonstration of behaviors or cues that reflect a learner's motivation to learn at a specific time.

Real self The perceived true self.

Reappraisal An individual's ongoing evaluation and reinterpretation of an event or circumstance, as well as continued evaluation of the efficacy of the coping strategies.

Receiver This is the third component of the communication process. The receiver is the listener, who listens, observes, and attends.

Receptive speech The ability to understand the spoken word.

Receptor A nerve cell that converts a stimulus to a nerve impulse. Most receptors are specific, that is, sensitive to only one type of stimulus.

Record A formal, legal document that provides evidence of a patient's care. Also called a *patient record* or a *clinical chart*.

Recording The process of making an entry on a patient record. Also called *charting* or *documenting*.

Recovery 1. Return to (or exceed) preillness levels of functioning. 2. A continued state of voluntary sobriety in which an individual maintains personal health and functions normally. 3. A phase of mental illness in which symptoms of the disorder are present but under control.

Recurrence A later recurrence of a disorder after recovery.

Red blood cells (RBCs) Blood cells shaped like biconcave discs that contain the hemoglobin required for oxygen transport to body tissues; the most common type of blood cell. Also called *erythrocytes*.

Reduction Surgical placement of a broken bone in the correct alignment.

Referred pain Pain that is perceived in an area distant from the site of the stimuli.

Reflection The action of making sense of occurrences, situations, or decisions by carefully considering the totality of the experience: what worked or did not work, what could have been done differently to achieve better outcomes, what was done well, what necessary resources were available, and so on.

Reflexes The rapid, involuntary, predictable motor responses to a stimulus.

Reflux A backward flow of acidic secretions into the lower esophagus.

Refraction The bending of light rays as they pass from one medium to another medium of different optical density.

Refractory hypoxemia The decrease of particle arterial oxygen despite administration of oxygen at high flow rates.

Refractory period A phase during which myocardial cells resist stimulation.

Refractory septic shock A persistently low mean arterial blood pressure despite vasopressor therapy and adequate fluid resuscitation.

Regeneration The replacement or renewal of destroyed tissue cells by cells that are identical or similar in structure and function.

Registered nurses (RNs) The members of a nursing team who are specially licensed and trained to deliver direct patient care, including patient assessment, identification of health problems, and development and coordination of care.

Regurgitation The backflow of blood into the atria during systole.

Rehabilitation A level of wellness in which symptoms of the condition are under control to the extent that the affected individual can engage in goal-directed activities.

Reinfection The development of a new infection with a different pathogen following successful treatment.

Reinforcement Consequences that lead to an increase in a particular behavior.

Relapse Return of an acute phase of illness after recovery.

Relapsing fever Short febrile periods of a few days are interspersed with periods of 1–2 days of normal temperature.

Relationship-based (caring) theories Theories that stress courage, generosity, commitment, and the need to nurture and maintain relationships.

Relaxation response A healthful physiologic state that can be elicited through deep relaxation breathing with emphasis on a prolonged exhalation phase.

Religion A set of doctrines accepted by a group of people who gather together regularly to worship that offers a means to relate to God or a higher power; an organized system of beliefs and practices.

REM sleep Rapid-eye-movement sleep that occurs during sleep about every 90 minutes and lasts 5–30 minutes. The brain is highly active in this phase, and most dreams will take place during REM sleep.

Remission 1. A period during a chronic illness in which the symptoms of the illness disappear. 2. A sustained recovery lasting 8 weeks or more.

Remittent fever A wide range of fluctuating temperatures (more than 2°C [3.6°F]), all of which are above normal and occur over a 24-hour period.

Remyelination Repair of the damaged myelin sheath by oligodendrocytes.

Renal colic Acute, severe flank pain on an affected side that develops when a stone obstructs the ureter, causing ureteral spasm.

Renal failure A condition in which the kidneys are unable to remove accumulated metabolites from the blood or produce urine, resulting in altered fluid, electrolyte, and acid–base balance.

Renal insufficiency Decrease in the kidneys' ability to conserve sodium and concentrate the urine.

Renin–angiotensin–aldosterone system System initiated by specialized receptors in the juxtaglomerular cells of the kidney nephrons that respond to changes in renal perfusion.

Repetitive strain injury A nerve, tendon, or muscle condition that occurs when the limbs are subjected to repetitive use, awkward positions, or forced positions. Also called *repetitive motion disorder*.

Repolarization The process that returns the cell to its resting, polarized state.

Report An oral, written, or electronic communication intended to convey information to others.

Research participants Volunteers for a specific study project that meet all the inclusion criteria, have been informed of all aspects of the study, and have signed informed consent.

Reservoir A source of microorganisms.

Residual urine Urine that remains in the bladder after voiding.

Resilience/resiliency The ability to function with healthy responses, even when experiencing significant stress or adversity; the personal patterns, behaviors, or processes that promote an individual's recovery from or adaptation to adversity.

Resolution phase The fourth and final phase of the sexual response cycle is marked by a return to an unaroused state.

Resonance A hollow sound, such as the sound produced by lungs filled with air.

Resource An asset that helps nurses meet patient needs.

Resource allocation The distribution of resources among competing groups of people or programs.

Respiration The act of inhaling (inspiration) and exhaling (expiration) air to transport oxygen to the alveoli so that oxygen may be exchanged for carbon dioxide, and the carbon dioxide expelled from the body.

Respiratory acidosis A condition that is caused by an excess of dissolved carbon dioxide, or carbonic acid. It is characterized by a pH of less than 7.35 and a PaCO₂ greater than 45 mmHg. It may be caused by hypoventilation.

Respiratory alkalosis A condition that results when pH rises above 7.45 and PaCO₂ falls below 35 mmHg. It is caused by hyperventilation (unusually fast respiration, or overbreathing), leading to a carbon dioxide deficit.

Respiratory depression A decrease in the depth and rate of breathing.

Respiratory syncytial virus (RSV) A highly contagious respiratory infection that affects almost all children before 2 years of age.

Response This is the fourth component of the communication process; it is the message that the receiver returns to the sender. Also called *feed-back*.

Responsibility The specific accountability or liability associated with the performance of duties of a particular role.

Rest pain Cramping or aching pain in the calves of the legs, the thighs, and the buttocks that occurs while at rest.

Restless leg syndrome A neurologic sensorimotor disorder that is characterized by an overwhelming urge to move the legs when at rest.

Restraints Any devices or medications intended to protect the patient from injuring self or others through partially or fully limiting the patient's mobility.

Restrictive cardiomyopathy A disorder characterized by rigid ventricular walls that impair diastolic filling.

Reticular activating system Modulation of sleep–wake transitions that occurs when the reticular formation, a network of ascending nerves, relays information about alertness and arousal to the cerebral cortex and directs the brain's attention to sensory events.

Retinal detachment Separation of the retina or sensory portion of the eye from the choroid.

Retractions Visible sinking of the chest wall, or sunken areas seen between the ribs during inspiration.

Retrograde conduction Cardiac conduction against the normal flow or pattern.

Retrograde ejaculation Ejaculation that occurs with fluid traveling into the bladder instead of out through the urethra.

Retropulsion The tendency to topple backward when bumped or when rising, standing, or turning.

Retrospective audit An evaluation performed after a patient's discharge comparing the care provided to the patient with care provided to patients with similar conditions.

Reverse delegation A situation that occurs when someone with a lower rank delegates to someone with more authority.

Reverse triage A method in which the most severely injured or ill victims who require the greatest resources are treated last to allow the greatest number of victims to receive medical attention.

Revision surgery The replacement of an artificial joint after 10 years or more.

Reward deficiency syndrome The decreased ability to experience pleasure. Reward deficiency syndrome drives the person to seek external forms of gratification through the use of substances, pathologic gambling, or other high-risk behaviors.

Rh disease A rare condition where the mother is Rh negative while the child is Rh positive. If this condition arises, the mother's body will see the Rh-positive cells in the fetus as foreign, and will then produce antibodies to fight off the Rh-positive cells. May result in fetal demise in extreme cases.

Rheumatoid arthritis (RA) A chronic systemic autoimmune disease that causes inflammation of connective tissue, primarily in the joints.

Rhinorrhea Drainage of mucus from the nose. Commonly known as a runny nose.

Rhonchi A long, low-pitched sound that continues throughout inspiration suggesting a blockage of large airway passages.

Ribonucleic acid (RNA) One of two types of nucleic acid made by cells. Ribonucleic acid is made up of ribose rather than deoxyribose and contains information that has been copied from DNA (the other type of nucleic acid).

Rigidity Resistance to movement because of the involuntary contraction of all skeletal muscles.

Risk diagnosis A clinical judgment that a problem does not exist, but the presence of risk factors indicates a problem is likely to develop unless the nurse intervenes.

Risk factor A practice, behavior, or environmental factor that increases the potential of negative effects on an individual's health.

Risk management Preventive policies and processes that focus on limiting a healthcare agency's financial and legal risk associated with the delivery of care, particularly in terms of lawsuits.

Role A set of expectations about how an individual occupying one position behaves.

Role ambiguity Occurs when expectations are unclear and when people do not know how to perform their roles and/or are unable to predict the reactions of others to their behavior.

Role conflict Emotional conflict arising when competing demands are made on an individual in the fulfillment of his or her multiple social roles.

Role development Teaching and modeling the behaviors needed to successfully assume a particular role.

Role mastery Occurs when an individual's behaviors meet or exceed social expectations.

Role performance The demonstration of behaviors or actions associated with a given role.

Role strain The stress or strain experienced by an individual when incompatible behavior, expectations, or obligations are associated with a single social role.

Root cause analysis An evaluation required by the Joint Commission that is focused on identifying areas of improvement that would

decrease the likelihood of future adverse events and to develop an action plan for improvement.

Rooting reflex In response to a light touch of a finger on an infant's cheek close to the mouth, the infant's head will rotate toward the stimulation and attempt to suck the finger.

Rotational injury An injury caused by lateral flexion or twisting of the head and neck.

Round ligaments The ligaments that hold the ovaries in place.

Rupture of membranes The rupturing of amniotic membranes before the onset of labor.

Sacral promontory A projection into the pelvic cavity on the anterior upper portion of the sacrum, which serves as a landmark for pelvic measurements.

Sarcopenia The process of atrophy due to age.

Safety Decreasing risks of dangers or hazards to prevent accidents, injuries, mistakes, and harm.

Safety culture A general feeling of shared attitudes, values, practices, and beliefs which result in behaviors and feelings of responsibility for safety in all daily routines.

Safety strap body restraint Restraints used to ensure the safety of patients who are transported by wheelchair or gurney, or to protect patients confined to a bed or a chair. Also called *belt restraint*.

Salient cue The leading, most noticeable, or most important information about a patient's health status.

Saline An isotonic solution of 0.9% sodium chloride.

Sanguineous exudate A large amount of red blood cells that form a bright or dark red discharge indicating new or old damage to capillaries. Also called *hemorrhagic exudate*.

Satiety The sensation of fullness and satisfaction that should inhibit eating until the next meal.

Saturated fat A triglyceride fat that contains all of the hydrogen ions it is capable of holding.

SBAR A method of reporting information about a patient in the following order: situation, background, assessment, and recommendation.

Scaling The rating of the severity of symptoms or problems.

Scapegoat An individual who has been selected to take the blame for another individual or for a group.

Scenario planning A group process strategy that encourages members of a group to create hypothetical or "possible future" situations.

Scheduled toileting Toileting at regular intervals.

Schemes Adaptive cognitive structures formed in response to environmental stimuli according to Jean Piaget's theory of cognitive development.

Schistocytes Fragmented red blood cells.

Schizoaffective disorder A psychotic disorder with features of both schizophrenia and mood disorders.

Schizoid personality disorder (SPD) One of several personality disorders defined in the DSM-5, it is characterized by a lifelong pattern of indifference to others, absence of humor, and social isolation.

Schizophrenia The most common psychotic disorder, schizophrenia is a combination of disordered thinking, perceptual disturbances, behavioral abnormalities, affective disruptions, and impaired social competency.

Schizophreniform disorder A disorder with rapid onset of psychotic symptoms, very similar to schizophrenia, lasting less than 6 months.

Schizotypal personality disorder One of several personality disorders defined in the DSM-5, it is characterized by a pattern of disturbed interpersonal relationships, thought patterns, appearance, and behavior.

Sciatica Lumbar back pain that radiates down the posterior leg to the ankle due to irritation or compression of all or part of the sciatic nerve.

Scleral buckling A surgical procedure to correct retinal detachment.

Scoliometer A diagnostic test used to measure a patient's rib hump when in the Adam position.

Scoliosis A lateral, or sideways, curvature of the spine.

Scoop method A safe method of recapping sharps in which the cap is placed on a needle or a hard surface and the needle is guided into the cap.

Seasonal affective disorder (SAD) A mood disorder typically characterized by depression during fall and winter and normal mood or hypomania during spring and summer.

Second heart sound (S₂) The heart sound produced by closure of the semilunar valves; characterized by the syllable "dub."

Second impact syndrome (SIS) A constellation of clinical manifestations that can occur when an individual receives a second concussion before the initial concussion is completely healed.

Secondary appraisal Evaluation of an individual's available coping resources and potential options for responding to an event or circumstance.

Secondary cataracts A type of cataract that may form after surgery to treat another eye disorder, such as glaucoma, or as an effect of medication or another primary disorder.

Secondary group A group that is larger, more impersonal, and less sentimental than a primary group.

Secondary hypertension Elevated blood pressure resulting from an identifiable underlying process.

Secondary immune response Subsequent encounters with an antigen following the primary immune response that result in triggering memory cells.

Secondary infertility The inability to conceive after one or more successful pregnancies, or the inability to sustain a pregnancy.

Secondary intention healing Healing that occurs when a wound's edges cannot or should not close. Repair time is typically longer, scarring is greater, and susceptibility to infection is greater.

Secondary prevention Methods that focus on the diagnosis and treatment of disease.

Secondary sex characteristics Bodily traits that develop over time and are influenced by a person's sex but not directly involved in reproduction.

Segmental mastectomy See *Lumpectomy*.

Seizures Periods of abnormal electrical discharges in the brain that cause involuntary movement, as well as behavior and sensory alterations.

Selective perception The process of filtering out unnecessary and distracting information in order to focus on what is important at any given moment.

Selective serotonin reuptake inhibitor (SSRI) A drug that selectively inhibits the reuptake of serotonin into nerve terminals; used mostly for depression.

Selectively permeable Refers to membranes separating body fluid compartments across which solutes can move with relative ease.

Self The entirety of an individual's being, including body, sensations, emotions, and thoughts, as well as a conscious awareness of one's own being.

Self-awareness The relationship between an individual's perception of himself or herself and others' perceptions of him or her.

Self-concept The personal perception of the self formed in response to interactions with others and the environment throughout the course of an individual's lifetime.

Self-efficacy The expectation that someone can produce a desired outcome.

Self-esteem One's judgment of one's own worth.

Self-help group A group of individuals who come together to face a common problem or difficulty.

Self-quieting ability The ability of newborns to use their own resources to quiet and comfort themselves.

Semen Sperm mixed with seminal fluid, ejaculated during sexual activity.

Semiformal group A group with formalized structure, delineated hierarchy, and voluntary, but selective, membership.

Sender An individual or group who wishes to convey a message to another; can be considered the *source-encoder*.

Sensate focus A mindfulness technique commonly employed as part of sex therapy.

Sensitization An increased reaction to pain over time, or a reduced threshold for reaction to painful stimuli.

Sensory memory The earliest stage of memory in which visual input and auditory information are retained for less than a few seconds.

Sensory perception The conscious organization and translation of external data or stimuli into meaningful information.

Sensory reception The process of receiving external stimuli or data. External stimuli are visual (sight), auditory (hearing), olfactory (smell), tactile (touch), and gustatory (taste).

Sentinel event An unexpected occurrence involving death or serious physical or psychologic injury, or the risk thereof.

Sepsis 1. A whole-body inflammatory process resulting in acute illness. 2. A state of infection.

Septal defect A congenital heart defect that connects the right and left side of the heart.

Septic shock Altered perfusion resulting from a systemic infection that manifests with hypotension, delayed capillary refill, and inadequate perfusion and oxygenation of vital body tissues. Also called *septicemia*.

Septicemia See Septic shock.

Serious mental illness Mental illness that is severe enough to impair daily functioning and the ability to achieve life goals.

Seroconversion Antibody response to a disease or vaccine.

Serosanguineous exudate A clear or blood-tinged discharge commonly seen in surgical incisions.

Serotonin syndrome A condition that may occur in individuals taking two or more medications that increase serotonin levels. Symptoms include hypertension or hypotension, agitation, shivering, changes in mental status, symptoms of gastrointestinal distress, restlessness, tremor, muscle rigidity, unreactive pupils, and tachypnea.

Serous exudate A watery, clear or straw-colored discharge that accompanies mild inflammation.

Serum bicarbonate (HCO₃) A value that reflects the renal regulation of acid-base balance. The normal HCO₃ value is 24–28 mEq/L.

Serum sickness A systemic type III hypersensitivity response, usually in response to a drug such as penicillin or a sulfonamide.

Servant leadership A theory of leadership rooted in the belief that the most effective leaders are those who are motivated primarily by a desire to serve, rather than a desire to lead.

Severe sepsis Sepsis associated with acute organ failure.

Seven rights of medication administration Right person, right assessment, right drug, right dose, right route, right time, right documentation.

Sex addiction Persistent, excessive sexual behaviors.

Sex chromosomes The 23rd pair of chromosomes found in a cell's nucleus; it determines an individual's gender.

Sexism When male values, beliefs, or activities are preferred over female ones.

Sexual abuse Any sexual act that is perpetrated against someone's will including rape, attempted sexual acts, unwanted sexual contact, voyeurism, and sexual harassment. Also called *sexual violence*.

Sexual aversion disorder A disorder characterized by severe distaste for sexual activity or the thought of sexual activity.

Sexual dysfunction Any persistent disturbance in an individual's sexual response.

Sexual health A state of physical, emotional, mental, and social well-being in relation to sexuality, not merely the absence of disease, dysfunction, or infirmity. Sexual health requires a positive and respectful approach to sexuality and sexual relationships.

Sexual orientation The sexual attraction of an individual to the same sex, the opposite sex, or both sexes.

Sexual self-concept How one values oneself as a sexual being.

Sexually transmitted infections (STIs) Infections transmitted by vaginal, oral, and anal intimate contact and intercourse.

SHARE A method of handoff reporting: Standardize critical content; hardwire within your system; allow opportunity to ask questions; reinforce quality and measurement; educate and coach.

Shared governance A method that aims to distribute decision making among a group of people.

Shared leadership The concept that a professional workplace is made up of many leaders.

Shared psychotic disorder A condition that results when an individual who is in a close relationship with another person who is delusional comes to share the delusional beliefs.

Shearing force A condition that results when one tissue layer slides over another.

Shock A clinical syndrome characterized by a systemic imbalance between oxygen supply and demand.

Shock phase The initial part of an alarm reaction during which the sympathetic nervous system is suppressed and an individual may experience manifestations such as hypotension, decreased body temperature, and decreased muscle tone.

Short bowel syndrome A condition in which the transit time of ingested foods and fluids is reduced and digestive processes are impaired because of a resection of significant portions of the small intestine.

Short-term memory Information held in the brain for immediate use; what an individual has in mind at a given moment.

Shunt A natural or artificially created tunnel or passage that allows blood to flow through an area.

Sickle cell anemia An inherited chronic hemolytic anemia, sickle cell anemia is the most common form of sickle cell disease.

Sickle cell crisis Severe episodes of fever and intense pain that are the hallmark of sickle cell disease. Also called *vaso-occlusive crisis*.

Sickle cell disease A hereditary hemoglobinopathy characterized by replacement of normal hemoglobin with abnormal hemoglobin S (Hgb S) in RBCs.

Sickle cell trait Carrying one copy of the defective sickle cell gene, which can be passed on to children but does not usually cause the illness.

Sickling A process in which red blood cells take on the characteristic sickle shape following deoxygenation in patients who have sickle cell disease.

Sick-role behavior A combination of illness behaviors, such as engaging in self-care and using the healthcare system, combined with dependent behaviors, such as avoiding usual responsibilities.

Signs See Objective data.

Simple assault An unlawful physical attack by one person upon another in which neither the offender displays a weapon, nor the victim suffers any obvious severe or aggravated bodily injury involving apparent broken bones, loss of teeth, possible internal injury, severe laceration, or loss of consciousness.

Simple mastectomy The removal of a complete breast only. Compare with Radical mastectomy.

Single-parent family A family in which only one parent resides in the home and is the primary caretaker and provider for the family.

Single-payer system Healthcare coverage arising from a single source, usually the government.

Situational crisis A crisis that involves an unexpected stressor or circumstance that occurs in the course of daily living.

Situational depression A maladaptive reaction to an identifiable psychosocial stressor or stressors that occurs within 3 months after the onset of the stressor and has persisted for no longer than 6 months. Also called *adjustment disorder with depressed mood*.

Situational leader A leader who is flexible in task and relationship behaviors, considers the staff members' abilities, knows the nature of the task to be done, and is sensitive to the context or environment in which the task takes place.

Six Sigma A quality improvement program originally implemented by Motorola and General Electric that focuses on reducing variation within a process to produce a near-perfect product.

Skin turgor The elasticity of skin.

Sleep An altered state of consciousness in which an individual's perception and reaction to the environment are decreased.

Sleep apnea A disorder characterized by frequent short breathing pauses during sleep.

Sleep architecture The basic organization of normal sleep.

Sleep hygiene Interventions used to promote quality sleep at night.

Sleep loss A duration of sleep shorter than the recommended 7–8 hours a night for an adult.

Small cell carcinoma A highly malignant cancer usually associated with the lung.

SMART An acronym to provide assistance in writing a patient-centered goal statement. SMART is Single action (choose a specific, single action to focus on), Measurable (observable or measurable result), Attainable (level appropriate), Relevant (customized specifically for patient's needs), and Time-limited (specific time frame for goal to be completed).

SOAP An acronym for collective data in a progress note; it stands for subjective data, objective data, assessment, and planning.

SOAPIER Short for subjective data, objective data, assessment, plan of care, intervention, evaluation, and revision.

Sobriety A state of habitually refraining from using alcohol or drugs.

Social cognition The ability to process and apply social information accurately and effectively.

Social distance Communication characterized by a clear visual perception of the whole person. Body heat and odor are imperceptible, eye contact is increased, and vocalizations are loud enough to be overheard by others.

Social justice A framework in which to explore the complexities surrounding the variety of factors that impact diverse and vulnerable populations.

Social microcosm The concept that group members eventually behave in a therapy group the same way they behave with family and friends.

Social phobia A condition that is characterized by a pervasive, extreme fear of one or more social situations that may lead to scrutiny by others. Also called *social anxiety disorder*.

Socialization The process by which individuals learn to become members of groups and society and learn the social rules defining relationships into which they will enter.

Socialized insurance A system in which all medically necessary services are covered, including physician care, hospital services, and to some extent, prescription drugs.

Socialized medicine State government-owned and controlled health-care services.

Solitary play A stage of play in which an infant still plays primarily alone, but enjoys the presence of others.

Solute Substance that dissolves in liquid.

Solvent The component of a solution that can dissolve a solute.

Somatic cells Cells that make up the tissue of the body, with a full complement (diploid) of chromosomes, as opposed to sex cells.

Somatic pain Pain arising from nerve receptors originating in the skin or close to the surface of the body.

Somatization The process by which psychologic distress is experienced and communicated in the form of somatic symptoms.

Somatostatin A substance, believed to be a neurotransmitter, that inhibits the production of both glucagon and insulin.

Somnology The study of sleep.

Somogyi phenomenon A combination of hypoglycemia during the night with a rebound, morning rise in blood glucose to hyperglycemic levels.

Source-oriented record Patient record in which each healthcare provider or department member makes notations in a separate section or sections of the patient's chart.

Spasticity Increased muscle tone, usually with some degree of weakness.

Specific defenses Immune system responses directed against identifiable bacteria, viruses, fungi, or other infectious agents.

Specific gravity An indicator of urine concentration that can be performed quickly and easily by nursing personnel.

Specific phobia An intense or extreme fear with regard to a particular object or situation.

Specific self-esteem How much one approves of a certain parts of oneself.

Spermatogenesis The process by which mature spermatozoa are formed.

Spermicide A cream, jelly, foam, vaginal film, or suppository that is inserted into the vagina before intercourse to destroy sperm and prevent conception.

Spinal cord A continuation of the medulla oblongata, it has the ability to transmit impulses to and from the brain via the ascending and descending pathways.

Spinal cord injury (SCI) Trauma to the spinal cord that results from excessive force to the spinal column.

Spinal cord stimulation (SCS) A form of therapy used with persistent pain that has not been controlled with less invasive therapies. SCS involves the insertion of an electrode (a single channel or multichannel device) adjacent to the spinal cord in the epidural space. The electrode(s) is attached to an impulse-generator (external or implanted) that sends electric impulses to the spinal cord to control pain.

Spinal fusion The insertion of a wedge-shaped piece of bone or bone chips between the vertebrae to stabilize them and reduce pain.

Spinal shock A condition that is characterized by spinal cord swelling, decreased blood flow and blood pressure, and complete loss of motor function, spinal reflexes, and autonomic function below the level of injury.

Spiritual distress A challenge to the spiritual well-being or to the belief system that provides strength, hope, and meaning to life; a feeling of being separated from interconnectedness with others or with a higher power.

Spiritual health The overall feeling of strength, hope, and fulfillment that encourages people to find life-sustaining and enriching opportunities.

Spiritual skills Skills that help an individual find meaning in and understand the personal significance of an unexpected event.

Spiritual support Assistance to patients and families in providing meaning and sustaining courage during difficult times.

Spiritual well-being A feeling of inner peace and of being generally alive, purposeful, and fulfilled; the feeling is rooted in spiritual values and/or specific religious beliefs.

Spirituality The part of being human that seeks meaningfulness through personal connection, which may include belief in or relation-

ship with some higher power, creative force, driving being, or infinite source of energy.

Spirometry A means of measuring inhalation and exhalation, although the key measurements are forced expiratory volume over 1 second (FEV₁) and the ratio of FEV₁ to forced vital capacity (FEV₁/FVC). In other words, how much and how quickly an individual exhales air as measured by spirometry is an indicator of the degree of pulmonary function deficit.

Splint An easily adjustable device that stabilizes injuries, usually before swelling has subsided or after the reparative phase of healing.

Splitting 1. The inability to integrate contradictory experiences.
2. The inclination to perceive people or situations as one extreme or the other.

Spontaneous abortion The loss of a fetus prior to 20 weeks of gestation. Also called *miscarriage*.

Spontaneous rupture of membranes (SROM) The rupturing of membranes during the height of an intense contraction with a gush of fluid out of the vagina.

Sporadic AD One of the two basic types of Alzheimer disease, it shows no clear pattern of inheritance, although genetic factors may contribute to the disorder. Sporadic AD typically does not develop until after the age of 65. Also called *late-onset Alzheimer disease*.

Sprain A stretching or tearing of ligaments.

Sputum Mucus or mucopurulent matter expectorated from the lungs.

Squamous cell carcinoma A malignant tumor of the squamous epithelium of the skin or mucous membranes.

Staff authority The power to provide advice and support to employees or departments but not to assign tasks.

Staff development Continued staff education, planned activities to enhance role performance, and defined goals to improve patient outcomes. Also called *professional development*.

Stage of exhaustion Stage in which the body ceases to maintain its adaptation to a stressor; the stressor overwhelms the individual's ability to cope or mount a continued defense, resulting in the depletion of energy and resources.

Stage of resistance Stage in which the body attempts to move toward restoration of homeostasis while continuing to respond to the stressor.

Staghorn calculi A type of calculi associated with a urinary tract infection caused by urease-producing bacteria such as *Proteus*. These stones can grow to become very large, filling the renal pelvis and calyces. Also called *struvite calculi*.

Staging A system of classifying cancer according to the size of the tumor, involvement of lymph nodes, and metastasis to distant sites.

Standard precautions Safety guidelines, such as proper hand hygiene, use of proper protective equipment, safe injection practices, and effective management of potentially contaminated surfaces or equipment, that are designed to decrease the risk of transmitting unidentified pathogens. Also called *universal precautions* and *body substance isolation (BSI)*.

Standardized plan A nursing care plan that specifies the nursing care for groups of patients with common needs (e.g., all patients with myocardial infarction).

Standards Models of high-quality performance that may reflect the performance of industry leaders, scientific or clinical research, or recommendations of professional organizations such as the ANA.

Standards of care Guidelines used to determine what a nurse should or should not do, and may be defined as a benchmark of achievement based on a desired level of excellence.

Standards of practice A standardized description of the responsibilities for which nurses are responsible.

Standards of professional performance The behaviors expected in the professional nursing role by the American Nurses Association.

Station The location of the fetal presenting part in the maternal pelvis in relation to the ischial spine.

Status asthmaticus A severe, prolonged form of asthma that is difficult to treat.

Status epilepticus A continuous seizure that lasts for more than 30 minutes or a series of seizures during which time consciousness is not regained.

Statute of limitations The limit to the amount of time that can pass between recognition of harm and bringing a suit.

Statutory laws Laws made by any legislative branch of the government, including the U.S. Congress, state legislatures, and city and county governments.

Steatorrhea Fatty, frothy, foul-smelling stools caused by a decrease in pancreatic enzyme secretion.

Stem cell transplant The infusion of immature stem cells to replenish a patient's blood cell lines; used as an alternative to bone marrow transplantation.

Stenosis Narrowing of the valve, valve area, or great artery above the valve.

Stent A short, narrow tube inserted into the lumen of a vessel (e.g., artery) to relieve blockage.

Step-down therapy A gradual reduction in the dosage and number of drugs used in a therapeutic regimen.

Stepfamily Consists of a biological parent with children and a new spouse who may or may not have children.

Stereognosis The ability to perceive and understand an object through touch.

Stereotaxic thalamotomy An x-ray taken during neurosurgery to guide the insertion of a needle into a specific area of the brain.

Stereotyping The act of generalizing that all people in a group are the same.

Stereotypy Rigid and obsessive behavior.

Sterile field An area free of microorganisms.

Sterile technique Practices that keep an area or object free of all microorganisms. Also known as *surgical asepsis*.

Sterilization 1. A process that destroys all microorganisms, including spores and viruses. 2. An inclusive term that refers to surgical procedures that permanently prevent pregnancy.

Stigma A collection of negative attitudes and beliefs that lead people to fear, reject, avoid, and discriminate against people with mental illness.

Stillbirth Death of a fetus that occurs after 20 weeks of gestation. Also called *fetal demise* or *intrauterine fetal death (IUFD)*.

Stimulus The agent or act that stimulates a nerve receptor.

Stimulus-based stress model A model that defines stress as being a life event that requires change or adaptation on the part of the individual who is experiencing the life event.

Stoma An artificial opening in the abdominal wall; it may be permanent or temporary.

Stool Body wastes and undigested food eliminated from the bowel. Also called *feces*.

Strabismus Misalignment of the eyes.

Strain A stretching or tearing of a muscle or tendon.

Strategic planning The process of continual assessment, planning, and evaluation to guide future decisions and developments.

Stress The body's general, nonspecific response to the demands placed on it by a stressor.

Stress fracture A fracture that results from disease that has weakened the bone.

Stress mediators Hormonal triggers that are intended to promote adaptation through mechanisms such as triggering a necessary increase in heart rate and blood pressure when faced with physical danger.

Stress response Physiologic changes triggered by stress; includes activation of the neural, neuroendocrine, and endocrine systems, as well as activation of target organs.

Stressor An external influence that threatens to disrupt the equilibrium that is needed to maintain homeostasis.

Striae Whitish-silver stretch marks seen in obesity and during or after pregnancy.

Stridor A high-pitched sound within the trachea and larynx that suggests narrowing of the tracheal passage.

Stroke A condition in which neurologic deficits result from a sudden decrease in blood flow to a localized area of the brain. Also called *cerebrovascular accident* or *brain attack*.

Stroke volume (SV) The amount of blood pumped into the aorta with each contraction of the left ventricle that is measured by the difference between the end-diastolic volume and the end-systolic volume.

Structural-functional theory Focuses on family structure and function, examining family relationships and how they affect the functions of the family and relationships with other systems.

Structure standards Standards related to material resources, human resources, and general organizational structure.

Struvite calculi A type of calculi associated with a urinary tract infection caused by urease-producing bacteria such as *Proteus*. These stones can grow to become very large, filling the renal pelvis and calyces. Also called *staghorn stones*.

Subconjunctival hemorrhage Temporary, nonpathogenic hemorrhages that are caused by the changes in vascular tension or ocular pressure during birth.

Subculture groups Minority groups characterized by specific norms, beliefs, and values that coexist with a dominant culture.

Subcutaneous tissue The layer of loose connective tissue and fat cells that lies below the dermis. Also called *hypodermis*.

Subdermal implant Capsules implanted within the skin that slowly release medication, such as for contraception.

Subfertility Occurs when both partners of a couple have reduced fertility.

Subinvolution A slowing of the descent of the uterus during the post-pregnancy healing process.

Subjective data Information that is apparent to only the patient affected and can be described or verified by only that patient. Also called *symptoms* or *covert data*.

Subjective family burden The psychologic distress of family members in relation to the objective family burden of having a family member with a mental illness.

Substance abuse The use of any chemical in a fashion inconsistent with medical or culturally defined social norms despite physical, psychologic, or social adverse effects.

Substance dependence A condition in which the patient can no longer control use of the substance, continues to use it despite adverse effects, and experiences withdrawal symptoms without continued use of the substance.

Subsystem A component of a larger system.

Sucking reflex Occurs in response to a finger or nipple inserted into an infant's mouth; the infant responds by beginning to rhythmically suck on the finger.

Suctioning Aspirating secretions through a catheter connected to a suction machine or wall suction outlet.

Sudden cardiac death (SCD) Unexpected death occurring within 1 hour of the onset of cardiovascular symptoms.

Sudden infant death syndrome (SIDS) The sudden death of an apparently healthy infant that remains unexplained after other possible causes have been ruled out through autopsy, death scene investigation, and review of the medical history.

Sudden unexpected death in epilepsy (SUDEP) Sudden and unexpected death in an individual diagnosed with epilepsy.

Suicidal ideation A case of an individual constantly considering, planning, or thinking about suicide.

Suicide An act of an individual inflicting self-harm resulting in death.

Suicide attempt An act of an individual inflicting self-harm with the intent to cause death that is not successful.

Sundowning A behavioral change commonly seen in patients with dementia, characterized by increased agitation, time disorientation, and wandering behaviors during afternoon and evening hours; it is accelerated on overcast days.

Superficial basal cell carcinoma A type of skin cancer.

Superficial burn A burn that involves only the epidermal layer of the skin.

Superficial thrombophlebitis A blood clot blocking one or more veins near the skin's surface.

Superimposed preeclampsia Occurs when a woman previously diagnosed with chronic hypertension develops hypertension-related end-organ dysfunction in pregnancy or worsening hypertension that is resistant to treatment.

Supersaturated urine A condition that results when the concentration of salt in the urine is very high.

Supine On the back.

Suppuration A large quantity of cells and necrotic debris that form an opaque or milky discharge that is thicker than serous exudate. Also called *pus* or *purulent exudate*.

Suprasystem An overarching system to which smaller systems or subsystems belong. For example, the family is the suprasystem of the individual.

Surface temperature Body temperature taken at the skin's surface that may rise or fall in response to the environment.

Surfactant Specialized cells that control surface tension and keep alveoli from collapsing and sticking to themselves.

Surge capacity A community's ability to rapidly meet the increased demand for qualified personnel and resources, including healthcare resources, in the event of a disaster.

Surgical asepsis Practices that keep an area or object free of all microorganisms. Also called *sterile technique*.

Surgical debridement The process of excising a wound to the level of fascia or sequentially removing thin slices of a burn wound to the level of viable tissue.

Sutures The membranous spaces between the cranial bones of a fetus.

Swan-neck deformity Caused by rheumatoid arthritis, it is characterized by hyperextension of the proximal interphalangeal joints with compensatory flexion of the distal interphalangeal joints.

Sweat test Typically administered twice, it measures the amount of salt in the baby's sweat and is most effective for a CF diagnosis; a high level of salt confirms the diagnosis.

Switching A term used in disorders of mood and affect to describe a new illness phase (manic or depressed) without recovery.

Symmetry Equality of the size, shape, or condition of opposite sides of the body.

Sympathetic tone A state of partial smooth muscle contraction around arteries and veins.

Symphysis pubis Fibrocartilaginous joint between the pelvic bones in the midline.

Symptom See Subjective data.

Synchronized cardioversion Delivery of direct electrical current synchronized with the patient's heart rhythm.

Synclitism A condition that occurs when the sagittal suture is midway between the symphysis pubis and the sacral promontory and is felt to be aligned.

Syncope Transient loss of consciousness and muscle tone after exercise or activity.

Syndrome diagnosis A cluster of nursing diagnoses that occur together and may result in best patient outcomes if addressed at the same time.

Synovectomy Excision of synovial membrane; this procedure is used as a treatment for rheumatoid arthritis.

Synovitis Inflammation of the synovial membrane lining the articular capsule of a joint.

Syphilis A complex systemic sexually transmitted infection caused by the spirochete *Treponema pallidum*.

System A set of interacting identifiable parts or components.

Systematized delusions A manifestation of schizophrenia characterized by an extensively developed central delusional theme from which conclusions are deduced.

Systemic arthritis A form of juvenile rheumatoid arthritis that characteristically is manifested by high fever, polyarthritis, and rheumatoid rash. Systemic arthritis also affects internal organs and joints.

Systemic circulation Circulation through the left side of the heart, the aorta and its branches, the capillaries that supply the brain and peripheral tissues, the systemic venous system, and the vena cava.

Systemic infection Occurs when an invading microorganism spreads and damages different parts of the body.

Systemic inflammatory response syndrome (SIRS) Describes the body's response to a critical illness that can result from an infectious or noninfectious cause precipitating a whole-body inflammatory process.

Systemic lupus erythematosus (SLE) A chronic, inflammatory connective tissue disease.

Systemic response Results because of a widespread antibody-antigen reaction. Systemic responses include anaphylaxis, urticaria, or angioedema.

Systemic vascular resistance The force or resistance of the blood in the body's blood vessels that helps return blood to the heart.

Systems theory The study of how a system operates, including how it interacts with other systems and how its components interact with each other within the system itself.

Systole The phase of ventricular contraction.

Systolic blood pressure The maximum pressure exerted within the arteries when the heart compresses.

T lymphocyte (T cells) A type of leukocyte that matures in the thymus gland and is integral to the specific immune response.

Tachycardia An excessively fast heart rate greater than 100 bpm in an adult.

Tachypnea A respiratory rate greater than 20 bpm in adults.

Tactile Of or relating to touch.

Tangential excision The sequential removal of thin slices of a burn wound to the level of viable tissue.

Tanner stages Stages of physical growth of the breasts and pubic hair in girls and the genitalia and pubic hair in boys.

Tardive dyskinesia A condition characterized by repetitive, involuntary body movement of varying severity that may not cease after medication cessation; includes unusual tongue and face movements such as lip smacking and wormlike motions of the tongue.

Tartar A visible, hard deposit of plaque and dead bacteria that forms at the gumlines. Also called *dental calculus*.

Tau A protein found in the neurons.

Teach-back method A patient teaching strategy in which the nurse provides information to a patient and asks the patient to restate the information to ensure that the patient understands it correctly.

Teaching A system of activities intended to produce learning.

Team Two or more individuals who agree to work in tandem to accomplish a common goal.

Team nursing The delivery of individualized nursing care to a group of patients by a team led by a professional nurse.

Telangiectatic nevi Pale pink or red spots frequently found on the eyelids, nose, lower occipital bone, and nape of the neck of young children. These areas have no clinical significance and usually fade by the second birthday. Also called *stork bites*.

Telecommunication The transmission of information from one site to another, using equipment to send information in the form of signs, signals, words, or pictures by cable, radio, or other systems.

Telehealth A system that employs the use of telecommunications technologies (e.g., videoconferencing, streaming media, real-time forward-imaging, and land-based and wireless communications) to allow patients access to care that they might not otherwise be able to obtain. Also called *telemedicine* or *remote patient monitoring*.

Telenursing The provision of nursing care via **telecommunication**.

Temperament The combination of biological and physical characteristics that influence personality and behavior specific to each individual.

Tender points Tenderness that occurs in precise, localized areas, particularly in the neck, spine, shoulders, and hips.

Tendon Tissue that connects bones to muscles and carries the contractile forces from the muscle to the bone to cause movement.

Tendonitis Inflammation of a tendon.

Teratogen Any substance that adversely affects the normal growth and development of the fetus.

Terminal weaning The gradual withdrawal of mechanical ventilation when survival without assisted ventilation is not expected.

Territoriality A concept of the space and things that an individual considers as belonging to the self.

Tertiary intention healing Healing that occurs after closing a wound that has been left open for 3–5 days to allow edema or infection to resolve. Also called *delayed primary intention*.

Tertiary prevention Methods that focus on the restoration of health following an illness or accident and include rehabilitation and palliative services.

Testosterone The primary male sex hormone produced by the testes.

Tetany Tonic muscle spasms.

Tetralogy of Fallot A rare disease that consists of four defects: pulmonary stenosis, right ventricular hypertrophy, ventricular-septal defect, and an overriding aorta.

Tetraplegia Complete loss of function of the upper and lower body, including the arms, trunk, legs, and pelvic organs. Also called *quadriplegia*.

Thalassemia Inherited disorder of hemoglobin synthesis in which either the alpha or beta chains of the hemoglobin molecule are missing or defective.

Thelarche The beginning of breast development in females.

Therapeutic communication An interactive process between the nurse and the patient that helps the patient to overcome temporary stress, to get along with other people, to adjust to situations that cannot be altered, and to overcome any psychologic blocks that may stand in the way of self-realizations.

Therapeutic insemination The process of depositing semen at the cervical os or in the uterus by mechanical means.

Therapeutic relationship Nurse–patient relationship that is focused on helping patients manage problems and become better at helping themselves.

Thermoregulation The body process that balances heat production and heat loss to maintain the body's temperature.

Third heart sound (S₃) Heart sound that is sometimes heard after the second heart sound in children, young adults, and pregnant women during the third trimester. Also called a *ventricular gallop*.

Third spacing A shift of fluid from the vascular space into an area where it is not available to support normal physiologic processes.

Thoracentesis Needle insertion into the pleural space to remove fluid accumulation.

Thoracolumbar sacral orthosis (TLSO) A brace contoured to conform to the body and support the spine. Also called an *underarm brace* or *Boston brace*.

Thought blocking Speech stopped in midsentence as if the thought disappeared from the individual's head.

Thought disorders Disorders associated with schizophrenia that involve an abnormal way of thinking, such as disorganized thinking, sensory overload, thought blocking, neologisms, loose association, clang, and perseveration.

Threshold potential The point at which an action potential is capable of being generated.

Thrill A palpable vibration over the precordium or an artery.

Thromboemboli Emboli created by a blood clot.

Thrombophlebitis Sometimes called phlebitis, condition in which a blood clot forms and blocks one or more veins. Clots typically form in the legs but can form in the arms and neck in rare instances.

Throughput The process by which information, energy, or material that enters a system (input) is used by the system.

Thrush White patches that look like milk curds that adhere to the mucous membranes usually caused by an infected vaginal tract during birth, antibiotic use, or poor hand hygiene. Bleeding may occur if patches are removed.

Thyroid crisis See Thyroid storm.

Thyroid storm An extreme state of hyperthyroidism. Now extremely rare due to improved diagnosis and treatment methods. Also called *thyroid crisis*.

Thyroidectomy Surgical removal of all or part of the thyroid gland.

Thyroiditis Inflammation of the thyroid gland.

Thyrotoxicosis A disorder caused by excessive delivery of thyroid hormone to the peripheral tissues. Also called *hyperthyroidism*.

Tics Semi-involuntary movements that are sudden, repetitive, and non-rhythmic. They may involve muscle groups or vocalizations (motor or phonic).

Time constraints Deadlines for completion.

Time-out A preprocedure verification to ensure the correct procedure is being performed at the right site on the right patient.

Time priority A time constraint to complete an action.

Tine test Test in which a multiple-puncture device is used to introduce tuberculin into the skin.

Tinea pedis Fungal infection of the feet. Also called *athlete's foot*.

Tinnitus The perception of sound or noise in the ears without stimulus from the environment.

Token economies Formalized programs of contingency contracts.

Tolerance State in which a particular dose elicits a smaller response than it formerly did. With increased tolerance, the individual needs higher and higher doses to obtain the desired response.

Tone 1. The amount of tension or resistance to movement in a muscle.
2. The ability of vessels to constrict or dilate to maintain normal pressure.

Tonic-clonic seizures Alternating contraction (tonic phase) and relaxation (clonic phase) of muscles during seizure activity.

Tonic neck reflex In response to an infant's head being turned to one side while the infant lies on the back, the infant will extend the arm and leg on the side the infant faces while the opposite arm and leg will be flexed.

Tonic phase Initial phase of a generalized seizure, manifested by unconsciousness and continuous muscular contraction.

Tonicity The osmolality of a solution. Solutions may be termed *isotonic*, *hypertonic*, or *hypotonic*.

Torsades de pointes A type of ventricular tachycardia associated with a prolongation of the QT interval.

Tort A civil wrong committed against an individual or an individual's property.

Total anomalous pulmonary venous return The pulmonary veins empty into the right atrium or into veins leading to the right atrium, rather than into the left atrium.

Total lymphoid irradiation A procedure sometimes used in the treatment of rheumatoid arthritis; it decreases total lymphocyte levels.

Total quality management (TQM) A comprehensive management philosophy that improves quality and productivity by using data and statistics to improve system processes.

Toxic multinodular goiter A tumor characterized by small, discrete, independently functioning nodules in the thyroid gland tissue that secrete excessive amounts of thyroid hormone.

Toxoplasmosis Space-occupying lesions common in patients with AIDS that may cause headache, altered mental status, and neurologic deficits.

Trachoma A chronic conjunctivitis caused by *Chlamydia trachomatis*. It is a significant preventable cause of blindness worldwide.

Traction The application of a straightening or pulling force to return or maintain fractured bones in their normal anatomic position.

Traditional family An autonomous unit in which both parents reside in the home with their children, the mother assuming the nurturing role and the father providing the necessary economic resources.

Transactional leader A leader who has a relationship with followers based on an exchange of some resource valued by the follower.

Transcellular fluid One of the compartments where extracellular fluid is found. Examples of transcellular fluid are cerebrospinal, pericardial, pancreatic, pleural, intraocular, biliary, peritoneal, and synovial fluids.

Transcendence A person's recognition that there is something other or greater than the self and a seeking and valuing of that greater other, whether it is an ultimate being, force, or value.

Transcranial magnetic stimulation (TMS) A promising alternative therapy for individuals with schizophrenia that uses electromagnetic stimulus to affect brain activity in the cerebral cortex.

Transductive reasoning Connecting two events in a cause-and-effect relationship simply because they occur together in time.

Transection An injury that occurs when an individual is injured by a gunshot, stabbing, or similar force, which may partially or completely sever the spinal cord.

Transference The transfer of feelings that were originally evoked by one's parents or significant others to people in the present setting.

Transformational leader A leader who fosters creativity, risk taking, commitment, and collaboration by empowering a group to share in an organization's vision. The leader inspires others with a clear, attractive, and attainable goal and enlists them to participate in attaining the goal.

Transfusion reaction A type II or cytotoxic hypersensitivity reaction to blood of an incompatible type.

Transgender Gradations of human characteristics running from female to male; more commonly, an individual who expresses a gender identity different from that with which he or she was born.

Transient ischemic attack (TIA) A brief period of localized cerebral ischemia that causes neurologic deficits lasting for less than 24 hours. Also called a *mini-stroke*.

Transitional milk A light yellow milk that is more copious than colostrum and contains more fat, lactose, water-soluble vitamins, and calories; it usually presents between the second and fifth day following birth.

Transjugular intrahepatic portosystemic shunt (TIPS) An expandable metal stent inserted through a transcutaneous needle to channel blood from the portal vein into the hepatic vein, bypassing the cirrhotic liver.

Translational research A systematic approach of converting research knowledge into applications of healthcare for improved patient outcomes.

Transplacental immunity Passive immunity transferred from mother to infant.

Transposition of the great arteries (TGA) A congenital heart defect in which the pulmonary artery, the outflow tract for the left ventricle, and the aorta, the outflow tract for the right ventricle, are transposed.

Transsexual An individual who feels his or her sexual anatomy is not consistent with his or her gender identity.

Transurethral incision of the prostate (TUIP) Small incisions are made in the smooth muscle where the prostate is attached to the bladder in order to reduce pressure on the urethra.

Transurethral needle ablation (TUNA) A procedure that uses low-level radio-frequency through twin needles to burn away a region of the enlarged prostate in order to improve the flow of urine.

Transurethral resection of the prostate (TURP) A procedure that removes obstructing prostate tissue using the wire loop of a resectoscope and electrocautery inserted through the urethra.

Transverse diameter The largest diameter of the pelvic inlet; helps determine the shape of the inlet.

Trauma An injury to human tissues and organs resulting from the transfer of energy from an external environmental source, such as a motor vehicle, a fire, or a sharp object.

Traumatic brain injury (TBI) An injury resulting from an external physical force, such as a blow or jolt to the head, that causes displacement of the brain within the skull and disruption of normal brain function.

Traumatic cataracts A type of cataract that may result from an injury to the eye.

Tremors Rhythmic, involuntary movements or twitching of the extremities.

Triage The process of identifying priorities for implementing care.

Trial and error A group decision strategy in which the most viable solution is attempted.

Tricuspid atresia The absence of the tricuspid valve.

Tricyclic antidepressant (TCA) A class of drugs that inhibit the reuptake of both norepinephrine and serotonin into presynaptic nerve terminals. TCAs are primarily used in the pharmacotherapy of depression.

Triglycerides Substances converted from dietary fats and carbohydrates to store energy in fat cells.

Triplet Three premature ventricular contractions in a row.

Tripod position A position of sitting and leaning forward; often used by patients who are having difficulty breathing.

Trisomy An extra chromosome.

Trisomy 21 A condition that occurs when an individual born with Down syndrome has an additional full chromosome present.

Troponins Proteins released during a myocardial infarction that are sensitive indicators of myocardial damage.

Trousseau sign Spasmodic contraction of the hand and fingers in response to occlusion of the blood supply by a blood pressure cuff; caused by decreased blood calcium levels. A test used to check for hypocalcemia.

True pelvis The portion that lies below the linea terminalis; made up of the inlet, cavity, and outlet.

Truncus arteriosus A heart defect in which a single large vessel empties both ventricles and provides circulation for the pulmonary, systemic, and coronary circulations.

Trunk incurvation In response to stroking an infant's spine, the infant's pelvis will turn toward the stimulated side. Also called *Galant reflex*.

Tubal ligation A surgical procedure to clip, tie off, band, or plug the fallopian tubes to sterilize a female patient.

Tubercle A granulomatous lesion (a sealed-off colony of bacilli) formed from *Mycobacterium tuberculosis*.

G-52 Glossary

Tuberculosis (TB) A chronic, recurrent infectious disease caused by *Mycobacterium tuberculosis*. TB usually affects the lungs, but any organ can be affected.

Tubular sound The sound air makes moving through a clear and functioning trachea.

Tumor lysis syndrome (TLS) A condition that occurs when tumor cells dissolve and release intracellular contents into circulation, causing hyperkalemia, hyperuricemia, and hyperphosphatemia.

Tumor marker A protein molecule detectable in serum or other body fluids that is used to highlight suspicious regions for follow-up.

TURP syndrome A condition that is characterized by hyponatremia, decreased hematocrit, hypertension, bradycardia, nausea, and confusion.

Two-career family A family in which both partners are employed by choice or necessity. A two-career family may or may not have children.

Tympanic membrane A thin, tense membrane that separates the middle ear from the external auditory canal, protecting the middle ear from the external environment.

Tympanocentesis A surgical incision of the tympanic membrane. Also called *myringotomy*.

Tympanogram A test that provides a graph of the middle ear's ability to transmit sound.

Tympanostomy tubes Pressuring-equalizing tubes inserted to provide the middle ear with ventilation and drainage during healing.

Tympany A musical or drumlike sound produced from an air-filled stomach.

Type 1 diabetes mellitus An absolute deficiency of insulin related to pancreatic beta cell destruction that results in severe hyperglycemia and diabetic ketoacidosis, among other symptoms.

Type 2 diabetes mellitus A relative deficiency of insulin, which may be related to insulin resistance and inadequate secretion of insulin to meet body needs. Both of these components are usually present at time of diagnosis.

Ulcer A break in the GI mucosa that develops when the mucosal barrier is unable to protect the mucosa from damage by hydrochloric acid and pepsin, the gastric digestive juices.

Ulcerative colitis A chronic inflammatory bowel disorder that affects the mucosa and submucosa of the colon and rectum.

Ultrafiltration Removal of excess body water using a hydrostatic pressure gradient.

Ultrasound A test using intermittent ultrasonic waves transmitted by an alternating current to a transducer and applied to the abdomen.

Unconscious mind The part of an individual's mental life of which he or she is unaware.

Underinsured Individuals whose healthcare coverage is insufficient to meet their needs.

Undernutrition Health effects due to insufficient or diminished nutrient intake or stores. Also known as *malnutrition*.

Unifocal When a ventricular impulse arises from one ectopic site.

Unilateral lobar pneumonia A pattern of pneumonia in which bacteria tend to be distributed evenly throughout one or more lobes of a single lung.

Uninsured Individuals who are without any type of healthcare coverage.

Unipolar depression A mood disorder characterized by loss of interest in life and unresponsiveness, moving from mild to severe, with severe symptoms lasting at least 2 weeks. Also called *major depressive disorder (MDD)*.

Universal precautions (UP) Safety guidelines, such as proper hand hygiene, use of proper protective equipment, safe injection practices, and effective management of potentially contaminated surfaces or equipment, that are designed to decrease the risk of transmitting

unidentified pathogens. Also called *standard precautions* and *body substance isolation (BSI)*.

Universal protocol Established guidelines for healthcare professionals to prevent errors during surgical procedures, including wrong-site surgery.

Unlicensed assistive personnel (UAP) Members of a nursing team who assume delegated aspects of basic patient care such as bathing, assisting with feeding, and collecting specimens. UAPs include certified nurse assistants, hospital attendants, nurse technicians, and orderlies.

Unresolved bacteriuria The presence of bacteria in urine that fails to resolve with treatment.

Unsaturated fat A triglyceride fat that does not contain all of the hydrogen ions it is capable of holding.

Upper body obesity Identified by a waist-to-hip ratio of greater than 1 in men or 0.8 in women. Also called *central obesity*.

Uremia Excessive amounts of urea in the blood.

Uremic fetor A urine-like breath odor often associated with a metallic taste in the mouth.

Uremic frost Crystallized deposits of urea on the skin.

Ureteral stent A thin catheter inserted into the ureter to provide for urine flow and ureteral support.

Ureterolithotomy An incision in the affected ureter to remove a calculus.

Ureteroplasty The surgical repair of a ureter.

Urgency The sudden, strong desire to void.

Urgency factor A way to illustrate how much time can safely lapse before doing interventions without compromising patient outcomes.

Uric acid stones Develop when the urine concentration of uric acid is high.

Urinary calculi Stones in the urinary tract.

Urinary drainage system Those organs required to drain urine from the kidneys, including the ureters, urinary bladder, and urethra.

Urinary frequency The need to urinate often, specifically more than four to six times a day.

Urinary hesitancy A delay and difficulty in initiating voiding; often associated with dysuria.

Urinary incontinence Involuntary urination due to the temporary or permanent inability of the external sphincter muscles to control the flow of urine from the bladder. Also called *involuntary urination*.

Urinary reflux Backward flow of urine.

Urinary retention The accumulation of urine in the bladder and inability of the bladder to empty itself, resulting in overdistention of the bladder.

Urinary stasis Stagnation of urinary flow.

Urination Releasing urine from the urinary bladder. Also called *voiding* or *micturition*.

Uroflowmetry A method of measuring urine flow rate.

Urolithiasis The formation of stones in the urinary tract.

Urticaria Patches of pale, itchy wheals in an erythematous area. Also known as *hives*.

Uterine atony The relaxation of uterine muscle tone.

Uterosacral ligaments Ligaments that provide support for the uterus and cervix at the level of the ischial spines.

Uterus The hollow muscular organ in which the fertilized ovum is implanted and in which the developing fetus is nourished until birth.

Utilitarianism A form of consequentialist theory that views a good act as one that brings the most good and the least harm for the greatest number of people. This is called the principle of utility.

Utility See Utilitarianism.

Utilization review An evaluation of the use of resources to identify areas of overuse, misuse, and underuse.

Uveitis Inflammation of the middle layer of the eye called the uvea.

Vaccine Suspensions of whole or fractionated bacteria or viruses that have been treated to make them nonpathogenic; introduced by immunization to provoke active immunity.

Vacuum extraction An obstetric procedure used by physicians and CNMs to assist the birth of a fetus by applying suction to the fetal head.

Vagina The muscular and membranous tube that connects the external genitals with the uterus.

Vaginal birth after cesarean (VBAC) An option for a mother to choose a trial of labor and vaginal birth after having a cesarean for a previous child, provided the previous cesarean was required due to a nonrecurring indication and the mother meets the guidelines established by the American College of Obstetricians and Gynecologists.

Vaginismus The involuntary spasm of the outer one third of the vaginal muscles, making penetration of the vagina painful and sometimes impossible.

Validation The act of verifying the accuracy and factuality of data.

Valsalva maneuver Forced exhalation against a closed glottis.

Values Personal beliefs about truth and the worth of behaviors or objects; standards that influence behavior.

Values clarification A process of consciously identifying, examining, and developing individual values that helps nurses gain the ability to choose actions on the basis of deliberately adopted values.

Variable decelerations A condition that occurs if the umbilical cord becomes compressed, reducing blood flow between the placenta and fetus. Fetal hypertension stimulates the baroreceptors in the aortic arch and carotid sinuses, slowing the fetal heart rate.

Variance 1. An unmet goal. 2. An incident or accident that affects a patient or a visitor in a healthcare facility.

Vasectomy A procedure to surgically sever the vas deferens on both sides of the scrotum to sterilize a male patient.

Vasogenic shock Shock that results from widespread vasodilation and decreased peripheral resistance. Also called *distributive shock*.

Vaso-occlusive crisis See Sick cell crisis.

Vegan A type of vegetarian diet that excludes all animal and fish products, including dairy, meat, eggs, and honey.

Venous stasis The collection and stagnation of blood in the lower extremities.

Venous thrombectomy Surgical removal of a blood clot from the femoral vein to prevent pulmonary embolism or gangrene.

Venous thrombosis A condition in which a blood clot (thrombus) forms on the wall of a vein, accompanied by inflammation of the vein wall and some degree of obstructed venous blood flow. Also called *thrombophlebitis*.

Ventilation The exchange of oxygen and carbon dioxide.

Ventilation-perfusion (V-Q) The movement of oxygen across the alveolar-capillary membrane into a well-perfusing capillary.

Ventricular aneurysm An outpouching of the ventricular wall that does not contract during systole, causing stroke volume to decrease.

Ventricular bigeminy A premature ventricular contraction following each normal beat.

Ventricular gallop (S₃) Heart sound sometimes heard after the second heart sound in children, young adults, and pregnant women during the third trimester. Also called the *third heart sound*.

Ventricular septal defect (VSD) An opening in the ventricular septum that causes increased pulmonary blood flow.

Ventricular trigeminy A premature ventricular contraction every third beat.

Veracity A moral principle that holds that an individual should tell the truth and not lie.

Verbal abuse The use of berating, humiliating, ridiculing, blaming, or threatening language toward an individual.

Verbal communication Transmitting information through the spoken or written word.

Vernix caseosa A whitish, cheeselike substance that covers a fetus while in utero.

Vertical rotation The degree of rotation of the vertebrae.

Vertical transmission Perinatal transmission of an infection, such as the human immunodeficiency virus, from mother to infant.

Vertigo A sensation of whirling or rotation.

Very-low-calorie diets A program providing a protein-sparing modified fast (400–800 kcal/day or less) under close medical supervision.

Vesicoureteral reflux A condition in which urine moves from the bladder back toward the kidney. A common risk factor in children who develop pyelonephritis that may also be seen in adults whose bladder outflow is obstructed.

Vesicular sounds The soft and breezy sounds of air moving in and out of the lobes at the alveolar level.

Vestibulitis Pain of the outer portion of the vagina upon touch or attempted penetration.

Vibration A series of vigorous quiverings produced by hands that are placed flat against the patient's chest wall.

Violence The use of excessive force against other individuals or oneself, often resulting in physical or psychological injuries or death.

Virchow triad Three factors associated with thrombophlebitis: stasis of blood, vessel damage, and increased blood coagulability.

Virions Virus particles unable to grow and reproduce outside a host.

Virulence The ability of a microorganism to produce disease.

Virus A type of microorganism that must enter living cells in order to reproduce.

Visceral Of or relating to any large organ in the body.

Visceral pain Pain arising from body organs. It is dull and poorly localized because of the low number of nociceptors.

Viscosupplementation A treatment for osteoarthritis of the knee that involves injecting lubricating substances directly into the knee.

Visual Of or relating to sight.

Vitamins Micronutrient compounds that are involved in regulating body functioning. Most vitamins, with the exceptions of vitamins D and K, cannot be manufactured within the body and must be consumed through dietary intake.

Vitiligo An autoimmune disorder that results in loss of melanin in patches of the face, hands, or groin.

Voiding Releasing urine from the urinary bladder. Also called *urination* or *micturition*.

Voiding cystourethrography Use of a contrast medium and x-rays to assess the bladder and urethra when filled and during voiding.

Volatile acid Acids eliminated from the body as a gas.

Volkman contracture Impaired mobility of the arm and inability to extend the arm completely, which is a common complication of elbow fractures.

Voluntary admission The detention of a patient in a psychiatric or medical facility at the patient's request.

Voluntary insurance Healthcare insurance that provides no guarantee of universality because coverage may be expensive and difficult to purchase.

Vomiting The forceful expulsion of the contents of the upper gastrointestinal tract resulting from contraction of muscles in the gut and abdominal wall.

G-54 Glossary

Vulnerability An individual's susceptibility to react to a specific stressor.

Vulnerability factors A practice, behavior, or environmental factor that increases the potential of an individual becoming a victim of violence.

Vulnerable populations Social groups with inadequate access to health-care because they lack resources and are exposed to more risk factors.

Vulva The external female genitals.

Vulvodynia Constant, unremitting burning that is localized to the vulva with an acute onset.

Warm zone When a disaster occurs, this zone, located at least 300 feet from the outer edge of a hot zone, is where decontamination occurs and rapid triage and emergency treatment are given to stabilize victims. Also called the *yellow zone*, *contamination zone*, or *contamination reduction zone*.

Water An essential nutrient for the body's survival, it contributes to fluid balance and plays an important role in nerve and muscle functioning and in the transport of nutrients to all body systems.

Weaning 1. The process of removing ventilator support and reestablishing spontaneous, independent respirations. 2. The process of discontinuing breastfeeding and transitioning an infant to another feeding method.

Well-being A subjective perception of feeling well that can be described objectively and measured.

Wellness A state of well-being that encompasses self-responsibility, dynamic growth, nutrition, physical fitness, emotional health, preventive healthcare, and the whole being of the individual.

Wellness diagnosis A term that describes human responses to levels of wellness in an individual, family, or community that have a readiness for enhancement. For example, *Readiness for Enhanced Coping*.

Wernicke encephalopathy A condition typically seen in people with alcoholism that is characterized by ataxia (lack of coordination), abnormal eye movements, and confusion.

Wheezing A high-pitched whistling sound most often heard on expiration and caused by the narrowing of bronchi; wheezes can also be heard on inspiration.

Whiplash An injury that results from sudden impact to a motor vehicle that causes an individual's head and neck to be forcibly contorted, resulting in injury to the spine.

Whistleblower A nurse or other individual who goes outside of an organization for the public's best interest when the organization fails to follow procedures regarding safety and patient care.

Whistleblowing The act of going outside of an organization for the public's best interest when an organization fails to follow procedures regarding safety and patient care.

White blood cells (WBCs) See Leukocytes.

Withdrawing or withholding life-sustaining therapy (WWLST) The withdrawal of extraordinary means of life support, such as removing a ventilator or withholding special attempts to revive a patient, and allowing the patient to die of the underlying medical condition.

Work ethic A belief in the importance and moral worth of work.

Workplace bullying Malicious, repeated, harmful mistreatment of an individual with whom one works, regardless of whether that individual is an equal, a superior, or a subordinate.

Workplace violence Any physical assault, threatening behavior, or verbal abuse occurring in the workplace.

Worldview The way in which people in a culture perceive ideas and attitudes about the world, other people, and life in general.

Worst-case scenario Technique designed to help groups make decisions that involve risk. The worst-case outcome is outlined for each alternative, and then the scenario with the comparatively best outcome is selected as the preferred outcome. This technique helps ensure that the "least of all evils" is selected.

Wrong-site surgery (WSS) A surgical operation that is performed at the wrong location on a patient's body due to error.

Xenograft Skin used for transplantation that was obtained from an animal, usually a pig. Also called *heterograft*.

Xenophobia The fear or dislike of people different from one's self.

Xerostomia Dry mouth that occurs when an individual's supply of saliva is reduced.

Zollinger-Ellison syndrome A form of peptic ulcer disease caused by a gastrinoma, or gastrin-secreting tumor of the pancreas, stomach, or intestines.

Zygote A fertilized egg.

Combined Index

Red type indicates a concept.
Bold type indicates an exemplar.
f indicates an entry from a figure.
t indicates an entry from a table or box.
