Figure 33-84 » The newborn can bring hand to mouth as a self-soothing activity.

handled—whether during spontaneous activity, prone placement, or horizontal holding—and overall assessment of body tone as the newborn reacts to all stimuli.

- **Variations.** Frequency of alert states, state changes, color changes (throughout all states as examination progresses), activity, and peaks of excitement are assessed.
- **Self-quieting activity.** This assessment is based on how often, how quickly, and how effectively newborns can use their resources to quiet and console themselves when upset or distressed. Considered in this assessment are such self-consolatory activities as putting a hand to mouth, sucking on a fist or the tongue, and attuning to an object or sound (**Figure 33-84** »). The newborn's need for outside consolation must also be considered (e.g., seeing a face; being rocked, held, or dressed; using a pacifier; and being swaddled).
- **Cuddliness or social behaviors.** This area encompasses the newborn's need for, and response to, being held. These behaviors influence the couple's self-esteem and feelings of acceptance or rejection. Cuddling also appears to be an indicator of personality. Cuddlers appear to enjoy, accept, and seek physical contact; are easier to placate; sleep more; and form earlier and more intense attachments. Noncuddlers are active, restless, have accelerated motor development, and are intolerant of physical restraint. Smiling, even as a grimace reflex, greatly influences parent-newborn feedback. Parents identify this response as positive.

Once assessment has been completed, the nurse reviews the data and analyzes it to determine the newborn's specific needs.

Diagnosis

Nursing diagnoses of the newborn during the transition period are based on an analysis of the assessment findings. Physiologic alterations of the newborn form the basis of many nursing diagnoses, as does the family members'

incorporation of them in caring for the new baby. Nursing diagnoses that may apply to newborns include the following:

- *Ineffective Airway Clearance* related to presence of mucus and retained lung fluid
- *Ineffective Thermoregulation* related to evaporative, radiant, conductive, convective heat losses, immature hypothalamic response
- *Acute Pain* related to heelsticks for glucose or hematocrit tests or a vitamin K injection.

(NANDA-I © 2014)

Examples of nursing diagnoses that may apply during daily care of the newborn include the following:

- *Ineffective Breathing Pattern* related to periodic breathing
- *Imbalanced Nutrition: Less Than Body Requirements* related to limited nutritional and fluid intake and increased caloric expenditure
- *Impaired Urinary Elimination* related to meatal edema secondary to circumcision
- *Risk for Infection* related to umbilical cord healing, circumcision site, immature immune system, or potential birth trauma (forceps or vacuum extraction birth)
- *Readiness for Enhanced Breastfeeding* related to lack of information about breastfeeding
- *Readiness for Enhanced Parenting* related to lack of information about basic baby care, male circumcision, and formula feeding
- *Interrupted Family Processes* related to integration of newborn into family or demands of newborn care and feeding
- *Risk for Injury* related to reabsorption of bilirubin and decreased defecation.

Nursing diagnoses that may apply to the newborn's family include the following:

- *Readiness for Enhanced Parenting* related to appropriate behavioral expectations for the newborn
- *Readiness for Enhanced Family Processes* related to integration of newborn into family unit or demands of newborn care and feeding

(NANDA-I © 2014).

Planning

The broad goals of nursing care during this period are the following:

- The newborn will be healthy and well.
- The family unit will function well.

The nurse meets the first goal by providing comprehensive care to the newborn in the mother–baby unit. The nurse meets the second goal by teaching family members how to care for their new baby and by supporting their efforts so that they feel confident and competent. The nurse must be knowledgeable about family adjustments that need to be made as well as about the healthcare needs of the newborn. It is important for the family to return home with the positive

feeling that they have the support, information, and skills to care for their newborn. Equally important is the need for each member of the family to begin a unique relationship with the newborn. The cultural and social expectations of individual families and communities affect the way in which normal newborn care is carried out.

Implementation

At the moment of birth, numerous physiologic adaptations begin to take place in the newborn's body. Because of these dramatic changes, newborns require close observation to determine how smoothly they are making the transition to extrauterine life. Newborns also require specific care that enhances their chances of making this transition successfully. Immediately after birth, the baby is formally admitted to the healthcare facility by the nurse.

The nurse reviews the mother's prenatal record for information concerning possible risk factors for the newborn. These include infectious diseases screening results, drug or alcohol use, alterations to normal pregnancy and delivery, prolonged rupture of membranes, instrument or vacuum delivery, use of narcotic analgesia, presence of meconium, psychosocial concerns such as depression or anxiety, and any other maternal data that may impact the newborn's ability to successfully transition to the extrauterine environment.

Care of the newborn is based on an analysis of assessment findings and the goals of the plan of care. This section covers some of the more common or essential interventions, both in the initial period immediately following birth and in the transition period that continues until the newborn and family are discharged.

Initial Care of the Newborn

The nurse responsible for the newborn first checks and confirms the newborn's identification with the mother's identification and then obtains and records all significant information.

MAINTENANCE OF A CLEAR AIRWAY For the neonate with any initial respiratory distress or excessive oral secretions, the nurse should position the newborn on the back (or the side if secretions are copious) and suction the airway using a bulb syringe. When possible, this procedure should be delayed for 10–15 minutes after birth to reduce the potential for severe vasovagal reflex apnea. Excessive secretions should be reported to the primary healthcare provider because they may indicate tracheoesophageal fistula.

MEASUREMENT OF VITAL SIGNS In the absence of any newborn distress, the nurse continues to admit the newborn by measuring vital signs. The vital signs for a healthy term newborn should be monitored at least every 30 minutes until the newborn's condition has remained stable for 2 hours (AAP & ACOG, 2012). The newborn's respirations may be irregular yet still be considered normal. Periodic breathing, lasting only 5–15 seconds with no color or heart rate changes, is considered to be normal. The normal pulse range is 110–160 beats/min (a pulse anywhere from 100 to 205 beats/min may be considered normal), and the normal

respiratory range is 30–60 breaths/min (during the first several hours after birth it is not uncommon for the newborn to have a respiratory rate as high as 80 breaths/min).

PROMOTION OF THERMOREGULATION An NTE is best achieved by performing the newborn assessment and interventions with the newborn unclothed and under a radiant warmer. The radiant warmer's thermostat is controlled by the thermal skin sensor taped to the newborn's abdomen, upper thigh, or arm. The sensor indicates when the newborn's temperature exceeds or falls below the acceptable temperature range. The nurse should be aware that leaning over the newborn may block the radiant heat waves from reaching the neonate. In addition to placing the baby under a radiant warmer, it is common practice in some institutions to cover the newborn's head with a cap to prevent further evaporative heat loss (Blackburn, 2013).

When the newborn's temperature is normal and vital signs are stable (2–4 hours after birth), the baby may be given a sponge bath. However, this admission bath may be postponed for some hours if the newborn's condition dictates or if the parents wish to give the first bath. In light of early discharge practices (12–48 hours), healthy term newborns can be bathed safely immediately after the admission assessment is completed. The baby is bathed while still under the radiant warmer. The newborn may be bathed in the parents' room and by the parents. Bathing the newborn offers an excellent opportunity for the nurse to teach and welcome parents' involvement in the care of their baby.

The nurse rechecks the baby's temperature after the bath and, if it is stable, dresses and places the newborn in an open crib at room temperature. If the baby's axillary temperature is below 36.5°C (97.7°F), the nurse returns the baby to the radiant warmer. The rewarming process should be gradual to prevent hyperthermia. Once the newborn is rewarmed, the nurse implements measures to prevent further neonatal heat loss, such as keeping the newborn dry, swaddled in one or two blankets with a hat on, and away from cool surfaces or instruments. Newborns are often "double-wrapped" in two or more blankets for temperature maintenance.

VITAMIN K DEFICIENCY A prophylactic injection of phytonadione (vitamin K) is recommended to prevent hemorrhage, which can occur because of low prothrombin levels in the first few days of life. The potential for hemorrhage is considered to result from the absence of intestinal bacterial flora, which influences the production of vitamin K in the newborn. Newborns should receive a single parenteral dose of 0.5–1 mg of phytonadione within 1 hour of birth; this dose may be delayed until after the first breastfeeding in the childbirth/birthing area (AAP & ACOG, 2012; Marcewicz, 2014). Current recommendations underscore the need for treatment in babies who are exclusively breastfed (Blackburn, 2013).

The phytonadione injection is given intramuscularly in the middle third of the vastus lateralis muscle, located in the lateral aspect of the thigh (**Figure 33–85** >>). Before injecting, the nurse must thoroughly clean the newborn's

Figure 33–85 >> Injection sites. The middle third of the vastus lateralis muscle is the preferred site for intramuscular injection in the newborn.

skin site for the injection with a small alcohol swab. The nurse uses a 27-gauge, 1/2 in. to 5/8 in. needle for the injection (**Figure 33–86** >>). An alternative site is the rectus femoris muscle in the anterior aspect of the thigh. However, this site is near the sciatic nerve and femoral artery, so injections here should be done with caution.

Source: Marlon Lopez/MMG1 Design/Shutterstock.

Figure 33–86 >> Procedure for vitamin K injection. Cleanse the area thoroughly with an alcohol swab and allow the skin to dry. Hold the tissue of the upper outer thigh (vastus lateralis muscle) taut, and quickly insert a 27-gauge, 1/2 in. to 5/8 in. needle at a 90-degree angle to the thigh. Aspirate, then slowly inject the solution to distribute the medication evenly and minimize the baby's discomfort. Remove the needle and gently massage the site with an alcohol swab.

PREVENTION OF EYE INFECTION The nurse is responsible for giving the legally required prophylactic eye treatment for *Neisseria gonorrhoeae*, which may have infected the newborn of an infected mother during the birth process. A variety of topical agents appear to be equally effective. Ophthalmic ointments that are used include 0.5% erythromycin (Ilotycin Ophthalmic), 1% tetracycline, or per agency protocol (AAP & ACOG, 2012). All of these ointments are also effective against chlamydia, which has a higher incidence rate than gonorrhea.

Successful eye prophylaxis requires that the medication be instilled into the lower conjunctival sac of each eye (**Figure 33-87** >>). The nurse massages the eyelid gently to distribute the ointment. Instillation may be delayed up to 1 hour after birth to allow eye contact during parent–newborn bonding.

Eye prophylaxis medications can cause chemical conjunctivitis, which gives the newborn some discomfort and may interfere with the newborn’s ability to focus on the parents’ faces. The resulting edema, inflammation, and discharge may cause concern if the parents have not been informed that the side effects will clear in 24–48 hours and that this prophylactic eye treatment is necessary for the newborn’s well-being.

EARLY ASSESSMENT OF NEONATAL DISTRESS During the first 24 hours of life, the nurse is constantly alert for signs of distress. If the newborn is with the parents during this period, the nurse must take extra care to teach them how to maintain their newborn’s temperature, recognize the hallmarks of newborn distress, and respond immediately to signs of respiratory problems. The parents learn to observe the newborn for changes in color or activity, grunting or “sighing” sounds with breathing, rapid breathing with chest

retractions, or facial grimacing. Their interventions include nasal and oral suctioning with a bulb syringe, positioning, and vigorous fingertip stroking of the newborn’s spine to stimulate respiratory activity if necessary. The nurse must be available immediately if the newborn develops distress.

INITIATION OF FIRST FEEDING The timing of the first feeding varies depending on whether the newborn is to be breastfed or formula-fed and whether there were any complications during pregnancy or birth, such as maternal diabetes or intrauterine growth restriction. The nurse should encourage mothers who choose to breastfeed their newborns to put the baby to the breast during the newborn’s first period of reactivity. This practice should be encouraged because successful, long-term breastfeeding during infancy appears to be related to beginning such feedings in the first few hours of life. Sleep–wake states affect feeding behavior and need to be considered when evaluating the newborn’s sucking ability.

Formula-fed newborns usually begin the first feedings by 5 hours of age, during the second period of reactivity when they awaken and appear hungry. Signs indicating newborn readiness for the first feeding are licking of the lips, placing a hand in or near the mouth, active bowel sounds, absence of abdominal distention, and a lusty cry that quiets with rooting and sucking behaviors when a stimulus is placed near the lips. Observing the earlier, more subtle cues that the baby is ready to nurse provides an opportunity to teach the parents to recognize these cues and respond before the baby is frustrated and crying.

SAFETY ALERT Newborns with respiratory distress should not be fed orally because of an increased risk of aspiration.

FACILITATION OF PARENT–NEWBORN ATTACHMENT To facilitate parent–newborn attachment, eye-to-eye contact between the parents and their newborn is extremely important during the early hours after birth, when the newborn is in the first period of reactivity. The newborn is alert during this time, the eyes are wide open, and the baby often makes direct eye contact with human faces within optimal range for visual acuity. It is theorized that this eye contact (*en face*) is an important foundation of establishing attachment in human relationships (Cassidy, Jones, & Shaver, 2013). Parents who cannot be with their newborns in this first period because of maternal or neonatal distress may need reassurance that the bonding process can proceed normally as soon as both mother and baby are stable.

Another situation that can facilitate attachment is the interactive bath. While bathing their newborn for the first time, parents attend closely to their baby’s behavior. The bath is also an opportune time for the nurse to educate patients about normal variations in the newborn, and to allow parents to gain confidence handling and interacting with the newborn.

Care of the Newborn Following Transition

Once a healthy newborn has demonstrated successful adaptation to extrauterine life, the neonate needs appropriate observations for the first 6–12 hours after birth and the remainder of his or her stay in the birthing facility.

Figure 33-87 >> Ophthalmic ointment. Retract the lower eyelid outward to instill a 1-cm-(0.25-in.)-long strand of ointment from a single-dose tube along the lower conjunctival surface. Make sure that the tip of the tube does not touch the eye.

MAINTENANCE OF CARDIOPULMONARY FUNCTION The nurse assesses vital signs every 4–8 hours or more, depending on the newborn's status. The nurse places the newborn on the back (supine) for sleeping and keeps a bulb syringe within easy reach should the baby need oral–nasal suctioning. If the newborn has respiratory difficulty, the nurse clears the airway. Vigorous fingertip stroking of the baby's spine will frequently stimulate respiratory activity. A cardiorespiratory monitor may be used on newborns who are not being observed at all times and are at risk for decreased respiratory or cardiac function. Indicators of risk are pallor, cyanosis, ruddy color, apnea, and other signs of instability. Changes in skin color may indicate the need for closer assessment of temperature, cardiopulmonary status, hematocrit, glucose, and bilirubin levels.

PROMOTION OF ADEQUATE HYDRATION AND NUTRITION The nurse records caloric and fluid intake and enhances adequate hydration by maintaining an NTE and offering early and frequent feedings. Early feedings promote gastric emptying and increase peristalsis, thereby decreasing the potential for hyperbilirubinemia by decreasing the amount of time fecal material is in contact with the enzyme beta-glucuronidase in the small intestine. This enzyme frees the bilirubin from the feces, allowing it to be reabsorbed into the vascular system.

The nurse records voiding and stooling patterns. The first voiding and the first passage of stool should occur within 24–48 hours. If they do not occur, the nurse continues the normal observation routine while assessing for abdominal distention, bowel sounds, hydration, fluid intake, and temperature stability.

The nurse weighs the newborn at the same time each day for accurate comparisons. The newborn must be kept warm during the weighing. A weight loss of up to 10% for term newborns is considered to be within normal limits during the first week of life. This weight loss is the result of limited intake, loss of excess extracellular fluid, and passage of meconium. Parents should be told about the expected weight loss, the reason for it, and the expectations for regaining the birth weight. Birth weight is usually regained by 2 weeks if feedings are adequate.

Excessive handling can cause an increase in the newborn's metabolic rate and caloric use and also cause fatigue. The nurse should be alert to the newborn's subtle cues of fatigue, including a decrease in muscle tension and activity in the extremities and neck as well as loss of eye contact, which may be manifested by fluttering or closure of the eyelids. The nurse quickly ceases stimulation when signs of fatigue appear. The nurse demonstrates to parents the need to be aware of newborn cues and to wait for periods of alertness for contact and stimulation.

The nurse also assesses the woman's comfort and latch-on techniques if breastfeeding. If the woman is not breastfeeding, the nurse assesses the mother's bottle-feeding techniques.

PROMOTION OF SKIN INTEGRITY Newborn skin care, including bathing, is important for the health and appearance of the individual newborn and for infection control within the nursery. Ongoing skin care involves cleansing the

buttock and perianal areas with fresh water and cotton or a mild soap and water during diaper changes. If commercial baby wipes are used, those without alcohol should be selected. Perfume-free and latex-free wipes are also available.

The nurse should assess the umbilical cord for signs of bleeding or infection. Removal of the cord clamp within 24–48 hours of birth reduces the chance of tension injury to the area. Keeping the umbilical stump clean and dry can reduce the chance for infection. Many types of routine cord care are practiced, including the use of triple dye, an antimicrobial agent (e.g., bacitracin), or application of 70% alcohol to the cord stump. These practices are largely based on tradition rather than current research findings. The skin absorption and toxicity of triple-dye agents in newborns have not been carefully studied. Studies have shown that alcohol used alone is not effective in preventing umbilical cord colonization and infection (omphalitis) (AAP & ACOG, 2012). Folding the diaper down to avoid covering the cord stump can prevent contamination of the area and promote drying. The nurse is responsible for cord care per agency policy. It is also the nurse's responsibility to instruct parents in caring for the cord and observing for signs and symptoms of infection after discharge, such as foul smell, redness and drainage, localized heat and tenderness, or bleeding.

PROMOTION OF SAFETY Safety of the newborn is paramount. It is essential for the nurse and other caregivers to verify the identity of the newborn by comparing the numbers and names on the identification bracelets of the mother and newborn before giving a baby to a parent (AAP & ACOG, 2012).

The nurse should teach parents the following measures to prevent abduction and provide for safety:

- Parents should check that identification bands are in place as they care for their baby; if the bands are missing, parents should ask that they be replaced immediately.
- Parents should allow only individuals with proper birthing-unit picture identification to bring and/or remove the baby from the room. If parents do not know the staff person, they should call the nurse for assistance.
- Parents should report the presence of any suspicious individuals on the birthing unit.
- Parents should never leave their baby alone in their room. If they walk in the halls or take a shower, parents should have a family member watch the baby or should return the baby to the nursery.
- A parent who is feeling weak, faint, or unsteady should not lift the baby. Instead, the parent should call for assistance.
- Parents should always keep an eye and a hand on the baby when the newborn is out of the crib.
- Parents should ask visitors to leave if they have a cold, diarrhea, discharge from sores, or a contagious disease. Newborns need protection from infection even though they do possess some immunity.

PREVENTION OF COMPLICATIONS Newborns are at continued risk for the complications of hemorrhage, late-onset cardiac symptoms, and infection. Pallor may be an early sign of hemorrhage and must be reported to the

healthcare provider. The newborn with pallor is placed on a cardiorespiratory monitor to permit continuous assessment. Several newborn conditions put newborns at risk for hemorrhage. Cyanosis that is not relieved by oxygen administration requires emergency intervention, may indicate a congenital cardiac condition or shock, and requires ongoing assessment.

Infection in the nursery is best prevented by requiring that all personnel who have direct contact with newborns scrub for 2–3 minutes from the fingertips up to and including the elbows at the beginning of each shift. Each caregiver's hands must also be washed with soap and rubbed vigorously for 15 seconds before and after contact with every newborn and after touching any soiled surface, such as the floor or one's hair or face. Parents are instructed to practice appropriate hand hygiene before touching the baby. They are also instructed that anyone holding the baby should practice good hand hygiene, even after the family returns home. In some clinical settings family members are asked to wear gowns (preferably disposable) over their street clothes during their contact with newborns. These are good opportunities for the nurse to reinforce the efficacy of hand hygiene in preventing the spread of infection.

Jaundice in newborns is caused by the accumulation of the pigment bilirubin in the skin. Jaundice occurs in most newborns. Most jaundice is benign, but because of the potential toxicity of bilirubin, newborns must be monitored to identify those who might develop severe hyperbilirubinaemia and, in rare cases, acute bilirubin encephalopathy or kernicterus (AAP & ACOG, 2012). Current recommendations include obtaining a total serum bilirubin level in any neonate who is visibly jaundiced in the first 24 hours of life and obtaining either a serum or transcutaneous bilirubin level before discharge. Nomograms for evaluating risk factors based on bilirubin levels and age of the neonate are available.

CIRCUMCISION **Circumcision** is a surgical procedure in which the prepuce, an epithelial layer covering the penis, is separated from the glans penis and excised. This procedure permits exposure of the glans for easier cleaning. Controversy exists over the need to perform circumcisions.

Originally a religious rite practiced by Jews and Muslims, circumcision has gained widespread cultural acceptance in the United States but is much less common in Europe. Many parents choose circumcision because they want their male child to have a physical appearance similar to that of his father or the majority of other boys; some feel that it is expected by society. Another commonly cited reason for circumcising newborn males is to prevent the need for anesthesia, hospitalization, pain, and trauma if the procedure is needed later in life (AAP & ACOG, 2012). Failure to circumcise is a risk factor related to penile cancer in later life. During the prenatal period, the nurse ensures that parents have clear and current information regarding the risks and benefits of circumcision and supports their decision regarding the choice to circumcise.

As in the past, recommendations regarding circumcision have varied. The 1999 AAP policy statement was reaffirmed in 2005 and does not recommend routine circumcision, but it does acknowledge that medical indications for circumcision

still exist (AAP & ACOG, 2012). The policy recommends that analgesia be used during circumcision to decrease procedural pain (AAP & ACOG, 2012); the dorsal penile nerve block and subcutaneous ring block are the most effective options (Cloherty et al., 2012). If a circumcision is to be performed, it should be done using the least painful method. Studies show that using oral sucrose for painful procedures can be effective in reducing pain for newborns and should be used with other nonpharmacologic measures to enhance its effectiveness (AAP & ACOG, 2012).

Circumcision should not be performed if the newborn is premature or compromised, has a known bleeding problem, or is born with a genitourinary defect, such as hypospadias or epispadias, which may necessitate use of the foreskin in future surgical repairs.

The nurse plays an essential role in providing parents with current information regarding the medical, social, and psychologic aspects of newborn circumcision. A well-informed nurse can allay parents' anxiety by sharing information and allowing them to express their concerns. In order for parents to make a truly informed decision, they must be knowledgeable about the potential risks and outcomes of circumcision. Hemorrhage, infection, difficulty in voiding, separation of the edges of the circumcision, discomfort, and restlessness are early potential problems. Later, there is a risk that the glans and urethral meatus may become irritated and inflamed from contact with the ammonia from urine. Ulcerations and progressive stenosis may develop. Adhesions, entrapment of the penis, and damage to the urethra are all potential complications of circumcision that could require surgical correction (AAP & ACOG, 2012).

The parents of a male newborn who will not be circumcised require information from the nurse about good hygiene practices. The nurse tells the parents that the foreskin and glans are two similar layers of cells that separate from each other. The separation process begins prenatally and is normally completed between 3 and 5 years of age. In the process of separation, sterile sloughed cells build up between the layers. This buildup looks similar to the smegma that is secreted after puberty, and it is harmless. Occasionally during the daily bath, the parent can gently test for retraction. If retraction has occurred, daily gentle washing of the glans with soap and water is sufficient to maintain adequate cleanliness. The parents should later teach the child to incorporate this practice into his daily self-care activities. Most uncircumcised males have no difficulty doing so.

If circumcision is desired, the procedure is performed when the newborn is well stabilized and has received his initial physical examination by a healthcare provider. The parents may also choose to have the circumcision done after discharge. However, parents need to be advised that if the baby is older than 1 month, the current practice is to hospitalize him for the procedure.

Before a circumcision, the nurse ensures that the physician has explained the procedure, determines whether the parents have any further questions about the procedure, and verifies that the circumcision permit is signed. As with any surgical procedure, the neonate's identification band should be checked to verify his identity before the procedure begins. The nurse gathers the equipment and prepares the newborn

Figure 33-88 » Circumcision using a circumcision clamp. **A**, The prepuce is drawn over the cone and **B**, the clamp is applied. Pressure is maintained for 3–4 minutes, and then excess prepuce is cut away.

by removing the diaper and placing him on a padded circumcision board or some other type of restraint, but with only the legs restrained. These restraint measures, along with the application of warm blankets to the upper body, increase the newborn's comfort during the procedure. In Jewish circumcision ceremonies, the newborn is held by the father or godfather and is given wine before the procedure.

Various devices (Gomco clamp, Plastibell, and Mogen clamp) are used for circumcision (**Figures 33-88** » and **33-89** »), and all produce a small amount of bleeding. Therefore, the nurse should make special note of neonates with a family history of bleeding disorders or with mothers who took anticoagulants, including aspirin, prenatally. During the procedure, the nurse assesses the newborn's response. One important consideration is pain experienced by the newborn. A dorsal penile nerve block or ring block using 1% lidocaine without epinephrine or similar anesthetic significantly minimizes the pain and shifts in behavioral patterns, such as crying, irritability, and erratic sleep cycles, that are associated with circumcision. Other studies

Figure 33-89 » Circumcision using the Plastibell. The bell is fitted over the glans. A suture is tied around the bell's rim, and the excess prepuce is cut away. The plastic rim remains in place for 3–4 days until healing occurs. The bell may be allowed to fall off; it is removed if still in place after 8 days.

are investigating the use of topical anesthetic applied 60–90 minutes before prepuce removal, acetaminophen, and cryoanalgesia. Studies indicate that a combination of methods is most effective in reducing pain during circumcision (AAP & ACOG, 2012). As indicated in Evidence-Based Practice: Breastfeeding to Control Procedural Pain in Newborns, a common method used to control pain associated with circumcision offers an opportunity for the mother to provide comfort for her newborn while diminishing anxiety related to concern about the procedure.

Following the circumcision, the newborn should be held and comforted by a family member or the nurse. The nurse must be alert to any behavioral cues that these measures are overstimulating the newborn instead of comforting him. Such cues include turning away of the head, increased generalized body movement, skin color changes, hyperalertness, and hiccoughing.

Ideally, the circumcision should be assessed every 30 minutes for at least 2 hours following the procedure. It is important to observe for the first voiding after a circumcision in order to evaluate for urinary obstruction related to penile injury and/or edema. Petroleum ointment and gauze may be applied to the site immediately following the procedure to help prevent bleeding and can be used to protect the healing tissue afterward.

The nurse must also teach family members how to assess for unusual bleeding, how to respond if unusual bleeding is present, and how to care for the newly circumcised penis. Parents of babies circumcised with a method other than the Plastibell should receive the following information:

- Clean the site with warm water with each diaper change.
- Apply petroleum ointment for the next few diaper changes to help prevent further bleeding.

Evidence-Based Practice

Breastfeeding to Control Procedural Pain in Newborns

Problem

What nonpharmacologic methods can help reduce the pain associated with common neonatal procedures?

Evidence

Assessment and management of pain are important issues in neonatal care. Most newborns will experience a venipuncture or heel lance for blood sampling during their hospital stay. Although health-care providers agree that newborns are capable of responding to painful stimuli, most providers do not administer medication to control the short-term pain associated with these common procedures. A Cochrane systematic review investigated the use of breastfeeding—specifically, the oral administration of breast milk—to control the pain associated with common procedures (Harrison et al., 2016). Multiple systematic reviews with this quantity of randomized trials represent the strongest level of evidence for nursing practice.

Newborns who were feeding during heelsticks or venipuncture procedures demonstrated fewer physiologic and behavioral signs of pain. Actual feeding at the breast was associated with a reduction in heart rate change, percentage time crying, duration of crying, and improvement in validated neonatal pain measures. Breastfeeding led to significantly lower increases in heart rate and decreased crying time compared to those who were swaddled. All groups that were fed during the procedure—whether it was breast milk from the mother or expressed breast milk—had better pain control than babies who were swaddled, positioned, or given a pacifier without being held.

Implications

It does not appear that any of these measures completely eliminated the pain of routine procedures. In addition, these studies were focused on healthy newborns undergoing minimally invasive, singular painful procedures. The effectiveness of either breast milk for repeated painful procedures was not studied. With regard to preterm or sick newborns, there is insufficient evidence to support the safety of breast milk or sucrose as a routine, repeated comfort measure. For preterm and sick full-term newborns who are subjected to repeated painful procedures during hospitalization, the ideal analgesic has not yet been identified.

Newborns undergoing single painful procedures, such as venipuncture or heelstick, should be breastfed by the mother during the procedure if at all possible. If not, the baby can be fed expressed breast milk with a syringe, a bottle, or by dipping a pacifier in the solution. Holding the baby while doing so achieves the best pain control.

Critical Thinking Application

1. What are the challenges with breastfeeding to control procedural pain in newborns?
2. How could we measure the influence of breastfeeding on newborn pain during procedures?

- If bleeding does occur, apply light pressure with a sterile gauze pad to stop the bleeding within a short time. If this is not effective, contact the physician immediately, or take the baby to the caregiver's office.
- The glans normally has granulation tissue (a yellowish film) on it during healing. Continued application of a petroleum ointment (or ointment suggested by the healthcare provider) can help protect the granulation tissue that forms as the glans heals.
- Report to the care provider any signs or symptoms of infection, such as increasing swelling, pus drainage, and cessation of urination.
- When diapering, ensure that the diaper is not loose enough to cause rubbing with movement and is not tight enough to cause pain.
- If the newborn's care provider recommends oral analgesics, follow instructions for proper measuring and administration.

If the Plastibell is used, parents should receive information about normal appearance and how to observe for infection. The parents are informed that the Plastibell should fall off within 8 days. If it remains on after 8 days, they should consult with their physician. No ointments or creams should be used while the bell remains, but application of petroleum ointment may protect granulation tissue afterward.

STRENGTHENING PARENT-NEWBORN ATTACHMENT The nurse encourages parent-newborn attachment by involving all family members with the new member of

the family. The nurse can discuss waking activities, such as talking with the baby while making eye contact, holding the baby in an upright position (sitting or standing), gently bending the baby back and forth while grasping under the knees and supporting the head and back with the other hand, or gently rubbing the baby's hands and feet. Quieting activities may include swaddling or bundling the baby to increase a sense of security; using slow, calming movements; and talking softly, singing, or humming to the baby. See Focus on Integrative Health: Baby Massage.

When fostering parent-newborn attachment, it is important to be sensitive to the cultural beliefs and values of the family. The nurse must also be aware of cultural variations in newborn care (see Focus on Diversity and Culture:

Focus on Integrative Health Baby Massage

Massage is a common child care practice in many parts of the world, especially Africa and Asia, that has recently gained attention in the United States. The nurse can teach parents to use massage as a method to facilitate the bonding process and to reduce the stress and pain associated with teething, constipation, inoculations, and colic. Massage not only induces relaxation for the baby, it also provides a calming and "feel-good" interaction for the parents that fosters the development of warm, positive relationships.

Focus on Diversity and Culture

Islamic Birth Traditions

At the birth of a child, Muslim families may follow one or more of several Islamic practices, a few of which are described here.

- The pregnant woman may choose to have only women attending at the birth of the baby. Note that Islam allows male providers to care for pregnant women. The father may attend the birth; Islam does not prohibit it.
- The father or an elder will speak the first words the newborn hears by whispering into the child's ear. These words are the *Adhan*, or *adhaan*, a call to prayer performed five times a day. By these words, the newborn is welcomed to a prayerful life, to Islam, and to the Muslim community.
- Within the child's first seven days, the parents may choose to circumcise the child, often doing so before leaving the hospital. Also during this first week, the parents will give the child a Muslim name.

Prepare Family for Discharge

Although the adjustment to parenting is a normal process, going home presents a critical transition for the family. The parents become the primary caregivers for the newborn and must provide a nurturing environment in which the emotional and physical needs of the newborn can be met. Nursing interventions focus on promoting health and preventing possible problems.

PARENT TEACHING Nearly every contact with the parents presents an opportunity for sharing information that can facilitate their sense of competence in newborn care. To meet the parents' need for information, the nurse who is responsible for the care of the mother and newborn should assume the primary responsibility for parent education. The nurse should teach the family all necessary caregiving methods before discharge. A checklist may be helpful to determine whether the teaching has been completed and to verify the parents' knowledge on leaving the birthing unit (**Figure 33-90** »). The nurse needs to review all areas for understanding by the mother and father, without rushing, and then take the time to resolve all of their queries. Any concerns of the parents or nurse are noted. Unless their care methods are harmful to the newborn, the parents' methods of giving care should be reinforced rather than contradicted.

Caring for newborns in the hospital setting means that the nurse will have contact with patients from a wide variety of ethnic, religious, and cultural backgrounds. The nurse needs to recognize and respect the many good ways of providing safe care and must be sensitive to the cultural beliefs and values of the family. Although it may not be possible to be conversant with all cultures, the nurse can demonstrate

cultural sensitivity with both colleagues and patients as follows (Spector, 2017):

- Show respect for the inherent dignity of every human being, whatever the individual's age, gender, or religion.
- Accept the rights of individuals to choose their care provider, participate in care, and refuse care.
- Acknowledge personal biases, and prevent them from interfering with the delivery of quality care to individuals of other cultures.
- Recognize cultural issues, and interact with patients from other cultures in culturally sensitive ways.
- Incorporate the patient's cultural preferences, health beliefs and behaviors, and traditional practices into the plan of care.
- Develop appropriate educational materials that address the language and cultural beliefs of the patient.
- Access culturally appropriate resources to deliver care to patients from other cultures.
- Assist patients to access high-quality care within a dominant culture.

Parents may be familiar with handling and caring for babies, or this may be their first time interacting with a newborn. If they are new parents, the sensitive nurse gently teaches them by example and provides instructions geared to their needs and previous knowledge about the various aspects of newborn care.

The length of stay in the birthing unit for mother and baby after birth is often 72 hours or less. The challenge for the nurse is to use every opportunity to teach, guide, and support individual parents, fostering their capabilities and confidence in caring for their newborn. Including mother-baby care and home care instruction on the night shift assists with education needs for early-discharge parents.

The nurse observes how parents interact with their newborn during feeding and caregiving activities. Even during a short stay, the nurse will have opportunities to provide information and observe whether the parents are comfortable with changing the diapers of, wrapping, handling, and feeding their newborn. Do both parents get involved in the newborn's care? Is the mother depending on someone else to help her at home? Does the mother give reasons (e.g., "I'm too tired," "My stitches hurt," or "I'll learn later") for not wanting to be involved in her baby's care? As the family provides care, the nurse can enhance parental confidence by giving them positive feedback. If the parents encounter problems, the nurse can express confidence in their abilities to master the new skills or information, suggest alternatives, and serve as a role model. All of these factors need to be considered when evaluating the educational needs of the parents. In addition to the learning needs of parents, cultural factors must also be considered when providing patient education. As noted in Focus on Diversity and Culture: Examples of Cultural Beliefs and Practices Regarding Baby Care, parents from different cultures have differing views on subjects such as umbilical cord care, parent-newborn contact, feeding, circumcision, and health and illness.

Several methods may be used to teach families about newborn care. Daily newborn care videos and classes are

nonthreatening ways to convey general information. Individual instruction is helpful to answer specific questions or to clarify an item that may have been confusing in class. Currently, many birthing centers have 24-hour educational video channels or videos to be viewed in the mother's room on a variety of postpartum and newborn care issues.

One-to-one teaching while the nurse is in the mother's room is the most effective educational method. Individual instruction is helpful both to answer specific questions and to clarify something that the parents may have found confusing in the educational video. With shorter stays, most teaching unfortunately tends to focus on newborn feeding and immediate physical care needs of the mothers, with limited anticipatory guidance provided in other areas.

» Go to **Pearson MyLab Nursing and eText** to see Chart 19: What to Tell Parents About Newborn Care.

GENERAL INSTRUCTIONS FOR NEWBORN CARE One of the first concerns of anyone who has not had the experience of picking up a baby is how to do it correctly. The newborn is easily picked up by sliding one hand under the neck and shoulders and the other hand under the buttocks or between the newborn's legs and then gently lifting upward. This technique provides security and support for the head, which the baby is unable to support until 3 or 4 months of age.

The nurse can be an excellent role model for families in the area of safety. Safety topics include proper positioning of the newborn on the back to sleep and correct use of the bulb syringe (discussed shortly). The baby should never be left alone anywhere but in the crib. The mother is reminded that while she and her newborn are together in the birthing unit, she should never leave her baby alone, both for security reasons and because newborns spit up frequently during the first day or two after birth.

Demonstrating a bath, cord care, and temperature assessment is the best way for the nurse to provide information on these topics to parents. Parents should be told to call their healthcare provider if redness, foul odor, bright-red bleeding, or greenish-yellow drainage occurs at the cord site or if the area remains unhealed 2–3 days after the cord stump has sloughed off. No single method of umbilical cord care (topical antimicrobials [triple dye, iodophor ointment, or hexachlorophene powder] or alcohol) has been proven to be superior in preventing colonization and disease (AAP & ACOG, 2012). The use of sterile water or air drying results in umbilical cords separating more quickly than those treated with alcohol (Fraser, 2014).

NASAL AND ORAL SUCTIONING As mentioned, most newborns are obligatory nose breathers for the first months of life. They generally maintain air passage patency by coughing or sneezing. During the first few days of life, however, the newborn has increased mucus, and gentle suctioning with a bulb syringe may be indicated. The nurse can demonstrate the use of the bulb syringe in the mouth and nose and have the parents do a return demonstration. The parents should repeat this demonstration of suctioning and cleansing the bulb before discharge so that they feel confident in performing the procedure. Care should be taken to apply only gentle suction in order to prevent nasal bleeding.

Focus on Diversity and Culture

Examples of Cultural Beliefs and Practices Regarding Baby Care*

Umbilical Cord

- Individuals of Latin American, Filipino, and Haitian cultural background may use an abdominal binder or bellyband to protect against dirt, injury, and umbilical hernia. They may also apply oils to the stump of the cord or tape metal to the umbilicus to ward off evil spirits (Purnell, 2014).
- Individuals of northern European ancestry may expect a sterile cutting of the cord at birth. They may allow the stump to air dry and discard the cord once it falls off.
- Some Latin American parents cauterize the stump with a candle flame, hot coal, or burning stick.

Parent–Newborn Contact

- Individuals of Asian ancestry may pick up the baby as soon as it cries, or they may carry the baby at all times.
- Individuals of several native North American nations, notably the Navajos, may use cradle boards so that the baby can be with family even during work and feel secure (Woodring & Andrews, 2012).
- The Muslim father traditionally calls praise to Allah in the newborn's right ear and cleans the baby after birth (Purnell, 2014).

Feeding

- Some women of Asian heritage may breastfeed their babies for the first 1–2 years of life. Many Cambodian refugees practice breastfeeding on demand without restriction or, if formula feeding, provide a “comfort bottle” in between feedings.
- Individuals of Iranian heritage may breastfeed female babies longer than male babies. Many Muslim women will not breastfeed in public.
- Some individuals of African ancestry may wean their babies after they begin to walk.

*Note: This information is meant only to provide examples of the behaviors that may be found within certain cultures. Not all members of a culture practice the behaviors described.

- Some Asians, Haitian, Hispanics, Eastern Europeans, and Native Americans may delay breastfeeding because they believe colostrum is “bad.”
- Haitian mothers may believe that “strong emotions” spoil breast milk.

Circumcision

- Individuals of Muslim and Jewish ancestry practice circumcision as a religious ritual (Purnell, 2014).
- Many natives of Africa and Australia practice circumcision as a puberty rite.
- Native Americans and individuals of Asian and Latin American cultures rarely perform circumcision.
- As of 2015, an estimated 38.7% of males worldwide were circumcised (Morris et al., 2016).

Health and Illness

- Some individuals with Latin American cultural backgrounds may believe that touching the face or head of a baby when admiring it will ward off the “evil eye.” They may also neglect to cut the baby's nails to avoid nearsightedness and, instead, put mittens on the baby's hands to prevent scratching. They also may believe that fat babies are healthy (Woodring & Andrews, 2012).
- Some individuals of Asian heritage may not allow anyone to touch the baby's head without asking permission.
- Some Orthodox Jews believe that saying the baby's name before the formal naming ceremony will harm the baby.
- Some Asians and Haitians delay naming their babies until after confinement month (Purnell, 2014).
- Some individuals of Vietnamese ancestry believe that cutting a baby's hair or nails will cause illness.

To suction the newborn, the bulb syringe is compressed before the tip is placed in the nostril. The nurse or parent must take care not to occlude the passageway. The bulb is permitted to reexpand slowly by releasing the compression on the bulb. The bulb syringe is removed from the nostril, and drainage is then compressed out of the bulb and onto a tissue. The bulb syringe may also be used in the mouth if the newborn is spitting up and unable to handle the excess secretions. The bulb is compressed, the tip of the bulb syringe is placed approximately 2.5 cm (1 in.) to one side of the newborn's mouth, and compression is released. This draws up the excess secretions. The procedure is repeated on the other side of the mouth. The roof of the mouth and the back of the throat are avoided, because suction in these areas might stimulate the gag reflex. The bulb syringe should be washed in warm, soapy water and rinsed in warm water daily and as needed after use. Rinsing with a half-strength white vinegar solution followed by clear water may help to extend the useful life of the bulb syringe by inhibiting bacterial growth. A bulb syringe should always be kept near the newborn. New parents and nurses who are inexperienced with babies may fear that

the baby will choke and are relieved to know how to take action if such an event occurs. They should be advised to turn the newborn's head to the side or hold the newborn with his or her head down as soon as there is any indication of gagging or vomiting and to use the bulb syringe as needed.

Some newborns may have transient edema of the nasal mucosa following suctioning of the airway after birth. The nurse can demonstrate the use of normal saline to loosen secretions and instruct parents in the gentle and moderate use of the bulb syringe to avoid further irritation of the mucous membranes. If parents will be using humidifiers at home, they should be instructed to follow the manufacturer's cleaning instructions carefully so that molds, spores, and bacteria from a dirty humidifier do not enter the baby's environment.

SWADDLING THE NEWBORN Swaddling (wrapping) helps the newborn maintain body temperature, provides a feeling of closeness and security, and may be effective in quieting a crying baby by having the newborn's hands near his or her mouth to allow sucking (Young et al., 2013). A

Figure 33-91 » Steps in wrapping a baby.

blanket is placed on the crib (or secure surface) in the shape of a diamond. The top corner of the blanket is folded down slightly, and the newborn's body is placed with the head at the upper edge of the blanket. The right corner of the blanket is wrapped around the newborn and tucked under the left side (not too tightly—the newborn needs a little room to move and to allow for hands to get to the mouth). The bottom corner is then pulled up to the chest, and the left corner is wrapped around the baby's right side (**Figure 33-91** »). The nurse can show this wrapping technique to new parents so that they will feel more skilled in handling their baby.

SLEEP AND ACTIVITY The National Institute of Child Health and Human Development and the AAP recommend that healthy term newborns be placed on their backs to sleep (**Figure 33-92** »). Parents are taught the importance of

Source: Michele Davidson.

Figure 33-92 » Babies should be placed on their backs when sleeping.

following “Safe to Sleep Guidelines” to reduce the incidence of sudden infant death syndrome (SIDS) (Healthy Children, 2015a). Though neonates may need to be placed on their sides initially because of copious or thick secretions, placing them on their backs in the newborn period serves to educate parents regarding safe sleep positioning. Studies indicate that parents position their babies in the same positions they observe in the hospital setting, so the nurse must demonstrate this behavior to reduce the risk of SIDS. If exceptions are warranted, these should be explained to families so that they do not misinterpret what they observe. The placement of babies in a prone position during wakeful play sessions (“tummy time”) should be encouraged as well (AAP & ACOG, 2012). See the exemplar on Sudden Infant Death Syndrome, in the module on Oxygenation, for more information.

» **Stay Current:** Visit the Safe to Sleep website at <https://www.nichd.nih.gov/sts/Pages/default.aspx> to learn current recommendations for safe sleeping.

Perhaps nothing is more individual to each baby than the sleep–activity cycle. It is important for the nurse to recognize the individual variations of each newborn and to assist parents as they develop sensitivity to their baby's communication signals and rhythms of activity and sleep.

CAR SAFETY CONSIDERATIONS Half of the children killed or injured in automobile crashes could have been protected by the use of federally approved car seats. Newborns must go home from the birthing unit in a car seat adapted to fit them. Babies should never be placed in the front seat of a car equipped with a passenger-side airbag. The car seat should be positioned to face the rear of the car until the baby is 2 years old or until the child reaches the maximum height and weight for the seat (Healthy Children, 2015b). The nurse needs to ensure that all parents are knowledgeable about the proper installation and benefits of using a child safety seat. The nurse can encourage parents to have their safety seats checked by local groups trained specifically for that purpose. The Seat Check Initiative provides locations and information about child safety seats.

» **Stay Current:** Visit <http://www.safercar.gov/parents/index.htm> to learn how to install car seats properly and about occupant protection laws in each state.

NEWBORN SCREENING AND IMMUNIZATION PROGRAMS Before the newborn and mother are discharged from the birthing unit, the nurse informs the parents about the newborn screening tests and tells them when to return to the birthing center or clinic if further tests are needed. Some of the disorders that can be identified from a few drops of blood obtained by a heelstick are cystic fibrosis (see the exemplar on Cystic Fibrosis in the module on Oxygenation), galactosemia, congenital adrenal hyperplasia, congenital hypothyroidism, maple syrup urine disease, PKU, sickle cell trait (see the exemplar on Sickle Cell Disease in the module on Cellular Regulation), biotinidase deficiency, and hemoglobinopathies.

Early discharge has affected both the timing of newborn metabolic screening tests and the acquisition of subsequent immunization. Early newborn discharge increases the risk for a delayed or even missed diagnosis of PKU and congenital

hypothyroidism because of decreased sensitivity of screening before 24 hours of age. Newborns should be retested by 2 weeks of age if the first test was done before 24 hours of age. A second test for PKU is required in most states, usually between 1 week and 1 month of age, to minimize the chance of a child with PKU going undetected.

New technology is quickly increasing the number of metabolic and other disorders that can be detected in the newborn period. The March of Dimes (2012) recommends newborn screening tests for 31 health conditions. In most states, newborn screening programs lead to the detection of several conditions before symptoms develop. While all states require screening for more than 50 congenital conditions, each state decides on the number and type of conditions (CDC, 2014b).

Hearing loss is found in 1 to 3 per 1000 babies in the normal newborn population (CDC, 2015c). Hearing screenings before discharge are now conducted in all 50 states. The recommended initial newborn hearing screening should be accomplished before discharge from the birthing unit with appropriate follow-up if the newborn fails to pass the initial screen in all hospitals providing obstetric services (**Figure 33–93** ▶).

Sometimes, newborns fail to pass these tests for reasons other than hearing loss. Amniotic fluid in the ear canals is a frequent cause of suboptimal test results. In these cases, babies are retested in a week or two. The current goal is to screen all babies by 1 month of age, confirm hearing loss with audiologic examination by 3 months of age, and treat with comprehensive early intervention services (CDC, 2015c). Typically, screening programs use a two-stage screening approach (autoacoustic emissions [OAE] repeated twice, OAE followed by auditory brain stem response [ABR], or automated ABR repeated twice). Families need to be educated about appropriate interpretation of screening test results and appropriate steps for follow-up (Healthy Children, 2015c).

Immunization programs against the hepatitis B virus during the newborn period and infancy are in place in many U.S. states, in at least 20 countries, and in high-incidence areas

such as American Samoa. Universal vaccination of newborns and infants is recommended. Babies should receive the first dose of hepatitis B vaccine during the period from birth to 2 months of age. The second dose should be administered at least 1 month after the first dose. The third dose should be administered at least 4 months after the first dose and at least 2 months after the second dose, but not before 6 months of age (AAP & ACOG, 2012). Parents need to be advised whether their birthing center provides newborn hepatitis vaccination so that an adequate follow-up program can be set in motion.

▶ **Stay Current:** Find up-to-date immunization schedules for children from birth to 6 years in English and Spanish at the CDC website at www.cdc.gov/vaccines/schedules/easy-to-read/child.html

COMMUNITY-BASED NURSING CARE The nurse should discuss with parents ways to meet their newborn's needs, ensure safety, and appreciate the newborn's unique characteristics and behaviors. By assisting parents in establishing links with their community-based healthcare provider, the nurse can get the new family off to a good start.

Key topics for parent education include:

- Knowing signs of illness and when to call the pediatrician
- Contact information for the pediatrician and nursery unit
- How to reach the pediatrician after hours
- Follow-up care after discharge
- Use of OTC medications and safety
- Importance of routine well-baby visits.

Some institutions have initiated postpartum and/or newborn follow-up home visits, especially for newborns discharged before 48 hours after birth. The follow-up home examination should be within 48 hours of discharge (AAP & ACOG, 2012) when the family is unable to visit their primary care physician within that time period. The home visit focuses on normal newborn care, assessment for hyperbilirubinemia (jaundice), extreme weight loss, feeding problems, and knowledge related to newborn care and feeding within the family unit.

Evaluation

When evaluating the nursing care provided during the period immediately after birth, the nurse may anticipate the following outcomes:

- The newborn's adaptation to extrauterine life is successful, as demonstrated by all vital signs being within acceptable parameters.
- The newborn's physiologic and psychologic integrity is supported.
- Positive interactions between parent and newborn are supported.

When evaluating the nursing care provided during the newborn period, the nurse may anticipate the following outcomes:

- The newborn's physiologic and psychologic integrity is supported by maintaining stable vital signs and interactions based on normal newborn behaviors.
- The newborn feeding pattern has been satisfactorily established.

Source: Vanessa Howell, RN, MSN.

Figure 33–93 ▶ Newborn hearing screen.

- The parents express understanding of the bonding process and display attachment behaviors.

When evaluating the nursing care provided in preparation for discharge, the nurse may anticipate the following outcomes:

- The parents demonstrate safe techniques in caring for their newborn.
- Parents verbalize developmentally appropriate behavioral expectations of their newborn and knowledge of community-based newborn follow-up care.

Conducting additional care evaluation determines if further care is needed based on newborn outcomes. If the

outcomes are not met, the nurse may choose to continue or revise the plan of care for optimal outcome attainment. Continuation, revision, or discontinuation of a plan of care is decided through the collaboration of all members of the healthcare team.

As noted in the Nursing Care Plan: A Small-for-Gestational-Age Newborn, focused assessments include weight, thermoregulation, perfusion, and metabolism. Because these concepts are closely interrelated, an alteration in one may lead to alterations in others. Accurate assessment and identification of priority diagnoses allows for prompt intervention and improved patient outcomes.

Nursing Care Plan

A Small-for-Gestational-Age Newborn

Ellen, a term baby, was born 8 hours ago weighing 2500 g at 40 weeks of gestation. Two hours after birth, Ellen's temperature was 37.1°C (98.8°F) under the radiant warmer. She was swaddled and placed in an open crib. One hour later, Ellen is returned to the

radiant warmer with a falling temperature reading of 36.1°C (97°F). Acrocyanosis has also been detected. The glucose level is 35 mg/dL. The nurse monitors the newborn for signs of hypothermia and hypoglycemia.

ASSESSMENT	DIAGNOSES	PLANNING
<p>Subjective: Alert and active.</p> <p>Objective: 40 weeks of gestation; birth weight, 2500 g; length, 48.3 cm (19 in.); head circumference, 30 cm (11.8 in.); chest circumference, 28 cm (11 in.); temperature, 36.1°C (97°F) axillary; pulse, 140 beats/min; respirations, 45 breaths/min; vigorous cry, alert, and wide-eyed; dry skin; thin, meconium-stained umbilical cord; glucose, 35 mg/dL; and tremors.</p>	<ul style="list-style-type: none"> ■ <i>Hypothermia</i> related to decrease in subcutaneous fat tissue and increased body surface exposure to environment ■ <i>Imbalanced Nutrition: Less Than Body Requirements</i> related to increased glucose consumption secondary to metabolic effects of hypothermia and poor hepatic glycogen stores ■ <i>Risk for Injury</i> related to hypoglycemia secondary to the metabolic effects of hypothermia and poor hepatic glycogen stores <p>(NANDA-I © 2014)</p>	<ul style="list-style-type: none"> ■ The newborn will maintain stable body temperature within normal range of 36.5°–37.4°C (97.7°–99.4°F) in an open crib. ■ The newborn will not exhibit signs of acrocyanosis, mottling, or lethargy. ■ The newborn will maintain a glucose level above 40 mg/dL. ■ The newborn's weight will remain stable. ■ The newborn will not exhibit any unusual jitteriness or tremors.

IMPLEMENTATION

- | | |
|---|--|
| <ul style="list-style-type: none"> ■ Monitor axillary temperature every 4 hours and prn. ■ Monitor pulse and respirations every 4 hours and prn. ■ Assess skin color and temperature every 15–30 minutes in presence of color change. ■ Place newborn skin-to-skin with mother for mild hypothermia if the baby is stable and the parent is willing. If ineffective, place newborn under radiant warmer if temperature falls below 36.5°C (97.7°F). ■ Place newborn in incubator if temperature is unstable. | <ul style="list-style-type: none"> ■ Initiate frequent feeding as tolerated (10 mL/kg is a general guideline for formula feeding). ■ Initiate early feedings. ■ Monitor glucose levels every 4 hours. ■ Monitor for signs of hypoglycemia. ■ Encourage on-demand feeding at least every 3–4 hours. ■ Offer supplemental feedings or additional glucose. ■ Maintain a neutral thermal environment. |
|---|--|

EVALUATION

- | | |
|---|---|
| <ul style="list-style-type: none"> ■ The newborn's temperature remains between 36.5° and 37.4°C (97.7° and 99.4°F) in an open crib. ■ The skin is pink in color, with no signs of acrocyanosis or mottling. | <ul style="list-style-type: none"> ■ The glucose level remains above 45 mg/dL. ■ The newborn's weight is stabilized. ■ No signs of jitteriness or tremors are present. |
|---|---|

CRITICAL THINKING

1. What can the nurse do to prevent heat loss through convection when preparing the newborn for the open crib?
2. What measure can the nurse take to reduce heat loss through evaporation and conduction? How many calories can a SGA newborn lose through radiation?
3. Parents of an SGA newborn ask the nurse when they should expect their baby to catch up in weight to normal-growth newborns. What is the nurse's best response?

REVIEW Newborn Care

RELATE Link the Concepts and Exemplars

Linking the exemplar of newborn care with the concept of stress and coping:

1. What stressors does a newborn place on the family?
2. What assessment findings might you anticipate in a family that is not coping appropriately with the stress brought on by caring for their newborn? What actions might the nurse take to improve coping strategies?

Linking the exemplar of newborn care with the concept of immunity:

3. What recommendations would you make to the parents during discharge teaching related to their newborn's immune system?
4. While planning for discharge from the hospital, the mother of a newborn asks you, "What vaccinations does my baby need first?" How would you respond to this question?

REFLECT Apply Your Knowledge

Maria and Carlos Ramirez are preparing to take their newborn daughter home. They have three other daughters at home, ages 7 years, 3 years, and 2 years. Mrs. Ramirez tells you that the middle child was very jealous when she brought the 2-year-old home from the hospital and is worried about how the children will respond to this new baby.

1. Mrs. Ramirez says she would like to breastfeed the baby, but wonders if that will increase the sibling rivalry among her other children. How would you respond to this concern?
2. What strategies might you recommend to Mrs. Ramirez to reduce sibling rivalry when introducing the new baby to the family?
3. Mr. Ramirez shares with you, while Mrs. Ramirez is out of the room, that he had really hoped this new baby would be a boy. What assessment questions might you ask of this father?

Exemplar 33.E Prematurity

Exemplar Learning Outcomes

33.E Summarize care of premature newborns.

- Describe the physiology and risk factors of the premature newborn.
- Summarize alterations found in premature newborns.
- Describe the nursing process in assessing the premature newborn and implementing culturally competent care to the baby and the family.

Overview

A **preterm newborn** is a baby born at less than 37 completed weeks of gestation (ACOG & Society for Maternal-Fetal Medicine [SMFM], 2013, reaffirmed 2015; Spong, 2013). The incidence of all preterm births in the United States is approximately 10% (CDC, 2015d). With the help of modern technology, neonates are surviving at younger gestational ages, but not without significant morbidity. The rise in multiple birth rates has markedly influenced overall rates of low-birth-weight neonates. **Figure 33-94** » shows a comparison of a premature neonate, a low-birth-weight neonate, and a full-term neonate.

The Preterm Newborn

The major problem of the preterm newborn is the variable immaturity of all systems. The degree of immaturity depends on the length of gestation. The preterm newborn

Exemplar Key Terms

Apnea of prematurity, 2413
Minimal enteral nutrition, 2412
Preterm newborn, 2408

Figure 33-94 » From left to right: A 4-week-old neonate who was born 9 weeks premature, a 2-week-old neonate who weighed 1200 g at birth, and a full-term neonate, 2 days old, who weighed 3730 g at birth.

must traverse the same complex, interconnected pathways from intrauterine to extrauterine life as the term newborn. Because of immaturity, however, the premature newborn is ill equipped to make this transition smoothly. Maintenance of the preterm newborn falls within narrow physiologic parameters.

Respiratory and Cardiac Physiology

The preterm newborn is at risk for respiratory problems because the lungs are not fully mature and not fully ready to take over the process of oxygen and carbon dioxide exchange without assistance. Critical factors in the development of respiratory distress include the following:

- **The preterm neonate is unable to produce adequate amounts of surfactant.** Inadequate surfactant lessens compliance (ability of the lung to fill with air easily), thereby increasing the inspiratory pressure needed to expand the lungs with air. The collapsed (or atelectatic) alveoli will not facilitate an exchange of oxygen and carbon dioxide. As a result, the neonate becomes hypoxic, pulmonary blood flow is inefficient, and the preterm newborn's available energy is depleted.
- **The muscular coat of pulmonary blood vessels is incompletely developed.** As a result, the pulmonary arterioles do not constrict well in response to decreased oxygen levels. This lowered pulmonary vascular resistance leads to left-to-right shunting of blood through the ductus arteriosus, which increases the blood flow back into the lungs.
- **The ductus arteriosus of the preterm neonate, who is more susceptible to hypoxia, may respond to increasing oxygen and prostaglandin E levels by remaining open rather than by vasoconstriction, which is how the ductus responds in the term neonate.** A patent ductus increases the blood volume to the lungs, causing pulmonary congestion, increased respiratory effort, carbon dioxide retention, and bounding femoral pulses.

Thermoregulation

Heat loss is a major problem in premature newborns. Two factors limiting heat production are the availability of glycogen in the liver and the amount of brown fat available for heat production. Both of these limiting factors appear in the third trimester. In the cold-stressed baby, norepinephrine is released, which in turn stimulates the metabolism of brown fat for heat production. As a complicating factor, the hypoxic newborn cannot increase oxygen consumption in response to cold stress because of the already limited reserves; as a result, the hypoxic newborn becomes progressively colder. Preterm neonates have smaller muscle mass and diminished muscular activity, rendering them unable to shiver and further limiting heat production.

There are five physiologic and anatomic factors that increase heat loss in the preterm neonate.

1. **The preterm newborn has a higher ratio of body surface to body weight.** This means that the baby's ability to produce heat (based on body weight) is much less than the potential for losing heat (based on surface area). The loss of heat in a preterm neonate weighing

1500 g is five times greater per unit of body weight than that of an adult.

2. **The preterm newborn has very little subcutaneous fat, which is the human body's insulation.** Without adequate insulation, heat is easily conducted from the core of the body (warmer temperature) to the surface of the body (cooler temperature). Heat is lost from the body as the blood vessels, which lie close to the skin surface in the preterm neonate, transport blood from the body core to the subcutaneous tissues.
3. **The preterm newborn has thinner, more permeable skin than the term neonate.** This increased permeability contributes to a greater insensible water loss as well as to heat loss.
4. **The posture of the preterm newborn influences heat loss.** Flexion of the extremities decreases the amount of surface area exposed to the environment. Extension increases the surface area exposed to the environment and thus increases heat loss. The gestational age of the neonate influences the amount of flexion, from completely hypotonic and extended at 28 weeks to stronger flexion at 35 weeks and full flexion of all extremities at term (see Resting posture in Figure 33–69).
5. **The premature newborn has a decreased ability to vasoconstrict superficial blood vessels and conserve heat in the body core.** This lack of vasoconstriction allows heat to leave the premature neonate's body at a fast rate, thus leading to cold stress.

Thermoregulation is discussed more completely in the module on Thermoregulation. The essential point regarding thermoregulation of the premature neonate, however, is this: Gestational age is directly proportional to the ability to maintain thermoregulation; thus, the more preterm the newborn, the less able the neonate is to maintain heat balance.

The nurse can do much to prevent heat loss by providing a neutral thermal environment. This is one of the most important considerations in nursing management of the preterm neonate (see Maintain a Neutral Thermal Environment section later in this exemplar). Cold stress, with its accompanying severe complications, can be prevented.

Gastrointestinal Physiology

The basic structure of the gastrointestinal (GI) tract is formed early in gestation. The maturation of the digestive and absorptive process is more variable, however, and occurs later in gestation. As a result of GI immaturity, the preterm newborn has the following ingestion, digestive, and absorption problems:

- A marked danger of aspiration and its associated complications because of the premature neonate's poorly developed gag reflex, incompetent esophageal cardiac sphincter, and poor sucking and swallowing reflexes. The ability to coordinate sucking, swallow, and breathing is not established until 32–34 weeks' gestation.
- Difficulty in meeting high caloric and fluid needs for growth because of small stomach capacity.

- Limited ability to convert certain essential amino acids to nonessential amino acids. Some amino acids, such as histidine, taurine, and cysteine, are essential to the preterm neonate but not to the term neonate.
- Inability to handle the increased osmolarity of formula protein because of kidney immaturity. The preterm neonate requires a higher concentration of whey protein than of casein.
- Difficulty absorbing saturated fats because of decreased bile salts and pancreatic lipase. Severe illness of the newborn may also prevent intake of adequate nutrients.
- Initial difficulty with lactose digestion because processes may not be fully functional during the first few days of a preterm neonate's life. The preterm newborn can digest and absorb most simple sugars.
- Deficiency of calcium and phosphorus may exist because two thirds of these minerals are deposited in the last trimester. This can lead to rickets and significant bone demineralization.
- Increased basal metabolic rate and increased oxygen requirements caused by fatigue associated with sucking.
- Feeding intolerance and necrotizing enterocolitis (NEC) as a result of diminished blood flow and tissue perfusion to the intestinal tract because of prolonged hypoxia and hypoxemia at birth.

Renal Physiology

The kidneys of the premature neonate are immature compared with those of the full-term neonate, posing clinical problems in the management of fluid and electrolyte balance. Specific renal characteristics of the preterm neonate include the following:

- The glomerular filtration rate (GFR) is lower because of decreased renal blood flow. The GFR is directly related to lower gestational age, so the more preterm the newborn, the lower the GFR. The GFR is also decreased in the presence of diseases or conditions that decrease renal blood flow and perfusion, such as severe respiratory distress, hypotension, and asphyxia. Anuria and oliguria may also be observed.
- The preterm neonate's kidneys are limited in their ability to concentrate urine or to excrete excess amounts of fluid. This means that if excess fluid is administered, the neonate is at risk for fluid retention and overhydration. If too little fluid is administered, the neonate will become dehydrated because of the inability to retain adequate fluid.
- The kidneys of the preterm neonate begin excreting glucose (glycosuria) at a lower serum glucose level than those of the term newborn. Glycosuria with hyperglycemia can lead to osmotic diuresis and polyuria.
- The buffering capacity of the kidney is reduced, predisposing the neonate to metabolic acidosis. Bicarbonate is excreted at a lower serum level, and acid is excreted more slowly. Therefore, after periods of hypoxia or insult, the preterm neonate's kidneys require a longer time to excrete the lactic acid that accumulates. Sodium bicarbonate is frequently required to treat metabolic acidosis in the premature neonate.

- The immaturity of the renal system affects the preterm neonate's ability to excrete drugs. Because excretion time is longer, many drugs are given over longer intervals (i.e., every 24 hours instead of every 12 hours). Urine output must be carefully monitored when the neonate is receiving nephrotoxic drugs, such as gentamicin and vancomycin. If urine output is poor, drugs can become toxic much more quickly in the neonate than in the adult.

Immunologic Physiology

The preterm neonate is at much greater risk for infection than the term neonate. This increased susceptibility may be the result of an infection acquired in utero, which may have precipitated preterm labor and birth. However, all preterm neonates have immature specific and nonspecific immunity.

In utero, the fetus receives passive immunity against a variety of infections from maternal IgG immunoglobulins, which cross the placenta. Because most of this immunity is acquired in the last trimester of pregnancy, the premature neonate has few antibodies at birth, and these antibodies provide less protection and become depleted earlier than in a full-term neonate. The limited number of antibodies in the preterm neonate may be a contributing factor in the higher incidence of recurrent infection during the first year of life as well as in the immediate neonatal period.

The other immunoglobulin that is significant for the preterm neonate is secretory IgA, which does not cross the placenta but is found in breast milk at significant concentrations. The secretory IgA in breast milk provides immunity to the mucosal surfaces of the neonate's GI tract, protecting the baby from enteric infections such as those caused by *Escherichia coli* and *Shigella*.

Another altered defense against infection in the preterm neonate is the skin surface. In very small neonates, the skin is easily excoriated, and this factor, coupled with many invasive procedures, places the neonate at great risk for health-care-associated infections. It is vital to use good hand hygiene in the care of these neonates in order to prevent unnecessary infection.

SAFETY ALERT The sudden onset of apnea and bradycardia, coupled with metabolic acidosis in an otherwise healthy, growing premature neonate, may be suggestive of bacterial sepsis, especially if an invasive device, such as a central line or endotracheal tube, is in place.

Neurologic Physiology

The general shape of the brain is formed during the first 6 weeks of gestation. Between the second and fourth months of gestation, the brain's total complement of neurons proliferates. These neurons migrate to specific sites throughout the central nervous system, and nerve impulse pathways organize. The final step in neurologic development is the covering of these nerves with myelin, which begins in the second trimester of gestation and continues into adult life (Scheibel, 2012).

The period of most rapid brain growth and development occurs during the third trimester of pregnancy; therefore, the closer to term a neonate is born, the better the neurologic prognosis. A common interruption of neurologic development in the preterm neonate is caused by intraventricular

hemorrhage and intracranial hemorrhage. Hydrocephalus may develop as a consequence of an intraventricular hemorrhage caused by the obstruction at the cerebral aqueduct.

Reactivity and Behavioral States

The neonate's response to extrauterine life is characterized by two periods of reactivity. The preterm neonate's periods of reactivity, however, are delayed. In the very ill neonate, these periods of reactivity may not be observed at all, because the neonate may be hypotonic and unreactive for several days after birth.

As the preterm newborn grows and the baby's condition stabilizes, identifying behavioral states and traits unique to each baby becomes increasingly possible. In general, stable preterm neonates do not demonstrate the same behavioral states as term neonates. Preterm neonates tend to be more disorganized in their sleep–wake cycles and are unable to attend as well to the human face and objects in the environment. Neurologically, their responses (sucking, muscle tone, and states of arousal) are weaker than those of full-term neonates.

By observing each neonate's patterns of behavior and responses, especially the sleep–wake states, the parents and nurse can plan nursing care around the times when the neonate is alert and best able to attend. In addition, the more knowledge parents have about the meaning of their newborn's responses and behaviors, the better prepared they will be to meet their newborn's needs and to form a positive attachment with their child. (See the Promote Developmentally Supportive Care section later in this exemplar.)

Nutritional and Fluid Requirements

Beginning feedings as soon as possible is extremely valuable in maintaining normal metabolism and lowering the possibility of such complications as hypoglycemia, hyperbilirubinemia, and azotemia. However, the preterm neonate is at risk for complications that may develop because of immaturity of the digestive system. Advancement of feedings should occur only as the neonate demonstrates tolerance of enteral feedings. Clinical signs of feeding intolerance or illness dictate discontinuing or holding the advancement of feedings.

Nutritional Requirements

Oral (enteral) caloric intake necessary for growth in a healthy preterm newborn is 95–130 kcal/kg per day (Blackburn, 2013). In addition to these relatively high caloric needs, the preterm neonate requires more protein than the full-term neonate. To meet these needs, many institutions use breast milk or special preterm formulas.

Whether breast milk or formula is used, feeding regimens are established on the basis of the neonate's weight and estimated stomach capacity. Initial formula feedings are gradually increased as the neonate tolerates them. It may be necessary to supplement oral feedings with parenteral fluids to maintain adequate hydration and caloric intake until the baby is on full oral feedings. Preterm neonates who cannot tolerate any oral (enteral) feedings are given nutrition by total parenteral nutrition (TPN).

In addition to a higher calorie and protein formula, preterm neonates should receive supplemental multivitamins, including vitamins A, D, and E, as well as iron and trace minerals. A diet high in polyunsaturated fats, which preterm

neonates tolerate best, increases the requirement for vitamin E. Preterm neonates who are fed iron-fortified formulas have higher red cell hemolysis and lower vitamin E concentrations and thus require additional vitamin E. Preterm formulas also need to contain medium-chain triglycerides and additional amino acids, such as cysteine, as well as calcium, phosphorus, and vitamin D supplements to increase mineralization of bones. Rickets and significant bone demineralization have been documented in very-low-birth-weight neonates and otherwise healthy preterm neonates.

Nutritional intake is considered to be adequate when there is consistent weight gain of 20–30 g/day. Initially, no weight gain may be noted for several days, but total weight loss should not exceed 15% of the total birth weight or more than 1–2% per day. Some institutions add the criteria of head circumference growth and increase in body length of 1 cm (0.4 in.) per week once the newborn is stable.

Methods of Feeding

The preterm newborn is fed by various methods, depending on the baby's gestational age, health and physical condition, and neurologic status. The three most common oral feeding methods are bottle, breast, and gavage. In some cases, total parenteral nutrition is used.

BOTTLE FEEDING Preterm neonates who have a coordinated and rhythmic suck–swallow–breathing pattern are usually between 32 and 34 weeks of postconceptual age and may be fed by bottle. Oral readiness to feed is best described by the following engagement and hunger cues: bringing hands to mouth, being alert, exhibiting fussiness, sucking on fingers or pacifier, exhibiting rooting behavior, and showing relaxed facial expression and good tone (Newland, L'Huillier, & Petrey, 2013).

Those premature neonates who root when their cheek is stroked and actively search for the nipple are neurodevelopmentally ready to initiate oral feeding (**Figure 33-95**)).To

Source: Carol Harrigan, RN, MSN, NNP-BC.

Figure 33-95 >> Mother bottle feeding her premature newborn with expressed breast milk.

avoid excessive expenditure of energy, a soft, yellow, single-hole nipple is generally used (milk flow is less rapid). The neonate is fed in a semisitting position and burped gently after each 0.5–1 oz. The feeding should take no longer than 30 minutes (nipples require more energy than other methods). Premature neonates who are progressing from gavage feedings to bottle feeding should start with one session of bottle feeding a day and have the number of times per day a bottle is given slowly increase until the baby tolerates all feedings from a bottle.

In assessing the premature neonate's readiness for feeding, the nurse assesses the neonate's ability to suck. Sucking may be affected by age, asphyxia, sepsis, intraventricular hemorrhage, or other neurologic insult. Before initiating nipple feeding, the nurse observes for signs of stress, such as tachypnea (>60 respirations/min), respiratory distress, or hypothermia, which may increase the risk of aspiration. During the feeding, the nurse observes the neonate for signs of feeding difficulty (tachypnea, cyanosis, bradycardia, lethargy, or uncoordinated suck and swallow). Difficulty in bottle feeding is often associated with a milk bolus that is too large for the neonate's oral cavity, which can lead to aspiration. Demand feeding protocols, based on the neonate's hunger cues, should be considered for a growing premature neonate only when there is sufficient caloric intake to promote consistent weight gain (Newland et al., 2013).

Breastfeeding

Mothers who wish to breastfeed their preterm neonates are given the opportunity to put the baby to the breast as soon as the baby has demonstrated a coordinated suck and swallow reflex, is showing consistent weight gain, and can control body temperature outside of the incubator, regardless of weight. Preterm neonates tolerate breastfeeding with higher transcutaneous oxygen pressures and better maintenance of body temperature than during bottle feeding. Besides breast milk's many benefits for the neonate, breastfeeding allows the mother to contribute actively to the baby's well-being. The nurse should encourage mothers to breastfeed if they choose to do so. It is important for the nurse to be aware of both the advantages of breastfeeding and the possible disadvantages of breast milk as the sole source of food for the preterm neonate. Even if the neonate cannot be put to the breast, mothers can pump breast milk, which can be given via bottle or gavage. Use of the double-pumping system produces higher levels of prolactin than are obtained using sequential pumping of the breasts.

By initiating skin-to-skin holding of premature neonates in the early intensive care phase, mothers can significantly increase milk volume, thereby overcoming lactation problems (Lucas & Smith, 2015). The neonate is placed at the mother's breast. It has been suggested that the football hold is a convenient position for breastfeeding preterm babies. Feeding may take up to 45 minutes, and babies should be burped as they alternate breasts. The length of feeding time is monitored so that the preterm neonate does not burn too many calories.

The nurse should coordinate a flexible feeding schedule so that babies can nurse during alert times and be allowed to set their own pace. Feedings should be on demand, but a maximum number of hours between feedings should be set.

A similar regimen should be used for the baby who is progressing from gavage feeding to breastfeeding. The mother begins with one feeding at the breast and then gradually increases the number of times during the day that the baby breastfeeds. When breastfeeding is not possible because the neonate is too small or too weak to suck at the breast, an option for the mother may be to express her breast milk into a cup. The milk touches the neonate's lips and is lapped by the protruding motions of the tongue.

SAFETY ALERT For an otherwise healthy, growing premature neonate who is receiving total enteral intake and who has started to experience apnea and bradycardia, one differential diagnosis to think about is reflux rather than sepsis, although sepsis may need to be ruled out.

Gavage Feeding

The gavage feeding method is used with preterm neonates (32–34 weeks of gestation) who lack or have a poorly coordinated suck-and-swallow reflex or who are ill and ventilator dependent. Gavage feeding may be used as an adjunct to nipple feeding if the neonate tires easily. It may also be used as an alternative if a neonate is losing weight because of the energy expenditure required for nipple feeding.

Gavage feedings are administered by either the nasogastric or orogastric route and by intermittent bolus or continuous drip method. Bolus feedings may be preferred, because these are thought to be more like normal feedings than the continuous feeding method and may enhance the release of certain GI hormones necessary for development of gastrointestinal tissues (Dawson et al., 2012). Currently, no conclusive studies support one method over the other. In common practice, bolus feedings are usually initiated, but if intolerance occurs, then the feedings are changed to continuous.

Early initiation of **minimal enteral nutrition** via gavage is now advocated as a supplement to parenteral nutrition. Minimal enteral nutrition refers to small-volume feedings of formula or human milk (usually <24 mL/kg per day), which are designed to “prime” the premature neonate's intestinal tract, thereby stimulating many of its hormonal and enzymatic functions (AAP & ACOG, 2012). Benefits of early feeding (as early as within the first 24–72 hours of life) include the following (Kenner & Lott, 2014):

- No increased incidence of NEC
- Fewer days on total parenteral nutrition, thereby decreasing the incidence of cholestatic jaundice
- Increased weight gain
- Increased muscle maturation of the GI function, which can lead to improved feeding tolerance
- Lower risk of osteopenia
- Possible decrease in the total number of hospital days in the neonatal intensive care unit (NICU).

SAFETY ALERT Orogastric gavage catheter placement is preferable to nasogastric, because most neonates are obligatory nose breathers. If nasogastric is used, a #5 French catheter should be used to minimize airway obstruction.

Total Parenteral Nutrition

Total parenteral nutrition is used in situations that do not allow the neonate to be fed through the GI tract. This method provides complete nutrition to the neonate intravenously and uses hyperalimentation to provide calories, vitamins, minerals, protein, and glucose, and uses intra-lipids to provide essential fatty acids.

Fluid Requirements

The calculation of fluid requirements must take into account the neonate's weight and postnatal age. Recommendations for fluid therapy in the preterm neonate are approximately 80–100 mL/kg per day for the first day, 100–120 mL/kg per day for the second day, and 120–150 mL/kg per day by the third day of life. These amounts may be increased up to 200 mL/kg per day if the baby is very small, receiving phototherapy, or under a radiant warmer because of the increased insensible water losses. Fluid losses can be minimized through the use of heat shields and added humidification in the incubator. Daily weights (and, sometimes, twice-a-day weights) are the best indicator of fluid status in the preterm neonate. The expected weight loss during the first 3–5 days of life in a preterm neonate is 15–20% of birth weight. Premature newborns being treated for complications such as respiratory distress syndrome or patent ductus arteriosus may be on diuretics that can influence their fluid requirements.

Long-term Needs

The care of preterm neonates and their families does not stop on discharge from the nursery. Follow-up care is extremely important: Many developmental problems are not noted until an infant is older and begins to demonstrate motor delays or sensory disability.

Within the first year of life, low-birth-weight preterm babies face higher mortality rates than term babies. Causes of death include sudden infant death syndrome (SIDS)—which occurs about five times more frequently in the preterm baby than the term baby—respiratory infections, and neurologic defects. (See the exemplar on Sudden Infant Death Syndrome, in the module on Oxygenation.) Morbidity is also much higher among preterm babies, those weighing less than 1500 g being at the highest risk for long-term complications.

The most common long-term needs observed in preterm neonates include the following:

- **Retinopathy of prematurity (ROP).** Premature newborns are particularly susceptible to characteristic retinal changes, known as ROP, which can result in visual impairment. The premature newborn's retina does not have all of the blood vessels the term newborn's has. As the blood vessels fill in, they may grow abnormally with the development of fibrous tissue that can contract and scar, resulting in retinal detachment. The disease is now viewed as multifactorial in origin. Increased survival of very-low-birth-weight babies may be the most important factor in the increased incidence of ROP. The acute stages of ROP may be treated with laser photocoagulation and cryotherapy. Most acute changes with ROP regress spontaneously with no long-term visual impairment.

- **Bronchopulmonary dysplasia (BPD).** Long-term lung disease is a result of damage to the alveolar epithelium secondary to positive-pressure ventilator therapy and a high oxygen concentration. These babies have long-term dependence on oxygen therapy and an increased incidence of respiratory infection during their first few years of life.
- **Speech defects.** The most frequently observed speech defects involve delayed development of receptive and expressive ability that may persist into the school-age years.
- **Neurologic defects.** The most common neurologic defects include cerebral palsy (CP), hydrocephalus, seizure disorders, lower IQ, and learning disabilities. (See the exemplar on Cerebral Palsy in the module on Development.) In the absence of major neurologic defects, the socioeconomic climate and family support systems are extremely important influences on the child's eventual school performance. Families should be reminded that risk does not equal injury, injury does not equal damage, and description of damage does not allow a precise prediction about recovery or outcome.
- **Auditory defects.** Preterm babies have a 1–4% incidence of moderate to profound hearing loss and should have a formal audiologic exam before discharge and at 3–6 months (corrected age). Tests currently used to measure hearing functions of the newborn are the evoked otoacoustic emissions or the automated auditory brain response test. Any baby with repeated abnormal results should be referred to speech-and-language specialists.

When assessing the baby's abilities and disabilities, parents must understand that developmental progress must be evaluated on the basis of chronologic age from the expected date of birth, not from the actual date of birth (corrected age). In addition, the parents need the consistent support of healthcare professionals in the long-term management of their child. Many new and ongoing concerns arise as the former premature neonate grows and develops; the goal is to promote the highest quality of life possible.

Many hospitals and NICUs provide referrals for parents of premature babies to local child health service coordination and early intervention service programs. Early intervention services for newborns, infants, and toddlers are mandated under Part C of the Individuals with Disabilities in Education Act. Nurses working with these families, either in the NICU or hospital setting or in a pediatric setting, should be aware of their agency's referral process or know about services available in their area.

Alterations of Prematurity

The goals of medical and nursing care are to meet the preterm neonate's growth and development needs and to anticipate and manage the complications associated with prematurity. The most common alterations associated with prematurity are as follows:

1. **Apnea of prematurity.** Apnea of prematurity refers to cessation of breathing for 20 seconds or longer, or for less than 20 seconds when associated with cyanosis, pallor, and bradycardia. Apnea is a common problem

in the preterm neonate less than 36 weeks' gestation, presenting between day 2 and day 7 of life. The etiology of apnea is multifactorial, but it is thought to be primarily a result of neuronal immaturity. This factor contributes to the preterm neonate's irregular breathing patterns. Other causes of apnea are obstructive apnea and gastroesophageal reflux. Obstructive apnea can occur when cessation of airflow is associated with blockage of the upper airway (resulting from a small airway diameter, increased pharyngeal secretions, or altered body alignment and positioning). Gastroesophageal reflux is defined as a movement of gastric contents into the lower esophagus caused by poor esophageal sphincter tone, in turn causing laryngospasm, which leads to bradycardia and apnea. Apnea of prematurity is then a diagnosis of exclusion.

2. **Patent ductus arteriosus (PDA).** The ductus arteriosus fails to close because of decreased pulmonary arteriole musculature and hypoxemia. Symptomatic PDA is often seen around the time when premature neonates are recovering from respiratory distress syndrome. PDA often prolongs the course of illness in a preterm newborn and leads to chronic pulmonary dysfunction.

SAFETY ALERT A growing premature neonate who is showing clinical signs of worsening respiratory status (i.e., increased oxygen needs or increased ventilatory settings), acidosis, and hypotension may be exhibiting signs and symptoms of a PDA.

3. **Respiratory distress syndrome.** Respiratory distress results from inadequate surfactant production.
4. **Intraventricular hemorrhage.** Intraventricular hemorrhage is the most common type of intracranial hemorrhage in small preterm neonates, especially those weighing less than 1500 g or of those less than 34 weeks of gestation. Up to 34 weeks, the preterm neonate's brain ventricles are lined by the germinal matrix, which is highly susceptible to hypoxic events, such as respiratory distress, birth trauma, and birth asphyxia. The germinal matrix is highly vascular, and these blood vessels rupture in the presence of hypoxia.
5. **Anemia of prematurity.** The preterm neonate is at risk for anemia because of the rapid rate of growth required, shorter red blood cell life, excessive blood sampling, decreased iron stores, and deficiency of vitamin E. The hemoglobin usually reaches its lowest level by 3–12 weeks and remains low for 3–6 months.

SAFETY ALERT An extremely premature, low-birth-weight neonate who presents with a sudden drop in hemoglobin along with the onset of severe metabolic acidosis, a “waxy” color, and hypotension may have experienced an intracranial hemorrhage.

NURSING PROCESS

Subtle signs and symptoms can indicate a change in a newborn's condition that may require rapid interventions to prevent lifelong complications. Nurses who want to care for premature neonates must obtain postgraduation specialized education offered by the hospital.

Assessment

The nurse needs to assess the physical characteristics and gestational age of the preterm newborn accurately. This allows the healthcare team to anticipate the special needs and problems of the baby.

Determining gestational age in preterm newborns requires knowledge and experience in administering gestational assessment tools. The tool used should be specific, reliable, and valid.

Physical characteristics vary greatly depending on gestational age, but the following characteristics are frequently present:

- **Color** is usually pink or ruddy but may show acrocyanosis. (Cyanosis, jaundice, and pallor are abnormal and should be noted.)
- **Skin** is reddened and translucent, blood vessels are readily apparent, and there is little subcutaneous fat.
- **Lanugo** is plentiful and widely distributed.
- **Head size** appears large in relation to the body.
- **Skull bones** are pliable; fontanel is smooth and flat.
- **Ears** have minimal cartilage and are pliable, folded over.
- **Nails** are soft and short.
- **Testes** may not be descended and scrotum nonrugated.
- **Clitoris and labia minora** are prominent.
- **Resting position** is flaccid, frog-like.
- **Cry** is weak and feeble.
- **Reflexes** (sucking, swallowing, and gag) are poor.
- **Activity** consists of jerky, generalized movements. (Seizure activity is abnormal.)

Diagnosis

Nursing diagnoses that may apply to the preterm newborn include the following:

- *Impaired Gas Exchange* related to immature pulmonary vasculature and inadequate surfactant production
- *Ineffective Breathing Pattern* related to immature central nervous system
- *Risk for Decreased Cardiac Tissue Perfusion* related to hypotension related to decreased tissue perfusion secondary to PDA
- *Risk for Ineffective Peripheral Tissue Perfusion* related to anemia of prematurity
- *Imbalanced Nutrition Less than Body Requirements* related to weak suck-and-swallow reflexes and decreased ability to absorb nutrients
- *Ineffective Thermoregulation* related to hypothermia secondary to decreased glycogen and brown fat stores
- *Deficient Fluid Volume* related to high insensible water losses and inability of kidneys to concentrate urine
- *Compromised Family Coping* related to anger or guilt at having given birth to a premature baby.

(NANDA-I © 2014)

Planning

Important goals of nursing care for the premature neonate often include the following:

- The neonate's oxygenation and normal breathing patterns will be promoted.
- The neonate's weight gain and normal growth will be promoted.
- The neonate's developmental needs will be supported.
- The neonate's parents will be educated to provide care when discharged.
- The nurse will support the neonate's parents and suggest strategies to reduce parental anxiety.

Implementation

Priorities for care of the premature neonate are many. Maintenance of respiratory function, a neutral thermal environment, fluid and electrolyte status, and adequate nutrition are essential to giving the neonate the greatest chance for healthy growth and development. Prevention of infection and of fatigue during feeding is also important, as are promoting parent–newborn attachment and developmentally supportive care and preparing for home care (**Figure 33–96** »).

Maintain Respiratory Function

Premature newborns are at increased risk for respiratory obstruction because their bronchi and trachea are so narrow that mucus can obstruct the airway. The nurse must maintain patency through judicious suctioning, but only on an as-needed basis.

Positioning can also affect respiratory function. If the baby is in the supine position, the nurse should slightly elevate the head to maintain the airway, being careful to avoid hyperextension of the neck, which may cause the trachea to collapse. Also, because the newborn has weak neck muscles and cannot control head movement, place a small roll under the newborn's shoulders to maintain this head position. The

prone position splints the chest wall and decreases the amount of respiratory effort used to move the chest wall, facilitating chest expansion and improving air entry and oxygenation. Weak or absent cough or gag reflexes increase the chance of aspiration in the premature newborn. The nurse should ensure that the newborn's position facilitates drainage of mucus or regurgitated formula.

The nurse monitors heart and respiratory rates with cardiorespiratory monitors and observes the newborn to identify alterations in cardiopulmonary status. Signs of respiratory distress include the following:

- Cyanosis (serious sign when generalized)
- Tachypnea (sustained respiratory rate >60 breaths/min after first 4 hours of life)
- Retractions
- Expiratory grunting
- Nasal flaring
- Apneic episodes
- Presence of rales or rhonchi on auscultation
- Diminished air entry.

If respiratory distress occurs, the nurse administers oxygen per physician or nurse practitioner orders to relieve hypoxemia. If hypoxemia is not treated immediately, it may result in PDA or metabolic acidosis. If oxygen is administered to the newborn, the nurse monitors the oxygen concentration with a pulse oximeter and blood gas analysis. Periodic arterial blood gas sampling to monitor oxygen concentration in the baby's blood is essential because hyperoxemia may lead to ROP and other complications.

The nurse also needs to consider respiratory function before and during feedings. To prevent aspiration and increased energy expenditure and oxygen consumption, the nurse must ensure that the newborn's gag and suck reflexes are intact before starting oral feedings.

Maintain a Neutral Thermal Environment

A neutral thermal environment minimizes the oxygen consumption required to maintain a normal core temperature; it also prevents cold stress and facilitates growth by decreasing the calories needed to maintain body temperature. The preterm newborn's small brown fat stores and immature central nervous system provide poor temperature control. A small premature neonate (> 1200 g) can lose 80 kcal/kg per day through radiation of body heat. To minimize heat loss and temperature instability for preterm and low-birth-weight newborns, the nurse should do the following:

- Monitor ambient temperature of the room where the newborn is kept.
- Allow skin-to-skin contact (*kangaroo care*) between the parents and newborn to maintain warmth and foster security.
- Warm and humidify oxygen to minimize evaporative heat loss and decrease oxygen consumption.
- Place the baby in a double-walled incubator, or use a Plexiglas heat shield over small preterm neonates in single-walled incubators, to avoid radiative heat losses. Some institutions use radiant warmers and plastic wrap

Source: Carol Harrigan, RN, MSN, NNP-BC.

Figure 33–96 » Family bonding occurs when parents have opportunities to spend time with their premature newborn.

over the baby and pipe in humidity (swamping). Do not use Plexiglas shields on radiant warmer beds, however, because they block the infrared heat.

- Avoid placing the baby on cold surfaces, such as metal treatment tables and cold x-ray plates (conductive heat loss). Pad cold surfaces with diapers, and use radiant warmers during procedures. Place the preterm newborn on prewarmed mattresses, and warm hands before handling the baby to prevent heat transfer via conduction.
- Use warmed ambient humidity. Humidity can decrease insensible and transdermal water loss, especially in very-low-birth-weight newborns (Lund et al., 2013).
- Keep the newborn's skin dry (evaporative heat loss), and place a cap on the baby's head. The head makes up 25% of the total body size.
- Keep radiant warmers, incubators, and cribs away from windows or cold external walls (radiative heat loss) and out of drafts, which cause convection heat loss (conductive heat loss occurs when the newborn touches a cooler surface).
- Open incubator portholes and doors only when necessary, and use plastic sleeves on portholes to decrease convective heat loss.
- Use a skin probe to monitor the baby's skin temperature. Correlate ambient temperatures with the skin probe in the incubator using the servocontrol rather than the manual mode. The temperature should be 36°–37°C (96.8°–98.6°F). Temperature fluctuations indicate hypothermia or hyperthermia. Be careful not to place skin temperature probes over bony prominences; areas of brown fat; poorly vasoreactive areas, such as extremities; or excoriated areas.
- Warm formula or stored breast milk before feeding.
- Use a reflector patch over the skin temperature probe when using a radiant warmer bed so that the probe does not sense the higher infrared temperature as the baby's skin temperature and, therefore, decrease the heater output.

Once preterm newborns are medically stable, they can be clothed with a double-thickness cap, cotton shirt, and diaper and, if possible, swaddled in a blanket. The nurse begins the process of weaning to a crib when the premature newborn is medically stable, does not require assisted ventilation, weighs approximately 1500–2000 g (depending on facility policy), has had 5 days of consistent weight gain, and is taking oral feedings, and when apnea and bradycardia episodes have stabilized. The nurse should be familiar with the individual institution's protocol for weaning preterm babies to a crib.

Maintain Fluid and Electrolyte Status

The nurse maintains hydration by providing adequate fluid intake based on the newborn's weight, gestational age, chronological age, and volume of sensible and insensible water losses. Adequate fluid intake should compensate for increased insensible losses and the amount needed for renal excretion of metabolic products. Insensible water losses can be minimized by providing high ambient humidity, humidifying

oxygen, using heat shields, covering the skin with plastic wrap, and placing the newborn in a double-walled incubator.

The nurse evaluates the hydration status of the baby by assessing and recording signs of dehydration. Signs of dehydration include the following:

- Sunken fontanel
- Loss of weight
- Poor skin turgor (skin returns to position slowly when squeezed gently)
- Dry oral mucous membranes
- Decreased urine output
- Increased specific gravity (> 1.013).

The nurse must also identify signs of overhydration by observing the newborn for edema or excessive weight gain and by comparing urine output with fluid intake.

The nurse weighs the preterm newborn at least once daily at the same time each day. *Weight change is one of the most sensitive indicators of fluid balance.* Weighing diapers is also important for accurate input and output measurement (1 mL = 1 g). A comparison of intake and output measurements over an 8- or 24-hour period provides important information about renal function and fluid balance. Assessment of patterns, and whether they show a net gain or loss over several days, is also essential to fluid management. In addition, the nurse monitors blood serum levels and pH to evaluate for electrolyte imbalances.

Accurate hourly intake calculations are needed when administering intravenous (IV) fluids. Because the preterm newborn is unable to excrete excess fluid, it is essential for the nurse to maintain the correct amount of IV fluid to prevent overload. Accuracy can be ensured by using neonatal or pediatric infusion pumps. To prevent electrolyte imbalance and dehydration, the nurse takes care to give the correct IV solutions as well as the correct volumes and concentrations of formulas. Urine-specific gravity and pH are obtained periodically. Urine osmolality provides an indication of hydration, although this factor must be correlated with other assessments (e.g., serum sodium). Hydration is considered to be adequate when the urine output is 1–3 mL/kg per hour.

Provide Adequate Nutrition and Prevent Fatigue During Feeding

The preterm newborn's feeding abilities and health status determine the feeding method. Both nipple and gavage methods are initially supplemented with IV therapy until oral intake is sufficient to support growth (110–130 kcal/kg per day). Early, small-volume enteral feedings, called *minimal enteral nutrition via gavage*, have proven to be beneficial for the very-low-birth-weight newborn (see Gavage Feeding earlier in this exemplar). GI priming with these small-volume feedings is not intended to contribute to the total nutritional intake but, rather, to enhance gut metabolism. Trophic feedings may also help encourage earlier advancement to full feedings, thereby decreasing the development of necrotizing enterocolitis and the complications of parenteral nutrition. Formula or breast milk (with or without fortifiers to increase caloric content) is incorporated into the feedings

slowly. This is done to avoid overtaxing the digestive capacity of the preterm newborn. The nurse should carefully watch for any signs of feeding intolerance, including the following:

- Increasing gastric residuals
- Abdominal distention (measured routinely before feedings) with visible bowel loops
- Guaiac-positive stools (occult blood in stools)
- Lactose in stools (reducing substance in the stools)
- Vomiting
- Diarrhea
- Water-loss stools.

Before each feeding, the nurse measures abdominal girth and auscultates the abdomen to determine the presence and quality of bowel sounds. Such assessments permit early detection of abdominal distention, visible bowel loops, and decreased peristaltic activity, which may indicate necrotizing enterocolitis or paralytic ileus. The nurse also checks for residual formula in the stomach before feeding when the newborn is fed by gavage. This procedure also can be performed when the nipple-fed newborn presents with abdominal distention. The presence of increasing residual formula is an indication of intolerance to the type or amount of feeding or to the increase in amount of feeding.

SAFETY ALERT Residual feeding may indicate early necrotizing enterocolitis and should be called to the attention of the healthcare provider.

Preterm newborns who are ill or who fatigue easily with nipple feedings are usually fed by gavage. The neonate is essentially passive with these methods, thus conserving energy and calories. As the baby matures, gavage feedings are replaced with nipple (breast or formula) feedings to assist in strengthening the sucking reflex and in meeting the newborn's oral and emotional needs. While their nutrition may come from gavage feedings, nonnutritive sucking is important to the preterm newborn's development and should be encouraged. Signs that indicate readiness for oral feedings include a strong gag reflex, presence of nonnutritive sucking, and rooting behavior. Both low-birth-weight and preterm newborns nipple-feed more effectively in a quiet state. The nurse establishes a gradual nipple-feeding program, such as one nipple feeding per day, then one nipple feeding per shift, and then a nipple feeding every other feeding. The nurse should weigh the baby daily, because a small weight loss often occurs when nipple feedings are started. After feedings, the nurse places the baby on the right side (with support to maintain this position) or on the abdomen. These positions facilitate gastric emptying and decrease the chance of aspiration if regurgitation occurs. Gastroesophageal reflux is not uncommon in preterm newborns. Long-term gavage feeding may create nipple aversion that will require developmental occupational therapy interventions.

The nurse involves the parents in feeding their preterm baby. This is essential to the development of attachment between parents and baby. In addition, it increases parental knowledge about the care of their baby and helps them cope with the situation.

Prevent Infection

The nurse is responsible for minimizing the preterm newborn's exposure to pathogenic organisms. An immature immune system as well as thin and permeable skin make the preterm newborn susceptible to infection. Invasive procedures, techniques such as umbilical catheterization and mechanical ventilation, and prolonged hospitalization also place the neonate at greater risk for infection.

The practice of strict hand hygiene and use of separate equipment for each neonate help minimize the preterm newborn's exposure to infectious agents. Most nurseries have adopted the Centers for Disease Control and Prevention standard precautions of isolating every baby and the Joint Commission requirement that staff members have short-trimmed nails and no artificial nails. Staff members are required to complete a 2- to 3-minute scrub using an antibacterial solution, which inhibits growth of gram-positive cocci and gram-negative rod organisms. Other specific nursing interventions include limiting visitors, requiring visitors to wash their hands, maintaining strict aseptic practices when changing IV tubing and solutions (IV solutions and tubing should be changed every 24 hours or per agency protocols), administering parenteral fluids, and assisting with sterile procedures. Incubators and radiant warmers should be changed weekly. The nurse prevents pressure-area breakdown by changing the baby's position regularly, doing ROM exercises, and using water-bed pillows or an air mattress. To avoid skin tears, a protective, transparent covering can be applied over vulnerable joints; however, this method is used sparingly (Blackburn, 2013). Chemical skin preps and tape may cause skin trauma and should be avoided as much as possible.

If infection (sepsis) occurs in the preterm newborn, the nurse may be the first to identify its subtle clinical signs, such as lethargy and increased episodes of apnea and bradycardia. The nurse informs the healthcare provider of the findings immediately and implements the treatment plan per clinician orders in the presence of infection.

Promote Attachment

In some cases, preterm newborns are separated from their parents for prolonged periods after illness or complications that are detected in the first few hours or days following birth. This interrupts the bonding process, necessitating intervention to ensure successful attachment.

Nurses need to take measures to promote positive parental feelings toward the preterm newborn. They can give photographs of the baby to parents to take home. Photographs also may be given to the mother if she is in a different hospital or, if in the same hospital, is too ill to come to the nursery and visit. By placing the newborn's first name on the incubator as soon as it is known, nurses help the parents feel that their baby is a unique and special individual. A number of other interventions promote the bonding process, including the following:

- Give parents a weekly card with the baby's footprint, weight, and length.
- Give parents the telephone number of the nursery or intensive care unit and the names of staff members so that they have access to information about their baby at any time of the day or night.
- Encourage visits from siblings and grandparents.

Early involvement in the care of and decisions about their newborn provides the parents with realistic expectations for their baby. The individual personality characteristics of the newborn and the parents influence the bonding and contribute to the interactive process for the family. By observing each baby's patterns of behavior and responses, especially sleep-wake states, the nurse can teach parents the optimal times for interacting with their babies. The parents and nurse can plan nursing care around the times when the baby is alert and best able to attend.

Parents need education to develop caregiving skills and to understand the premature baby's behavioral characteristics. The more knowledge parents have about the meaning of their baby's responses, behaviors, and cues for interaction, the better they will be able to meet their newborn's needs and form a positive attachment with their child. For parents who cannot stay with their preterm baby, the nurse should encourage their daily participation (if possible) as well as early and frequent visits. The nurse should provide opportunities for parents to touch, hold, talk to, and care for the baby. Skin-to-skin holding (kangaroo care) helps parents feel close to their small newborn (**Figure 33-97** >>). Kangaroo care has been shown to improve sleep periods and parents' perception of their caregiving ability (Ludington-Hoe, 2013).

Some parents will progress easily to touching and cuddling their newborn; however, others will not. Parents need to know that their feelings are normal and that the progression of acquaintanceship can be slow. Rooming-in can provide another opportunity for the stable preterm newborn and family to get acquainted; it offers both privacy and readily available help.

Figure 33-97 >> Kangaroo (skin-to-skin) care facilitates closeness and attachment between mother and her premature newborn.

Promote Developmentally Supportive Care

Prolonged separation and the NICU environment necessitate individualized baby sensory stimulation programs. Developmentally supportive care (DSC) interventions include music therapy, light touch, massage, and vestibular stimulation (Westrup, 2014). The nurse plays a key role in determining the appropriate type and amount of visual, tactile, and auditory stimulation.

Some preterm newborns are not developmentally able to deal with more than one sensory input at a time. To ensure that the DSC interventions help the promotion of developmental support while simultaneously not inducing stress to the preterm newborn, a tool for assessing the behavior of preterm babies following provision of a DSC intervention in the NICU was developed (D'Souza, Kumar, & Lewis, 2014). This tool is used to assess the preterm newborn's behavior using two scales: autonomic/visceral system (color, respiration, visceral, and neurophysiologic responses) and the state and attention-interaction system (state regulation, auditory stimulus, and alertness). The preterm baby's behavioral reactions to stimulation are observed, and developmental interventions are then based on reducing detrimental environmental stimuli to the lowest possible level and providing appropriate opportunities for development (Blackburn, 2013).

Providing developmentally supportive, family-centered care improves the outcomes of the critically ill newborn. With this in mind, specially designed NICUs with the single-room care concept are being developed to minimize lighting and noise as well as to provide privacy for the parents of the convalescing newborn (White, Smith, & Shepley, 2013).

The NICU environment contains many detrimental stimuli that the nurse can help reduce. Simple actions that nurses can take include the following:

- If possible, replace alarms with lights to lower noise levels.
- Silence alarms quickly.
- Keep conversations away from newborns' bedsides.
- Use dimmer switches to shield newborns' eyes from bright lights.
- Place blankets over the top portion of each incubator.

Nursing care should also be planned to decrease the number of times the baby is disturbed. Signs (e.g., "Quiet Please") can be placed near the bedside to allow the baby some periods of uninterrupted sleep (Blackburn, 2013).

Some other suggested developmentally supportive interventions include the following:

- Facilitate handling by using containment measures when turning or moving the neonate or doing procedures such as suctioning. Use the hands to hold the neonate's arms and legs flexed close to the midline of the body. This helps stabilize the newborn's motor and physiologic subsystems during stressful activities.
- Touch the preemie gently, and avoid sudden postural changes.
- Promote self-consoling and soothing activities, such as placing blanket rolls or approved manufactured devices next to the neonate's sides and against the feet to provide

Source: Carol Harrigan, RN, MSN, NNP-BC.

Figure 33-98 » A 3-week-old, 31 weeks' gestational age baby is nestled and developmentally positioned. Hand-to-mouth behavior facilitates self-consoling and soothing activities.

"nesting." Swaddle the preemie to maintain extremities in a flexed position while ensuring that the hands can reach the face. This permits the newborn to do hand-to-mouth activities, which can be consoling (**Figure 33-98** »).

- Simulate the kinesthetic advantages of the intrauterine environment by using sheepskin and approved water beds. Water bed and pillow use has been reported to improve sleep and decrease motor activity as well as lead to more mature motor behavior, fewer state changes, and a decreased heart rate.
- Provide opportunities for nonnutritive sucking with a pacifier (**Figure 33-99** »). This improves transcutaneous oxygen saturation; decreases body movements; improves sleep, especially after feedings; and increases weight gain.
- Provide objects for the preemie to grasp (e.g., a piece of blanket, oxygen tubing, or a finger) during caregiving. Grasping may comfort the baby.

The nurse teaches the parents how to read behavioral cues to help them move at their baby's own pace when providing stimulation. Parents are ideally equipped to meet the baby's need for stimulation. Stroking, rocking, cuddling, quiet singing, and talking to the baby can all be integral parts of the baby's care. Visual stimulation in the form of *en face* interaction with caregivers and mobiles is also important (see Figure 33-58).

Kangaroo (skin-to-skin) care is becoming more prevalent in NICUs across the United States (see Figure 33-97). It was first practiced in Bogota, Colombia, in the early 1980s because of fear about the spread of infection by sharing incubators. Skin-to-skin care is defined as the practice of holding newborns skin-to-skin against their parents. The newborn is

Source: Carol Harrigan, RN, MSN, NNP-BC.

Figure 33-99 » Nonnutritive sucking on a pacifier has a calming effect on the preterm newborn and also facilitates readiness to bottle-feed.

usually naked, except for a diaper, and is placed on his or her parent's bare chest. They are then both covered with a blanket. Benefits of skin-to-skin care as a developmental intervention include the following (Ludington-Hoe, 2013):

- Improved oxygenation, as evidenced by an increase in oxygen saturation levels
- Enhanced temperature regulation
- Decline in the episodes of apnea and bradycardia
- Increased periods of quiet sleep
- Stabilization of vital signs
- Positive interaction between parent and baby, which enhances attachment and bonding
- Increased growth parameters
- Early discharge.

Skin-to-skin care may be limited because of staff uneasiness when moving the neonate while attached to multiple IV lines, monitor leads, and a ventilator. The confines of the nursery may be another limiting factor.

Music therapy as a noninvasive auditory stimulus has been shown to be advantageous in full-term newborns but has not been well studied in the premature neonate (Loewy et al., 2012). The music used in NICUs primarily includes lullabies and soft acoustical pieces that are pleasant, soothing, and calming. Such music has been shown to affect newborn physiologic responses, such as improving oxygenation and increasing weight gain. It also has behavioral effects, leading to enhanced parental bonding and increased intervals of nonnutritive sucking periods. Language development is also enhanced if the music is live and sung by the mother or another woman, which is preferential to the newborn. However, the overall noise level in the NICU needs to be considered before including any extra auditory stimulation, including music therapy (Kassity-Krich & Jones, 2014).

Massage and *gentle touch* have been practiced for many centuries. The types of stimulation include massage with

stroking, gentle touch without stroking, and therapeutic touch or “hands-on” containment. Practitioners report such physiologic benefits as stimulating blood and lymphatic flow, promoting weight gain in premature newborns, and regulating sleep patterns (Smith, 2012). Many emotional and behavioral benefits are also cited by practitioners. Classes are available to teach parents how to perform massage on their babies. Massage demonstrates compassion while increasing the parent’s empathy and understanding of the baby. It helps parents learn to interpret their baby’s behavioral cues, such as facial expression, various crying patterns, and other body language. At the same time, it helps newborns learn about their various body parts and boundaries and feel how those integrate into the whole. Therapeutic touch reduces motor activity and energy expenditure by the newborn and also promotes comfort.

For ways to help new parents with a compromised newborn, see Patient Teaching: Parent Support.

Prepare for Home Care

Parents are often anxious when their premature newborn is transferred out of the NICU or is discharged home. Parents of preterm babies should receive the same postpartum teaching as any parent taking a new baby home. In preparing for discharge, the nurse encourages the parents to spend time caring directly for their baby. This familiarizes them with their baby’s behavior patterns and helps them establish realistic expectations about the baby. Some hospitals have a special room near the nursery where parents can spend the night with their baby before discharge.

Discharge instruction includes breastfeeding and formula-feeding techniques, formula preparation, and vitamin administration. If the mother wishes to breastfeed, the nurse teaches her to pump her breasts to keep the milk flowing and provide milk even before discharge. The nurse gives information on bathing, diapering, hygiene, and normal elimination patterns and prepares the parents to expect changes in the color of the baby’s stool, number of bowel

movements, and timing of elimination when the baby is switched from formula-feeding to breastfeeding. This information can prevent unnecessary concern by the parents. The nurse also discusses normal growth and development patterns, reflexes, and activity for preterm newborns. In these discussions, the nurse should emphasize ways to promote bonding behaviors and deal with newborn crying. Caring for the preemie with complications, preventing infections, recognizing signs of a sick baby, and the need for continued medical follow-up are other key issues.

Families with preterm newborns usually do not need to be referred to community agencies, such as visiting nurse assistance. However, referral may be necessary if the preemie has severe congenital abnormalities, feeding problems, or complications with infections or respiratory problems, or if the parents seem unable to cope with an at-risk baby. Parents of preterm babies can benefit from meeting with others in a similar situation to share common experiences and concerns. Nurses should refer parents to support groups sponsored by the hospital or by others in the community and make connections for parents with early education intervention centers.

Preterm and low-birth-weight babies are at greater risk of increased morbidity from vaccine-preventable diseases (AAP & ACOG, 2012). The optimal timing to initiate hepatitis B therapy in preterm newborns weighing less than 2000 g whose mothers are hepatitis B surface antigen negative has not been determined. Preterm newborns who weigh less than 2000 g and are medically stable and thriving do show consistently high rates of seroconversion following the first dose of hepatitis B vaccine, even when the first dose is given as early as 1 month after birth (AAP & ACOG, 2012). The medically stable preterm baby and low-birth-weight baby should receive full doses of diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b, poliovirus, and pneumococcal conjugate vaccines at a chronologic age consistent with the schedule recommended for full-term babies (AAP & ACOG, 2012). The influenza vaccine should be administered at 6 months of age before the beginning of and during the influenza season. Palivizumab for respiratory syncytial virus (RSV) should be administered during the local RSV season and before hospital discharge to preterm newborns born at less than 35 weeks of gestation as well as to those with bronchopulmonary dysplasia or congenital heart disease (AAP & ACOG, 2012). Immunoprophylaxis should be continued on a monthly basis until the local RSV season ends.

Evaluation

Expected outcomes of nursing care include the following:

- The preterm newborn is free of respiratory distress and establishes effective respiratory function.
- The preterm newborn gains weight and shows no signs of fatigue or aspiration during feedings.
- The preterm newborn demonstrates a serial head circumference growth rate of 1 cm (0.4 in.) per week.
- The parents are able to verbalize their feelings of anger and guilt about the birth of a preterm baby and show attachment behavior, such as frequent visits and growing confidence in their participatory care activities.

Patient Teaching

Parent Support

Although birth is often a highly anticipated and exciting experience, this event does not always result in the delivery of the healthy baby parents anticipate. When parents realize their newborn is not the “perfect” child they hoped for, both mothers and fathers experience an acute grief reaction (Valizadeh, Zamanzadeh, & Rahiminia, 2013). Whether related to prematurity or congenital anomaly, the birth of a seriously compromised baby may cause parents to experience anticipatory grief before an actual loss occurs. It is important to note that mothers and fathers may express grief in different ways. Women are more likely to openly express emotions and reactions associated with grief, while men may suppress their feelings because of their supportive and protective role (Valizadeh et al., 2013). Because nurses often participate in end-of-life care for critically ill babies and their families, they must be acutely aware of these differences and equipped to offer appropriate support measures. For more information, see the module on Grief and Loss.

Conducting additional care evaluation determines if further care is needed based on newborn outcomes. If the outcomes are not being met, the nurse may choose to continue or revise the plan of care for optimal outcome attainment.

Continuation, revision, or discontinuation of a plan of care is decided through collaboration of all members of the health-care team.

Nursing Care Plan

A Premature Newborn

Baby Boy Johnson was born 12 weeks early at 28 weeks of gestation to Dennis and Alaina Johnson. He is their first child. The NICU nurse received the baby from the obstetrician after he was delivered vaginally. Apgar scoring was 5 at 1 minute, 5 at 5 minutes, and 4 at 10 minutes. He had a weak cry and was dusky and floppy, with an initial heart rate of greater than 100 beats/min. During resuscitation, the nurse provided blow-by oxygen. When his oxygenation status not only failed to improve but dropped, indicating that resuscitation was not effective, the nurse practitioner inserted

an oral endotracheal tube, and oxygen was administered by bagging. He was transported to the NICU in a warm isolette where he was admitted, placed on a ventilator, and had an umbilical artery catheter placed.

His parents come to see him when his mother is moved from the labor area to her room on the postpartum unit. Their first question to the nurse is "Is he okay?" Their next question is "When will he be able to come home?" The nurse encourages his parents to touch him and talk to him before they leave the nursery.

ASSESSMENT	DIAGNOSES	PLANNING
<ul style="list-style-type: none"> Vital signs 36°C (96.7°F) axillary; pulse 172 beats/min; respiration 68/min; BP 42/24 mmHg Endotracheal tube taped in place to ventilator set to deliver 30 breaths/minute, with 4 mmHg of positive end-expiratory pressure Color pink with acrocyanosis Soft murmur audible in left midaxillary area Hypoactive bowel sounds in all quadrants Has not voided or stoolled yet 	<ul style="list-style-type: none"> <i>Ineffective Airway Clearance</i> secondary to prematurity <i>Attachment, Risk for Impaired</i> <i>Body Temperature: Imbalanced, Risk for</i> <i>Gas Exchange, Impaired</i> <p>(NANDA-I © 2014)</p>	<ul style="list-style-type: none"> The newborn will maintain adequate gas exchange to meet tissue requirements. The newborn will maintain a clear airway to promote oxygenation. The parents will bond with the newborn and recognize the characteristics of their baby. The newborn will receive adequate nutrition and fluid to promote growth.

IMPLEMENTATION

<ul style="list-style-type: none"> Suction endotracheal tube as needed when secretions are heard in endotracheal tube. Monitor arterial blood gas studies to determine adequate gas exchange. Assist with surfactant administration as ordered to reduce alveolar collapse on expiration. Monitor daily weights. Monitor urine output and kidney function by testing urine for pH and specific gravity. Encourage parents to visit as often as possible, and point out the newborn's characteristics to help parents focus on the baby instead of the medical equipment. Assist parents to hold their baby, and offer the option of skin-to-skin (kangaroo) care to promote attachment. 	<ul style="list-style-type: none"> Monitor cardiorespiratory and oxygen saturation on a continuous basis. Change pulse oximeter location frequently (at least every 2 hours) to reduce the risk of altered skin integrity. Avoid use of tape to reduce altered skin integrity. Promote development by offering a pacifier for the newborn to suck on. Provide periods of reduced stimulation to promote rest and comfort. Maintain neonate in a neutral thermal environment, either on a radiant warmer or a heated isolette, until he is able to maintain a normal temperature independently. Monitor vital signs at a minimum of every 4 hours.
--	---

EVALUATION

After administration of surfactant, Baby Boy Johnson is extubated, placed on CPAP for 2 days, and then weaned to nasal cannula. Feedings are initiated via continuous gavage feedings. Once feedings are tolerated, he is changed to every-3-hour feedings. His murmur is diagnosed as a patent ductus arteriosus (PDA), and indomethacin is administered, which successfully closes the PDA.

He begins to have occasional apneic episodes and is placed on caffeine every 12 hours.

Within 4 weeks, he is showing steady weight gain and is moved to the low-risk NICU. His parents begin participating more in providing care, such as bathing and feeding him, and he is discharged at 12 weeks of age.

CRITICAL THINKING

- How would you respond to the parents when they ask when the baby is likely to come home?
- How can you maintain the neonate's temperature while he is being held by his parents?
- If the neonate weighs 900 g, what are his fluid and caloric needs per day?

REVIEW Prematurity

RELATE Link the Concepts and Exemplars

Linking the exemplar of prematurity to the concept of grief and loss:

1. What factors might induce feelings of loss for the parents of a premature newborn, even if the newborn is doing well?
2. What nursing interventions would you implement to help the parents who are feeling grief and loss over the birth of their premature newborn?

Linking the exemplar of prematurity with the concept of development:

3. What developmental needs does a premature newborn have?
4. What nursing care would you provide the premature newborn in order to promote development?

REFLECT Apply Your Knowledge

Jessica Marshall, 15 years old, delivers a baby girl at 32 weeks of gestation. Jessica sees her baby briefly in the delivery room before the newborn is transported to the NICU. Jessica names the baby Shamika, after her best friend. On the way from the labor and delivery recovery room, the nurse brings Jessica to the nursery to see the baby, who is under an oxygen hood with an IV through her umbilicus and cardiac monitor leads on her chest. When Jessica sees her baby, she begins to cry and says, "She's so small and looks so sick. It's all my fault!" The nurse caring for Shamika points out the baby's beautiful curly hair, long fingers, and aquiline nose. Jessica stops crying and says, "Oh, you're right. Look how beautiful she is—and so perfect." Shamika's nurse takes Jessica to her new room, gives her some information about premature babies to read, and encourages her to come back to visit Shamika as soon as she feels up to it.

1. When assigned to care for Shamika, what nursing diagnoses would you consider to be the greatest priority regarding this family?
2. How would you help Jessica bond with her premature newborn?
3. What risks does this premature newborn face as the result of being born to an adolescent mother?

Part IV

Nursing Domain

Part IV consists of modules that define and outline principles of nursing care, including assessment, clinical decision making, and communication. Each module presents a concept that directly relates to professional nursing and its impact on patient health and well-being and selected principles or topics of that concept presented as exemplars. In

the concept of clinical decision making, for example, the exemplars include the nursing process, the nursing plan of care, and prioritizing care. Each module addresses the impact of that concept and selected exemplars on the care of individuals across the lifespan, inclusive of cultural, gender, and developmental considerations.

Module 34 Assessment 2429

Module 35 Caring Interventions 2461

Module 36 Clinical Decision Making 2479

Module 37 Collaboration 2543

Module 38 Communication 2557

Module 39 Managing Care 2615

Module 40 Professionalism 2645

Module 41 Teaching and Learning 2661

Module 34

Assessment

Module Outline and Learning Outcomes

The Concept of Assessment

Types and Sources of Data

34.1 Analyze the types and sources of data collected during a nursing assessment.

Collecting Data

34.2 Analyze the principal methods used to collect data during a nursing assessment.

Organizing Data

34.3 Analyze various methods of organizing assessment data.

Validating Data

34.4 Analyze the need for validating data collected during the nursing assessment.

Interpreting Data

34.5 Analyze the factors used when interpreting data from a nursing assessment.

Concepts Related to Assessment

34.6 Outline the relationship between assessment and other concepts.

Holistic Health Assessment Across the Lifespan

34.7 Differentiate considerations related to the assessment of patients throughout the lifespan.

>> The Concept of Assessment

Concept Key Terms

Assessment, 2429	Flatness, 2442	Neutral question, 2434	Palpation, 2439	Signs, 2430

Health **assessment** is a systematic method of collecting data about a patient for the purpose of determining the patient's current and ongoing health status, predicting risks to health, and identifying health-promoting activities (D'Amico & Barbarito, 2015). The focus of an assessment includes the problems presented by the patient and relevant physical, social, cultural, environmental, and emotional factors that affect the overall well-being of the patient. Data gathered about the patient's health status include wellness behaviors, illness and injury signs and symptoms, patient strengths and weaknesses, health history, and risk factors.

Use of effective communication techniques and critical thinking skills help the nurse gather the detailed, complete, relevant data needed to formulate a patient's plan of care. Health assessment includes the interview and physical

assessment, which must be documented and interpreted. All future patient care is directed by the interpretation of findings from data collected throughout the assessment process.

Four different types of assessments are used: initial (or baseline) assessment, problem-focused (or system-specific) assessment, emergency assessment, and ongoing reassessment (see **Table 34-1** >>>).

Types and Sources of Data

Data collection is the process of gathering information about a patient's health status. It must be both systematic and continuous to prevent the omission of significant data and to reflect a patient's changing health status. Data can be constant or variable. Constant data is information that does not

TABLE 34–1 Types of Assessment

Type	Time Performed	Purpose	Example
Initial (or baseline) assessment	Performed within a specified time frame after admission to a healthcare agency (Refer to agency policy and procedure)	<ul style="list-style-type: none"> To establish a baseline for problem identification, reference, and future comparison 	<ul style="list-style-type: none"> Nursing admission assessment
Problem-focused (or system-specific) assessment	Ongoing process integrated with nursing care	<ul style="list-style-type: none"> To determine the status of a specific problem identified in an earlier assessment 	<ul style="list-style-type: none"> Hourly assessment of patient's fluid intake and urinary output in an intensive care unit (ICU) Assessment of patient's ability to perform self-care while assisting a patient to bathe
Emergency assessment	During any physiologic or psychologic crisis	<ul style="list-style-type: none"> To identify life-threatening problems To identify new or overlooked critical problems 	<ul style="list-style-type: none"> Rapid assessment of open airway, breathing status, and circulation during a cardiac arrest Assessment of suicidal tendencies or potential for violence
Ongoing reassessment	Minutes to months after initial assessment	<ul style="list-style-type: none"> To compare the patient's current status to baseline data previously obtained 	<ul style="list-style-type: none"> Reassessment of a patient's functional health patterns in a home care or out-patient setting, or change-of-shift assessments in an acute or long-term care facility

change over time, such as race or blood type. Variable data can change quickly, frequently, or rarely, and include data such as blood pressure, age, and level of pain.

A **clinical database** includes the nursing health history, physical assessment, primary care provider's history and physical examination, results of laboratory and diagnostic tests, and material contributed by other health personnel.

Patient data should include past history as well as current problems. For example, a previous allergic reaction to penicillin is a vital piece of historical data. Past surgical procedures, complementary or integrative health approaches that the patient has used, and chronic diseases are also examples of historical data. Current data relate to present circumstances, such as pain, nausea, sleep patterns, and religious practices. To ensure accuracy, both the patient and the nurse must participate actively in the data collection process.

Types of Data

Subjective data, also referred to as **symptoms**, are feelings or perceptions that can be described or verified only by the patient. Itching, pain, and feelings of anxiety are examples of subjective data. Subjective data include the patient's sensations (e.g., numbness, cold, tingling), feelings, values, beliefs, attitudes, and perception of personal health status and life situation.

Objective data, also referred to as **signs**, are detectable by an observer or can be measured or tested against an accepted standard. They can be seen, heard, felt, or smelled, and they are obtained by observation or physical examination. Examples of objective data include a discoloration of the skin and a blood pressure reading. During the physical examination, the nurse obtains objective data to validate subjective data and to complete the assessment phase of the nursing process.

Sources of Data

Sources of data are primary or secondary. The patient is the primary source of data. Family members or other support

people, other healthcare professionals, records and reports, laboratory and diagnostic analyses, and relevant literature are secondary or indirect sources. In fact, all sources other than the patient are considered secondary sources. (Blood pressure measurements obtained by using an external cuff and manometer may be considered secondary or indirect data because they do not directly measure the pressure within the arteries.) All data from secondary sources should be validated if possible.

Patient

The best source of data is usually the patient, unless the patient is too ill, young, or confused to communicate clearly. The patient can provide subjective data that no one else can offer. Most often, primary data refer to statements made by the patient but also include the objective data that the nurse can obtain directly from the patient, such as gender. Some patients cannot or do not wish to provide accurate data. These include young children and patients who are confused, afraid, embarrassed, or distrustful or who do not speak the nurse's language (D'Amico & Barbarito, 2015).

Support People

Family members, friends, and caregivers who know the patient well often can supplement or verify information provided by the patient. They may convey information about the patient's response to illness, the stresses the patient was experiencing before the illness, family attitudes on illness and health, and the patient's home environment.

Support people are an especially important source of data for a patient who is very young, unconscious, or confused. In some cases—a patient who is physically or emotionally abused, for example—the individual giving information may wish to remain anonymous. Before eliciting data from support people, the nurse should ensure that the patient, if mentally able, approves the gathering of such input. The nurse should also indicate on the nursing history that the data were obtained from a support person.

Information supplied by family members, significant others, or other healthcare professionals is considered subjective if it is not based on fact. If a patient's daughter says, "Dad is very confused today," that is secondary subjective data because it is an interpretation of the patient's behavior by the daughter. The nurse should attempt to verify the reported confusion by interviewing the patient directly. However, if the daughter says, "Dad said he thought it was the year 1941 today," that may be considered secondary objective data because the daughter heard her father state this directly.

The presence or absence of support people in a patient's life can itself be a significant assessment finding. A young child who is brought in for a clinic visit by foster parents will require a different combination of assessment tools than a child who is brought in by his or her own parent. Similarly, an older patient who lives alone and is suspected of having dementia will require an assessment that differs from that of a healthy older patient who lives an active life with his or her spouse.

Patient Records

Patient records include information documented by various healthcare professionals. Patient records also contain data regarding the patient's occupation, religion, and marital status. By reviewing such records before interviewing the patient, the nurse can avoid asking questions for which answers have already been supplied. Repeated questioning can be stressful and annoying to patients and may cause concern about the lack of communication among health professionals. Types of patient records include medical records, records of therapies, and laboratory records.

Medical records (e.g., medical history, physical examinations, operative reports, progress notes, discharge summaries, consultations with specialists) provide information about a patient's present and past health, illness, and injury patterns. These records also can provide the nurse with information about the patient's coping behaviors, health practices, and allergies.

Records of therapies provided by other health professionals, such as social workers, nutritionists, dietitians, or physical therapists, help the nurse obtain relevant data not expressed by the patient. For example, a social service agency's report on a patient's living conditions or a home healthcare agency's report on a patient's self-care abilities can inform the nurse's assessment of the patient.

Laboratory records are another source of pertinent health information. For example, the determination of blood glucose level allows healthcare professionals to monitor the administration of oral hypoglycemic medications. Any laboratory data about a patient must be compared to the agency or performing laboratory's norms for that particular test, taking into account the patient's age, gender, and other significant patient data.

» Go to **Pearson MyLab Nursing and eText** to access Appendix B for descriptions of diagnostic studies and their normal values.

The nurse must always consider the information in patient records in light of the present situation. For example, if the most recent medical record is 10 years old, the patient's health practices and coping behaviors are likely to have changed. Older patients may have numerous previous

records. These can be useful to understanding the patient's health history, especially if the patient's memory is impaired.

Healthcare Professionals

Because assessment is an ongoing process, verbal reports from other healthcare professionals serve as potential sources of information about a patient's health. Nurses, social workers, primary care providers, and physiotherapists, for example, may have information from either previous or current contact with the patient. Sharing of information among professionals is especially important to ensure continuity of care when patients are transferred to and from home and healthcare agencies.

Literature

Nursing and related literature, such as professional journals and reference texts, can provide additional information to assist the nurse in developing or interpreting an assessment. The nurse may review literature to gather additional information on one or more of the following:

- Standards or norms against which to compare findings (e.g., height and weight tables, normal developmental tasks for an age group)
- Cultural and social health practices
- Spiritual beliefs
- Assessment data needed for specific patient conditions
- Nursing interventions and evaluation criteria relevant to a patient's health problems
- Medical diagnoses, treatments, and prognoses
- Current methodologies and research findings.

Collecting Data

The principal methods used to collect data are observing, interviewing, and examining. Observation occurs whenever the nurse is in contact with the patient or support people. Interviewing is used mainly when the nurse is taking the nursing health history. Examining is the major method used in the physical health assessment.

In reality, the nurse uses all three methods simultaneously. For example, during the patient interview the nurse observes, listens, asks questions, and mentally retains information to explore in the physical examination. These topics are covered further in the module on Communication.

Observing

Observation has two aspects: (a) noticing the data and (b) selecting, organizing, and interpreting the data (**Table 34-2** »). A nurse who observes that a patient's face is flushed must relate that observation to findings such as body temperature, activity, environmental temperature, and blood pressure. The nurse often needs to focus on specific data to avoid being overwhelmed by a multitude of data. Observing, therefore, involves distinguishing data in a meaningful manner. For example, nurses caring for newborns learn to ignore the usual sounds of machines in the nursery but respond quickly to an infant's cry or movement. Errors can occur in selecting, organizing, and interpreting data. For example, a nurse might not notice certain signs, either

TABLE 34-2 Using the Senses to Observe Patient Data

Sense	Example of Patient Data
Vision	Overall appearance (e.g., body size, general weight, posture, grooming); signs of distress or discomfort; facial and body gestures; skin color and lesions; abnormalities of movement; nonverbal demeanor (e.g., signs of anger or anxiety); religious or cultural artifacts (e.g., books, icons, candles, beads)
Smell	Body or breath odors
Hearing	Lung and heart sounds; bowel sounds; ability to communicate; language spoken; ability to initiate conversation; ability to respond when spoken to; orientation to time, person, and place; thoughts and feelings about self, others, and health status
Touch	Skin temperature and moisture; muscle strength (e.g., hand grip); pulse rate, rhythm, and volume; palpatory lesions (e.g., lumps, masses, nodules)

because they are unexpected or because they do not conform to preconceptions about a patient’s health.

The experienced nurse is often able to attend to an intervention (e.g., give a bed bath or monitor an intravenous infusion) and at the same time make important observations (e.g., note a change in respiratory status or skin color). The beginning student must learn to make observations and complete tasks simultaneously.

Interviewing

An **interview** is a planned communication or a conversation with a purpose. Interviews may be used to get or give information, identify problems of mutual concern, evaluate change, teach, and provide support, counseling, or therapy.

One example of the interview is the nursing health history, which is a part of the nursing admission assessment. See **Box 34-1** » for the components of a nursing health history.

Nurses use two approaches to interviewing: directive and nondirective. The **directive interview** is highly structured and elicits specific information. The nurse establishes the purpose of the interview and controls the interview—at least at the outset. The patient responds to questions but may have limited opportunity to ask questions or discuss concerns. Nurses frequently use directive interviews to gather and to give information when time is limited (e.g., in an emergency situation).

During a **nondirective interview**, or rapport-building interview, the nurse allows the patient to control the purpose, subject matter, and pacing. **Rapport** is an understanding between two or more people.

A combination of directive and nondirective approaches is usually appropriate during the information-gathering interview. The nurse begins by determining areas of concern for the patient. If, for example, a patient expresses worry about surgery, the nurse pauses to explore the patient’s worry and to provide support. Simply noting the worry, without dealing with it, can leave the impression that the nurse does not care about the patient’s concerns or dismisses them as unimportant.

Planning the Interview

Before beginning an interview, the nurse reviews available information (for example, the operative report), information about the current illness, or literature about the patient’s health problem. The nurse also reviews the agency’s data collection

form to identify which data must be collected and which data are within the nurse’s discretion to collect based on the specific patient. If a form is not available, most nurses prepare an interview guide to help them remember areas of information and determine what questions to ask. The guide includes a list of topics and subtopics rather than a series of questions.

Both nurses and patients should be comfortable in order to encourage an effective interview by balancing several factors. Each interview is influenced by time, place, seating arrangement or distance, and language.

Time

If possible, the nurse plans interviews with patients when the patient is physically comfortable and free of pain, and when interruptions by friends, family, and other health professionals are minimal. The nurse should schedule interviews with patients in their homes at a time selected by the patient.

Place

A well-lighted, well-ventilated room that is relatively free of noise, movements, and distractions encourages communication. A place where others cannot overhear or see the patient is essential.

Seating Arrangement

The nurse who stands and looks down at a patient who is in bed or in a chair risks intimidating the patient. When a patient is in bed, the nurse can sit at a 45-degree angle to the bed. This position is less formal than sitting behind a table or standing at the foot of the bed. During an initial admission interview, a patient who is in bed may feel less confronted if an overbed table is placed between the patient and the nurse. A seating arrangement with the nurse behind a desk and the patient seated across creates a formal setting that suggests a business meeting between a superior and a subordinate. In contrast, a seating arrangement in which the parties sit on two chairs placed at right angles to a desk or table or a few feet apart, with no table between, creates a less formal atmosphere, and the nurse and patient tend to feel on equal terms (**Figure 34-1** »). In groups, a horseshoe or circular chair arrangement can avoid a superior or head-of-the-table position.

Source: Sturti/E+/Getty Images.

Figure 34-1 » A seating arrangement in which the nurse and patient sit on two chairs placed at right angles to a desk puts them on equal terms.

Box 34–1

Components of a Nursing Health History

Biographical Data

The patient's name, address, age, sex, marital status, occupation, religious preference, healthcare financing, and usual source of medical care.

Chief Complaint or Reason for Visit

The chief complaint is the answer given to the question "What is troubling you?" or "Can you tell me the reason you came to the hospital or clinic today?" It should be recorded in the patient's own words.

History of Present Illness

- When the symptoms started
- Whether the onset of symptoms was sudden or gradual
- How often the problem occurs
- Exact location of the distress
- Character of the complaint (e.g., intensity of pain or quality of sputum, emesis, or discharge)
- Activity in which the patient was involved when the problem occurred
- Phenomena or symptoms associated with the chief complaint
- Factors that aggravate or alleviate the problem

Past History

- **Childhood illnesses**, such as chickenpox, mumps, measles, rubella (German measles), rubeola (red measles), streptococcal infections, scarlet fever, rheumatic fever, and other significant illnesses
- **Childhood immunizations** and the date of the last tetanus shot
- **Allergies** to drugs, animals, insects, or other environmental agents; the type of reaction that occurs; and how the reaction is treated
- **Accidents and injuries**: how, when, and where the incident occurred, type of injury, treatment received, and any complications
- **Hospitalization for serious illnesses**: reasons for the hospitalization, dates, surgery performed, course of recovery, and any complications
- **Medications and supplements**: all currently used prescription and over-the-counter medications, such as aspirin, nasal spray, vitamins, or laxatives
- **Complementary and integrative health approaches**: use of Chinese herbs, chiropractic medicine, acupuncture, or any traditional forms of treatment associated with cultural heritage or spiritual beliefs

Family History of Illness

To ascertain risk factors for certain diseases, the ages of siblings, parents, and grandparents and their current state of health or, if they are deceased, the cause of death are obtained. Particular attention should be given to disorders such as heart disease, cancer, diabetes, hypertension, obesity, allergies, arthritis, tuberculosis, bleeding, alcoholism, and any mental health disorders.

Lifestyle

- **Personal habits**: the amount, frequency, and duration of use of tobacco, alcohol, coffee, cola, tea, and illicit or recreational drugs
- **Diet**: description of a typical diet on a normal day or any special diet, number of meals and snacks per day, who cooks

and shops for food, ethnically distinct food patterns, and food allergies

- **Sleep/rest patterns**: usual daily sleep–wake times, difficulties sleeping, and remedies used for difficulties
- **Activities of daily living (ADLs)**: any difficulties experienced in the basic activities of eating, grooming, dressing, elimination, and locomotion
- **Instrumental ADLs (iADLs)**: any difficulties experienced in food preparation, shopping, transportation, housekeeping, laundry, and ability to use the telephone, handle finances, and manage medications
- **Recreation/hobbies**: exercise activity and tolerance, hobbies and other interests, and vacations

Social Data

- **Family relationships/friendships**: the patient's support system in times of stress or need, what effect the patient's illness has on the family, and whether any family problems are affecting the patient
- **Ethnic affiliation**: health customs and beliefs; cultural practices that may affect healthcare and recovery
- **Educational history**: data about the patient's highest level of education attained and any past difficulties with learning
- **Occupational history**: current employment status, the number of days missed from work because of illness, any history of accidents on the job, any occupational hazards with a potential for future disease or accident, the patient's need to change jobs because of past illness, the employment status of spouses or partners and the way child care is handled, and the patient's overall satisfaction with the work
- **Economic status**: information about how the patient is paying for medical care (including what kind of medical and hospitalization coverage the patient has) and whether the patient's illness presents financial concerns
- **Home and neighborhood conditions**: home safety measures and adjustments in physical facilities that may be required to help the patient manage a physical disability, activity intolerance, and ADLs; the availability of neighborhood and community services to meet the patient's needs

Psychologic Data

- **Major stressors** experienced and the patient's perception of them
- **Usual coping pattern** with a serious problem or a high level of stress
- **Communication style**, or the ability to verbalize appropriate emotion; nonverbal communication—such as eye movements, gestures, use of touch, and posture; interactions with support people; and the congruence of nonverbal behavior and verbal expression

Patterns of Healthcare

Patterns of healthcare are all healthcare resources the patient is currently using and has used in the past. These include the primary care provider, specialists (e.g., ophthalmologist or gynecologist), dentist, traditional healers or folk practitioners (e.g., herbalist or *curandero*), health clinic, or health center; whether the patient considers the care being provided adequate; and whether access to healthcare is a problem.

Distance

The distance between the nurse and patient should be neither too small nor too great, because people feel uncomfortable when talking to someone who is too close or too far away. Most people in Western cultures feel comfortable maintaining a distance of 2–3 feet during an interview. Some patients require more or less personal space, depending on their cultural and personal needs.

Language

Failure to communicate in a language the patient can understand is a form of discrimination. The nurse must convert complicated medical terminology into common English usage. Interpreters or translators are needed if the patient and the nurse do not speak the same language or dialect (a variation in a language spoken in a particular geographic region). Translating medical terminology is a specialized skill because not all individuals who are fluent in the conversational form of a language are familiar with anatomic or other health terms. Interpreters, however, may make judgments about precise wording but also about subtle meanings that require additional explanation or clarification according to the specific language and ethnicity. Interpreters may also edit the original source to make the meaning clearer or more culturally appropriate.

If giving written documents to a patient, the nurse must determine whether the patient can read them, or if a translator is required. Live translation is preferred, because the patient can then ask questions for clarification. Services such as the commercial LanguageLine Solutions are available 24 hours a day in over 200 languages for a fee. Many large agencies have their own on-call translator services for the languages or dialects commonly spoken in their area.

SAFETY ALERT Check your healthcare institution's policies about offering language translation services. Nurses might be required to offer professional translators, rather than asking family members to translate for the patient. The concern is that family members may insert their own advice or alter information to reduce anxiety in the patient. Using patient visitors and agency nonprofessional staff should be avoided for reasons of confidentiality. It is important to remember that some patients may be more comfortable with an interviewer or translator who is of the same gender as the patient.

Even among patients who speak English, there may be differences in understanding terminology. Patients from different parts of the country may have strong accents, and teen patients and patients who are less well educated may ascribe different meanings to words. For example, “cool” may imply something good to one patient and something not warm to another. For some teens and young adults, the term “sick” means something very good. The nurse must always confirm accurate understandings.

Types of Interview Questions

Questions are often classified as closed or open ended, and neutral or leading. **Closed questions**, used in the directive interview, are restrictive and generally require only “yes” or “no” or short factual answers giving specific information. Closed questions often begin with “when,” “where,” “who,” “what,” “do (did, does),” or “is (are, was).” Examples of

closed questions are “What medication did you take?” “Are you having pain now? Show me where it is.” “How old are you?” “When did you fall?” The highly stressed individual and the individual who has difficulty communicating will find closed questions easier to answer than open-ended questions.

Open-ended questions, associated with the nondirective interview, invite patients to discover and explore, elaborate, clarify, or illustrate their thoughts or feelings. An open-ended question specifies only the broad topic to be discussed and invites answers longer than one or two words. Such questions give patients the freedom to divulge only the information that they are ready to disclose. The open-ended question is useful at the beginning of an interview or to change topics and to elicit attitudes.

Open-ended questions may begin with “what” or “how.” Examples of open-ended questions are “How have you been feeling lately?” “What brought you to the hospital?” “How did you feel in that situation?” “Would you describe more about how you relate to your child?” “What would you like to talk about today?”

Nurses often find it necessary to use a combination of closed and open-ended questions throughout an interview to accomplish the goals of the interview and obtain needed information. See **Box 34-2** for advantages and disadvantages of open-ended and closed questions.

A **neutral question** is a question that the patient can answer without direction or pressure from the nurse, is open ended, and is used in nondirective interviews. Examples are “How do you feel about that?” and “Why do you think you had the operation?” A **leading question**, by contrast, is usually closed, used in a directive interview, and thus directs the patient’s answer. Examples are “You’re stressed about surgery tomorrow, aren’t you?” “You will take your medicine, won’t you?” The leading question gives the patient less opportunity to decide whether the answer is true or not. Leading questions create problems if the patient, in an effort to please the nurse, gives inaccurate responses. This can result in inaccurate data, which can negatively affect nursing care.

Stages of an Interview

An interview has three major stages: the opening or introduction, the body or development, and the closing (Stewart & Cash, 2014).

The Opening

The opening can be the most important part of an interview because it sets the tone for the remainder of the interview. What the nurse says, how the nurse says it, and the attitude the nurse projects to the patient can make a huge difference in the patient’s attitude. The purposes of the opening are to establish rapport and orient the interviewee.

Establishing rapport is a process of creating goodwill and trust. It can begin with a greeting (“Good morning, Mr. Johnson”) or a self-introduction (“Good morning. I’m Taylor James, a nursing student”) accompanied by non-verbal gestures such as a smile, a handshake, and a friendly manner. The nurse must be careful not to overdo this stage; too much superficial talk can arouse anxiety and may appear insincere.

Box 34–2

Selected Advantages and Disadvantages of Open-Ended and Closed Questions

OPEN-ENDED QUESTIONS

Advantages	Disadvantages
<ul style="list-style-type: none"> They develop trust. They let the patient do the talking. The nurse is able to listen and observe. They are easy for the patient to answer. They reveal what the patient thinks is important. They may reveal the patient's lack of knowledge. They can provide information the nurse may not ask for. 	<ul style="list-style-type: none"> They take more time. Patients may give only brief answers. Valuable information may be withheld. They can result in more information than necessary. Responses may be difficult to document. The nurse requires skill in controlling an open-ended interview. There may be language barriers if the nurse and patient don't have the same first language.

CLOSED QUESTIONS

Advantages	Disadvantages
<ul style="list-style-type: none"> Questions and answers can be controlled more effectively. They require less effort from the patient. They may be less threatening because they do not require explanations or justifications. They take less time. Information can be asked for sooner than it would be volunteered. Responses are easily documented. 	<ul style="list-style-type: none"> They may provide too little information and require follow-up questions. They may not reveal how the patient feels. They do not allow the patient to volunteer possibly valuable information. They may inhibit communication and convey lack of interest by the nurse. The nurse may dominate the interview with questions.

In orientation, the nurse explains the purpose and nature of the interview, for example, what information is needed, how long it will take, and what is expected of the patient. The nurse tells the patient how the information will be used and usually states that the patient has the right not to provide information.

The following is an example of an interview introduction:

Step 1—Establish rapport:

Nurse: Hello, Ms. Goodwin, I'm Letisha Fellows. I'm a nursing student, and I'll be assisting with your care here today.

Patient: Hi. Are you a student from the college?

Nurse: Yes, I'm in my final year. Are you familiar with the campus?

Patient: Oh, yes! I'm an avid basketball fan. My nephew graduated from there, and I often attend basketball games with him.

Nurse: That's great! Sounds like fun.

Patient: Yes, I enjoy it very much.

Step 2—Orientation

Nurse: May I sit down with you for about 10 minutes to talk about how I can help you while you're here?

Patient: All right. What do you want to know?

Nurse: To help plan your care after your operation, I'd like to get some information about your usual daily activities and what you expect here in the hospital. I'll take notes while we talk to get the important points

and have them available to the other staff who will also look after you.

Patient: OK. That's all right with me.

Nurse: If there is anything you don't want to talk about, please feel free to say so. Everything you tell me will be confidential and will be shared only with others who have the legal right to know it.

Patient: Sure, that will be fine.

The Body

In the body of the interview, the patient communicates what he or she thinks, feels, knows, and perceives in response to questions from the nurse. Effective development of the interview demands that the nurse use communication techniques that make both parties feel comfortable and serve the purpose of the interview. For communicating during an interview, follow these guidelines:

- Listen attentively, using all your senses, and speak slowly and clearly.
- Use language the patient understands, and clarify points that are not understood.
- Plan questions to follow a logical sequence.
- Ask only one question at a time. Multiple questions limit the patient to one choice and may confuse the patient.
- Acknowledge the patient's right to look at things the way they appear to him or her and not the way they appear to the nurse or someone else.

- Do not impose your own values on the patient.
- Avoid giving personal viewpoints or advice, such as saying, “If I were you. . . .”
- Nonverbally convey respect, concern, interest, and acceptance.
- Be aware of the patient’s and your own body language.
- Be conscious of the patient’s and your own voice inflection, tone, and affect.
- Sit down to talk with the patient (be at an even level).
- Use and accept silence to help the patient search for more thoughts or to organize them.
- Use eye contact and be calm, unhurried, and sympathetic.

The Closing

The nurse terminates the interview when the necessary information has been obtained. In some cases, however, a patient terminates the interview. For example, the patient may decide not to give any more information or may be unable to offer more information for some other reason—fatigue, for example. The closing is important for maintaining the rapport and trust and for facilitating future interactions. The following techniques are commonly used to close an interview:

1. **Offer to answer questions.** “Do you have any questions?” or “I would be glad to answer any questions you have.” Be sure to allow time for the individual to answer, or the offer will be regarded as insincere.
2. **Conclude by saying.** “Well, that’s all I need to know for now” or “Well, those are all the questions I have for now.” Preceding a remark with the word “well” generally signals that the end of the interaction is near.
3. **Thank the patient.** “Thank you for your time and help. The questions you have answered will be helpful in planning your nursing care.” You may also shake the patient’s hand.
4. **Express concern for the patient’s welfare and future.** “Take care of yourself. I hope all goes well for you.”
5. **Plan for the next meeting,** if there is to be one, or state what will happen next. Include the day, time, place, topic, and purpose: “Let’s get together again here on the fifteenth at 9:00 a.m. to see how you are managing then.” Or “Ms. Cho, I will be responsible for giving you care three mornings per week while you are here. I will be in to see you each Monday, Tuesday, and Wednesday between eight o’clock and noon. At those times, we can adjust your care as needed.”
6. **Provide a summary to verify accuracy and agreement.** Summarizing serves several purposes, such as helping to terminate the interview, reassuring the patient that the nurse has listened, checking the accuracy of the nurse’s perceptions, clearing the way for new ideas, and helping the patient to note progress and a forward direction: “Let’s review what we have just covered in this interview.” Summaries are particularly helpful for patients who are anxious or who have difficulty staying with the topic: “Well, it seems to me that you are especially worried about your hospitalization and chest pain because your father died of a

heart attack 5 years ago. Is that correct? . . . I’ll discuss this with you again tomorrow, and we’ll decide what plans need to be made to help you.”

Clinical Example A

Martha Whitman is a 59-year-old recently retired elementary school teacher who complains of continued acute back pain. The findings from the physical assessment are all within normal limits. Ms. Whitman states that the pain started 2 weeks ago and has been getting worse, with only temporary relief with the use of aspirin. Before referring this patient for diagnostic studies, the nurse asks about any activities or events associated with the onset of the pain. Ms. Whitman reveals that she had enthusiastically taken up a new hobby of quilting about 3 weeks ago. She has been sitting and working with an embroidery hoop almost every day for an hour or two. In addition, she proudly adds that her garden “has never looked better—not a weed in sight!”

Critical Thinking Questions

1. How does the additional interview information assist the nurse in interpretation of Ms. Whitman’s back pain?
2. What recommendations could the nurse make to prevent further straining the muscles of Ms. Whitman’s back?
3. What timetable should the nurse give Ms. Whitman to expect decreased symptoms? What is the plan if this target date is not met?

Examining

The physical examination or physical assessment is a systematic data collection method that uses observation (i.e., the senses of sight, hearing, smell, and touch) to detect health problems. To conduct the examination, the nurse uses techniques of inspection, auscultation, palpation, and percussion.

The purposes of a physical examination include the following:

- To obtain baseline data about the patient’s functional abilities
- To supplement, confirm, or refute data obtained in the nursing history
- To obtain data that will help establish nursing diagnoses and plans of care
- To evaluate the physiologic outcomes of healthcare and thus the progress of a patient in relation to health problems
- To make clinical judgments about a patient’s health status
- To identify areas for health promotion and disease prevention.

A physical examination can be any of three types: (1) an initial assessment (e.g., when a patient is admitted to a healthcare agency), (2) a system-specific examination (e.g., the cardiovascular system), or (3) an examination of a body area (e.g., the lungs, when difficulty with breathing is observed). Most physical examinations begin by taking the patient’s vital signs. **Table 34-3** » lists normal vital signs across the lifespan.

Physical examinations typically reveal normal and abnormal findings. The nurse must analyze both types of findings and make critical decisions about their meaning and importance. For example, when the patient is being admitted with

TABLE 34-3 Normal Vital Sign Ranges Across the Lifespan^a

	Pulse (per minute) ^b	Respirations (per minute) ^b	Temperature (°C) ^c	Blood Pressure (mmHg) ^d	
				Systolic	Diastolic
Newborn	100–205 (awake) 90–160 (asleep)	30–80	Normal range: 36.5–37.5	At birth: 50–70 ^e At day 10: 90	At birth: 30–45 ^e At day 10: 50
Infant	100–180 (awake) 80–160 (asleep)	30–60	Normal range (axillary): 36.5–37.5	Age 1 Boys: 80–89 Girls: 83–90	Age 1 Boys: 34–39 Girls: 38–42
Toddler	98–140 (awake) 80–120 (asleep)	20–40	Normal range: 36–38.5 Extreme range: 35–40	Age 2 Boys: 84–92 Girls: 85–91	Age 2 Boys: 39–44 Girls: 43–47
Preschooler	98–140 (awake) 80–120 (asleep)	22–34	Normal range: 36–38.5 Extreme range: 35–40	Age 4 Boys: 88–97 Girls: 88–94	Age 4 Boys: 47–52 Girls: 50–54
School age	70–120 (awake) 50–90 (asleep)	15–25	Normal range: 36–38.5 Extreme range: 35–40	Age 9 Boys: 95–104 Girls: 96–103	Age 9 Boys: 57–62 Girls: 58–61
Adolescent	50–90	12–20	Normal range: 36–38.5 Extreme range: 35–40	Age 15 Boys: 109–117 Girls: 107–113	Age 15 Boys: 61–66 Girls: 64–67
Adult	60–100	12–20	Normal range: 36–38.5 Extreme range: 35–40	Less than 120	Less than 80
Older adult	60–100	15–20	Normal range: 36–38.5 Extreme range: 35–40	Less than 120	Less than 80

Notes:

- a. There is a wide variety of “normal” at each stage of the lifespan, and vital signs are dynamic. While these ranges provide a general sense of the norm, it is important for the nurse to determine what “normal” is for each patient and to base further considerations on those parameters and the context of the patient presentation.
- b. The ranges for pulse and respiration change dramatically from birth through adolescence, and then remain fairly stable throughout the rest of life.
- c. The first set of numbers in each cell is the usual range of temperature; the second set shows extremes of normal temperature for when the weather is very cold, when it is early in the morning, or during exercise.
- d. Data from American Heart Association (AHA). (2015). *Understanding blood pressure readings*. Retrieved from http://www.heart.org/HEARTORG/Conditions/HighBloodPressure/AboutHighBloodPressure/Understanding-Blood-Pressure-Readings_UCM_301764_Article.jsp
Note that blood pressure readings for children are determined using the child's height percentile. The blood pressure values presented here are the 50th percentile for the child's age, sex, and height, which are considered the midpoint of the normal range. A reading above the 95th percentile indicates hypertension. To see the pediatric blood pressure tables, visit <http://www.nhlbi.nih.gov/health-pro/guidelines/current/hypertension-pediatric-jnc-4/blood-pressure-tables.htm>
- e. Blood pressure is usually monitored before age 3 only if the patient has cardiac issues.

a diagnosis of appendicitis, the presence of pain in the right lower quadrant would be an expected initial finding, while a later absence of pain in that same location might indicate that the appendix has ruptured.

When findings are different than anticipated, the nurse must make decisions about their importance and what to do with the information. If unsure about the significance of a finding or to whom it should be reported, the nurse should consult with a more experienced nurse regarding the best course of action to follow.

A complete physical examination starts at the head and proceeds in a systematic manner downward (head-to-toe assessment), by body systems (neurologic system, respiratory system, and so forth), or by a combination of the two organizing principles. As shown in **Box 34-3** », Assessment of an Adolescent Woman, the physical examination starts with the upper part of the body before proceeding to a review of body systems.

Whichever approach is used, the nurse must adapt the examination according to the age of the individual, the severity of the illness, the preferences of the nurse and patient, the environment for the examination, and the agency's policies and procedures. Regardless of the procedure used, the patient's energy level and time constraints need to be considered. The physical assessment is conducted in a systematic and efficient manner with the fewest position changes for the patient.

Frequently, nurses assess a specific body area, instead of the entire body. These specific assessments are made in relation to patient complaints, the nurse's observations, the patient's presenting problem, available nursing interventions, and medical therapies. Examples of these situations and assessments are provided in **Table 34-4** ».

Nurses use national guidelines and evidence-based practice while performing health assessments. For example, when screening for cancer, the nurse should keep in mind

Box 34–3

Assessment of an Adolescent Woman

General Health State (*present weight—gain or loss, reason for gain or loss, amount of time for gain or loss; fatigue, malaise, weakness, sweats, night sweats, chills*):

Skin (*history of skin disease, pigment or color change, change in mole, excessive dryness or moisture, pruritus, excessive bruising, rash or lesion*):

Hair (*recent loss or change in texture*):

Nails (*change in color, shape, brittleness*):

Head (*unusual headaches, frequency of headaches, head injury, dizziness, syncope or vertigo*):

Eyes (*difficulty or change in vision, decreased acuity, blurring, blind spots, eye pain, diplopia, redness or swelling, watering or discharge, glaucoma or cataracts*):

Ears (*earaches, infections, discharge and its characteristics, tinnitus or vertigo*):

Nose and Sinuses (*discharge and its characteristics, frequent or severe colds, sinus pain, nasal obstruction, nosebleeds, seasonal allergies, change in sense of smell*):

Mouth and Throat (*mouth pain, sore throat, bleeding gums, toothache, lesions in mouth, tongue, or throat, dysphagia, hoarseness, tonsillectomy, alteration in taste*):

Neck (*pain, limitation of motion, lumps or swelling, enlarged or tender lymph nodes, goiter*):

Neurologic System (*history of seizure disorder, syncopal episodes, CVA, motor function or coordination disorders/abnormalities, paresthesia, mood change, depression, memory disorder, history of mental health disorders*):

Endocrine System (*history of diabetes or insulin resistance, history of thyroid disease, intolerance to heat or cold*):

Breast and Axilla (*pain, lump, tenderness, swelling, rash, nipple discharge, any breast surgery*):

Respiratory System (*History of lung disease, smoking, chest pain with breathing, wheezing, shortness of breath, cough—productive or nonproductive. Sputum—color and amount. Hemoptysis, toxin or pollution exposure*):

Cardiac System (*history of cardiac disease, MI, atherosclerosis, arteriosclerosis, chest pain, angina*):

Peripheral Vascular System (*coldness, numbness, tingling, swelling of legs/ankles, discoloration of hands/feet, varicose veins, intermittent claudication, thrombophlebitis or ulcers*):

Hematologic System (*bleeding tendency of skin or mucous membranes, excessive bruising, swelling of lymph nodes, blood transfusion and any reactions, exposure to toxic agents or radiation*):

Gastrointestinal System (*appetite, food intolerance, dysphagia, heartburn, indigestion, pain [with eating or other], pyrosis, nausea, vomiting, history of abdominal disease, gastric ulcers, flatulence, bowel movement frequency, change in stool [color, consistency], diarrhea, constipation, hemorrhoids, rectal bleeding*):

Musculoskeletal System (*history of arthritis, joint pain, stiffness, swelling, deformity, limitation of motion, pain, cramps, or weakness*):

Urinary System (*recent change, frequency, urgency, nocturia, dysuria, polyuria, oliguria, hesitancy or straining, urine color, narrowed stream, incontinence; history of urinary disease; pain in flank, groin, suprapubic region or low back*):

Female Genital System (*menstrual history, age of first menses, last menstrual cycle, frequency of cycles, premenstrual pain, vaginal itching, discharge, premenopausal symptoms, age at menopause, postmenopausal bleeding*):

Sexual Health (*presently involved in relationship involving intercourse or other sexual activity, aspects of sex satisfactory, use of contraceptive, is relationship monogamous, history of STD*):

TABLE 34–4 Nursing Assessments Addressing Selected Patient Situations

Situation	Physical Assessment
Patient complains of abdominal pain.	Inspect, auscultate, and palpate the abdomen; assess vital signs.
Patient is admitted with a head injury.	Assess level of consciousness using the Glasgow Coma Scale (discussed in the module on Intracranial Regulation); assess pupils for reaction to light and accommodation; assess vital signs.
Nurse prepares to administer a cardiotonic drug to a patient.	Assess apical pulse, compare with baseline data and clinical standards for continued administration.
Patient has just had a cast applied to the lower leg.	Assess peripheral perfusion of toes, capillary refill, pedal pulse if accessible, and vital signs.
Patient's fluid intake is minimal.	Assess skin turgor, fluid intake and output, and vital signs.
Patient's spouse reports that the patient with limited mobility is "not making sense."	Assess vital signs. Check patient's body for signs that indicate fall or injury. Assess pupils for reactions to light and accommodation.
Patient is curled up in a fetal position, holding his head between his hands.	Assess the vital signs, including the possibility of pain or withdrawal. Palpate the forehead to check for elevated temperature.
Patient is throwing items around his hospital room.	Make contact with patient to calm him down before taking vital signs.
Patient receiving a blood transfusion reports "itchy skin."	Stop transfusion. Take vital signs and inspect the chest skin for signs of rash.
Parents report their child is unresponsive.	Assess the child's A, B, Cs (airway, breathing, circulation). Intervene as needed.

the American Cancer Society's guidelines (2017) for early detection. These guidelines include methods for early identification of breast, colorectal, cervical, endometrial, lung, and prostate cancers.

» **Stay Current:** Visit the American Cancer Society website at www.cancer.org/healthy/findcancerearly/cancerscreeningguidelines/american-cancer-society-guidelines-for-the-early-detection-of-cancer to see their guidelines for early detection of cancer.

Preparing the Patient

Most patients need an explanation of the physical examination process. Often patients are anxious about what the nurse will find. The nurse provides reassurance by explaining each step of the examination. The nurse should explain when and where the examination will take place, why it is important, and what will happen, while ensuring the patient assents to each stage of the examination, an important component of informed consent. The nurse should inform the patient that all information gathered and documented during the assessment is kept confidential in accordance with the Health Insurance Portability and Accountability Act (HIPAA). Only healthcare providers who have a legitimate need to know the patient's information will have access to it. That may include health insurance companies in addition to clinicians.

Health examinations are usually painless; however, it is important to determine in advance any positions contraindicated for a particular patient. For example, patients having difficulty breathing may experience increased difficulty when lying in a supine position. The nurse assists the patient as needed to undress and put on a gown. Patients should empty their bladders before the examination. Doing so helps them feel more relaxed and facilitates palpation of the abdomen and pubic area. If a urinalysis is required, the urine should be collected in a container for that purpose.

Preparing the Environment

It is important to prepare the environment before starting the assessment. The time for the physical assessment should be convenient to both the patient and the nurse. The environment should be well lighted and the equipment organized for efficient use. A patient who is physically relaxed will usually experience little discomfort. The room should be warm enough to be comfortable for the patient.

Providing privacy is important. Most people are embarrassed if their bodies are exposed or if others can overhear or view them during the assessment. Culture, age, and gender of both the patient and the nurse influence how comfortable the patient will be and what special arrangements may be needed. For example, if the patient and nurse are of different genders, the nurse should ask if it is acceptable to perform the physical examination or if a nurse of the same gender is preferred. Family and friends should not be present unless the patient asks for someone.

Positioning

During the physical examination, the patient may need to maintain several positions. The nurse must consider the patient's ability to assume each position before asking him or her to do so. The patient's physical condition, energy level, and age should also be taken into consideration. Some

positions are embarrassing or uncomfortable and therefore should not be maintained for extended periods. By organizing the assessment so that several body areas can be assessed in one position, the nurse can minimize the number of position changes needed and maximize the patient's comfort during the assessment (see **Table 34-5** »).

Methods of Examining

Four primary techniques are used in the physical examination: inspection, palpation, percussion, and auscultation. Each requires practice to develop expertise.

Inspection

Inspection is visual examination, or assessment using the sense of sight. The process should be deliberate, purposeful, and systematic. The nurse inspects with the naked eye and with a lighted instrument such as an otoscope (used to view the ear). In addition to visual observations, olfactory (smell) and auditory (hearing) cues are noted. Nurses frequently use visual inspection to assess moisture, color, and texture of body surfaces, as well as shape, position, size, color, and symmetry of the body. Lighting must be sufficient for the nurse to see clearly; either natural or artificial light can be used. When using the auditory senses it is important to have a quiet environment. Observation can be combined with the other assessment techniques.

Palpation

Palpation is the examination of the body using the sense of touch. The pads of the fingers are used because their concentration of nerve endings makes them highly sensitive to tactile discrimination. Palpation is used to determine the following characteristics:

- Texture (e.g., of the hair)
- Temperature (e.g., of a skin area)
- Moisture
- Vibration (e.g., of a joint)
- Swelling
- Rigidity or spasticity
- Crepitation
- Location, position, size, consistency, and mobility of organs, lumps, or masses
- Distention (e.g., of the urinary bladder)
- Amplitude of pulses
- The presence of tenderness or pain.

There are two types of palpation: light and deep. Light (superficial) palpation should always precede deep palpation because heavy pressure on the fingertips can dull the sense of touch. For light palpation, the nurse extends the dominant hand's fingers parallel to the skin surface and presses gently while moving the hand in a circle (see **Figure 34-2** »). With light palpation, the skin is slightly depressed. If it is necessary to determine the details of a mass, the nurse presses lightly several times rather than holding the pressure. See **Table 34-6** » for the characteristics of masses.

Deep palpation is done with one hand or with two hands (bimanually). In deep bimanual palpation, the nurse extends

TABLE 34-5 Patient Positions and Body Areas Assessed

Position	Description	Areas Assessed	Cautions
Dorsal recumbent 	Back-lying position with knees flexed and hips externally rotated; small pillow under the head; soles of feet on the surface	Female genitals, rectum, and female reproductive tract	May be contraindicated for patients who have cardiopulmonary problems.
Supine (horizontal recumbent) 	Back-lying position with legs extended; with or without pillow under the head	Head, neck, axillae, anterior thorax, lungs, breasts, heart, vital signs, abdomen, extremities, peripheral pulses	Tolerated poorly by patients with cardiovascular and respiratory problems.
Sitting 	A seated position, back unsupported and legs hanging freely	Head, neck, posterior and anterior thorax, lungs, breasts, axillae, heart, vital signs, upper and lower extremities, reflexes	Older adults and weak patients may require support.
Lithotomy 	Back-lying position with feet supported in stirrups; the hips should be in line with the edge of the table	Female genitals, rectum, and female reproductive tract	May be uncomfortable and tiring for older adults and embarrassing for most patients.
Sims 	Side-lying position with lowermost arm behind the body, uppermost leg flexed at hip and knee, upper arm flexed at shoulder and elbow	Rectum, vagina	Difficult for older adults and people with limited joint movement.
Prone 	Lies on abdomen with head turned to the side, with or without a small pillow	Posterior thorax, hip joint movement	Often not tolerated by older adults and people with cardiovascular, neuromuscular, and respiratory problems.

the dominant hand as for light palpation, then places the finger pads of the nondominant hand on the dorsal surface of the distal interphalangeal joints of the middle three fingers of the dominant hand (**Figure 34-3** »). The top hand applies pressure while the lower hand remains relaxed to perceive the tactile sensations. For deep palpation using one hand, the finger pads of the dominant hand press over the area to

be palpated. Often the other hand is used to support a mass or organ from below (**Figure 34-4** »). Deep palpation is usually not done during a routine examination and requires significant practitioner skill. It is performed with extreme caution because pressure can damage internal organs. Deep palpation is usually not indicated in patients who have acute abdominal pain or pain that is not yet diagnosed.

Figure 34-2 » The position of the hand for light palpation.

Figure 34-3 » The position of the hands for deep bimanual palpation.

Figure 34-4 » Deep palpation using the lower hand to support the body while the upper hand palpates the organ.

TABLE 34-6 Characteristics of Masses

Characteristic	Descriptors
Location	Site on the body, dorsal/ventral surface
Size	Length and width in centimeters
Shape	Oval, round, elongated, irregular
Consistency	Soft, firm, hard
Surface	Smooth, nodular
Mobility	Fixed, mobile
Pulsatility	Present or absent
Tenderness	Degree of tenderness to palpation

To test skin temperature, the nurse should use the dorsal aspect (back) of the hand and fingers where the skin is thinnest. To test for vibration, the nurse should use the base of the fingers (metacarpophalangeal joints) or ulnar surface of the hand. General guidelines for palpation include the following:

- The nurse's hands should be clean and warm, and the fingernails should be short.
- Palpation technique should be slow and systematic.
- Areas of tenderness should be palpated last.

The effectiveness of palpation depends largely on the patient's level of relaxation. The nurse can assist a patient to relax by (a) gowning and/or draping the patient appropriately, (b) positioning the patient comfortably, and (c) ensuring that the nurse's own hands are warm before beginning. During palpation, the nurse should be sensitive to the patient's verbal and nonverbal communications indicating discomfort.

Percussion

Percussion is the act of striking the body surface to elicit sounds that can be heard or vibrations that can be felt. There are two types of percussion: direct and indirect. In *direct percussion*, the nurse strikes the area to be percussed directly with the pads of two, three, or four fingers or with the pad of the middle finger. The strikes are rapid, and the movement is from the wrist (see **Figure 34-5** »).

Figure 34-5 » Direct percussion, in which one hand is used to strike the surface of the body.

Figure 34-6 » Indirect percussion, in which the finger of one hand taps the finger of the other hand.

Indirect percussion refers to the striking of an object (e.g., a finger) held against the body area to be examined. In this technique, the middle finger of the nondominant hand, referred to as the **pleximeter**, is placed firmly on the patient’s skin. Only the distal phalanx and joint of this finger should be in contact with the skin. Using the tip of the flexed middle finger of the other hand, called the **plexor**, the nurse strikes the pleximeter, usually at the distal interphalangeal joint (see **Figure 34-6 »**). Some nurses may find a point between the distal and proximal joints to be a more comfortable pleximeter point. The motion comes from the wrist; the forearm remains stationary. The angle between the plexor and the pleximeter should be 90 degrees, and the blows must be firm, rapid, and short to obtain a clear sound.

Percussion is used to determine the size and shape of internal organs by establishing their borders. It indicates whether tissue is fluid filled, air filled, or solid. Percussion elicits five types of sound: flatness, dullness, resonance, hyperresonance, and tympany. **Flatness** is an extremely dull sound produced by very dense tissue, such as muscle or bone. **Dullness** is a thudlike sound produced by dense tissue such as the liver, spleen, or heart. **Resonance** is a hollow sound, such as that produced by lungs filled with air. **Hyperresonance** is not produced in the healthy body. It is described as booming that can be heard over an emphysematous lung. **Tympany** is a musical or drumlike sound produced from an air-filled stomach. On a continuum, flatness reflects the most

dense tissue (the least amount of air) and tympany the least dense tissue (the greatest amount of air). A percussion sound is described according to its intensity, pitch, duration, and quality (see **Table 34-7 »**).

Auscultation

Auscultation is the process of listening to sounds produced within the body. Auscultation may be direct or indirect. An example of *direct auscultation* is the use of the unaided ear to listen to a respiratory wheeze or the grating of a moving joint. *Indirect auscultation* refers to the use of a stethoscope, which transmits the sounds to the nurse’s ears. A stethoscope is used primarily to listen to sounds from within the body, such as bowel sounds or valve sounds of the heart and blood pressure.

The stethoscope tubing should be 30–35 cm (12–14 in.) long, with an internal diameter of about 0.3 cm (1/8 in.). The earpieces of the stethoscope should fit comfortably into the nurse’s ears, facing forward. The amplifier of the stethoscope is placed firmly but lightly against the patient’s skin. If the patient has excessive body hair, it may be necessary to dampen the hairs with a moist cloth so that they will lie flat against the skin and not interfere with clear sound transmission.

Auscultated sounds are described according to their pitch, intensity, duration, and quality. The **pitch** is the frequency of the vibrations (the number of vibrations per second). Low-pitched sounds, such as some heart sounds, have fewer vibrations per second than high-pitched sounds, such as bronchial sounds. The **intensity** (amplitude) refers to the loudness or softness of a sound. Some body sounds are loud, such as bronchial sounds heard from the trachea; others are soft, such as normal breath sounds heard in the lungs. The **duration** of a sound is its length (long or short). The **quality** of sound is a subjective description of a sound, such as whistling, gurgling, or snapping.

Equipment

The physical examination requires use of common health-care tools such as the stethoscope, penlight, gloves, or water-soluble lubricant. The nurse determines what equipment will be required for the specific examination to be performed and collects the supplies in advance to avoid extending the time required of the patient. The nurse should warm up cold equipment that will touch the patient’s skin. All equipment should be cleaned after each use according to the recommendations for each instrument. **Table 34-8 »** describes some of the most commonly used tools.

TABLE 34-7 Percussion Sounds and Tones

Sound	Intensity	Pitch	Duration	Quality	Example of Location
Flatness	Soft	High	Short	Extremely dull	Muscle, bone
Dullness	Medium	Medium	Moderate	Thudlike	Liver, heart
Resonance	Loud	Low	Long	Hollow	Normal lung
Hyperresonance	Very loud	Very low	Very long	Booming	Emphysematous lung
Tympany	Loud	High (distinguished mainly by musical timbre)	Moderate	Musical	Stomach filled with gas (air)

TABLE 34–8 Tools Used for a Health Examination

Supplies		Purpose
Stethoscope		To listen to heart sounds
Sphygmomanometer		To take blood pressure readings
Oximeter		To determine oxygen saturation concentration of circulating blood
Flashlight or penlight		To assist viewing of the pharynx and cervix or to determine the reactions of the pupils of the eye
Nasal speculum		To permit visualization of the lower and middle turbinates; usually, a penlight is used for illumination
Ophthalmoscope		A lighted instrument to visualize the interior of the eye
Otoscope		A lighted instrument to visualize the eardrum and external auditory canal (a nasal speculum may be attached to the otoscope to inspect the nasal cavities)
Percussion (reflex) hammer		An instrument with a rubber head to test reflexes
Tuning fork		A two-pronged metal instrument used to test hearing acuity and vibratory sense
Vaginal speculum		To assess the cervix and the vagina
Cotton applicators		To obtain specimens

(continued on next page)

TABLE 34–8 Tools Used for a Health Examination (*continued*)

Supplies		Purpose
Gloves		To protect the nurse and the patient
Lubricant		To ease insertion of instruments (e.g., vaginal speculum)
Tongue blades (depressors)		To depress the tongue during assessment of the mouth and pharynx

Clinical Example B

Clara and Roberto Galvez carry their screaming 7-year-old son Johnnie into the emergency department. They tell the triage nurse that Johnnie woke up before dawn complaining that his stomach hurt. He then vomited, and when touched, he felt very hot and sweaty. He now holds both hands tightly on his abdomen and cannot be consoled.

The nurse conducts a physical examination that reveals the following: symmetrical abdomen, bowel sounds in all quadrants, tender to palpation in the lower quadrants, guarding. Johnnie has an oral temperature of 101.5°F, pulse of 122 bpm, and respiratory rate of 24/min.

Critical Thinking Questions

1. Classify the findings as objective or subjective data.
2. Prepare a narrative nursing note from the data.
3. What factors must be considered in conducting the comprehensive health assessment of Johnnie Galvez? What additional information might prove useful in the assessment? How would you gather that information?
4. Before developing a nursing diagnosis, what must the nurse do?

Organizing Data

Collected data must be recorded at the time of collection or shortly thereafter. Data are recorded in written or digital formats that organize assessment data systematically. Most schools of nursing and healthcare agencies have developed their own structured assessment formats. Many of these are based on selected nursing models or frameworks. The format may be modified according to the patient's physical status, such as one focused on musculoskeletal data for orthopedic patients. One example of a format used to document findings from an assessment uses the mnemonic **OLD CART & ICE**. For example, for a patient with a cough that is keeping her awake at night, the findings might look like:

Onset: 10 days ago

Location: Tickle begins in throat

Duration: Daily; coughing fits become worse at night

Characteristics: Painful to cough; can't catch breath. Clear mucus coughed up

Aggravating factors: Worse at night when lying in bed

Relieving factors: Hot liquids, steamy showers

Treatment: Acetaminophen and expectorant

Impact on ADLs: Not had a good night of sleep for over a week; asked other family members to shop and clean

Coping strategies: Afternoon naps

Emotional response: Since the patient has not become better over time, she worries her condition is much more serious than usual cough.

See the exemplar on Documentation in the module on Communication for more detailed information on recording data.

Maslow's Hierarchy of Needs

Maslow's hierarchy of needs can be used to organize data (see the module on Clinical Decision Making and the module on Stress and Coping for more information about Maslow's hierarchy). Such data clusters would pertain to the following:

- Physiological needs (survival needs)
- Safety and security needs
- Love and belonging needs
- Self-esteem needs
- Self-actualization needs.

Developmental Theories

Several physical, psychosocial, cognitive, and moral developmental theories may be used by the nurse in specific situations (see the module on Development). Examples include the following:

- Havighurst's age periods and developmental tasks
- Freud's five stages of development
- Erikson's eight stages of development
- Piaget's phases of cognitive development
- Kohlberg's stages of moral development.

Functional Health Patterns and Body Systems

Assessment data can be organized according to one of several models. Most nursing programs develop their own framework for nursing assessment data based on these

models. One example is to use 11 functional health patterns to organize the data by patterns (Gordon, 2014):

1. Health perception–health management pattern
2. Nutritional-metabolic pattern
3. Elimination pattern
4. Activity-exercise pattern
5. Sleep-rest pattern
6. Cognitive-perceptual pattern
7. Self-perception/self-concept pattern
8. Role-relationship pattern
9. Sexuality-reproductive pattern
10. Coping/stress-tolerance pattern
11. Value-belief pattern.

Assessment data may also be organized by body systems (see the exemplar on the Nursing Process in the module on Clinical Decision Making), such as:

1. Immune system
2. Respiratory system
3. Cardiovascular system
4. Nervous system
5. Musculoskeletal system
6. Gastrointestinal system
7. Genitourinary system
8. Reproductive system.

Once data have been organized, they are validated.

Validating Data

The information gathered during the assessment phase must be complete, factual, and accurate because the nursing diagnoses and interventions are based on this information. **Validation** is the act of double-checking or verifying data to confirm that they are accurate and factual. Validating data helps the nurse do the following:

- Ensure that assessment information is complete.
- Ensure that objective and related subjective data agree.
- Obtain additional information that may have been overlooked.
- Differentiate between cues and inferences.
- Avoid jumping to conclusions and focusing in the wrong direction to identify problems.

To collect data accurately, nurses need to be aware of their own biases, values, and beliefs and to separate fact from inference, interpretation, and assumption. For example, a nurse seeing a man holding his arm to his chest might assume that he is experiencing chest pain when in fact it is his hand that hurts.

Not all data require validation. For example, height, weight, birth date, and most laboratory studies that can be measured with an accurate scale can be accepted as factual. As a rule, the nurse validates data when discrepancies arise between data obtained in the nursing interview (subjective data) and the physical examination (objective data) or when the patient's statements differ at different times in the assessment. Failure to validate can lead to an inaccurate or incomplete nursing assessment and could compromise patient safety. Guidelines for validating data are shown in

TABLE 34–9 Validating Assessment Data

Guideline	Example
Compare subjective and objective data to verify the patient's statements with observations made.	Patient's perception of "feeling hot" needs to be compared with measurement of the body temperature.
Clarify any ambiguous or vague statements.	<i>Patient:</i> "I've felt sick off and on for 6 weeks." <i>Nurse:</i> "Describe what your sickness is like. Tell me what you mean by 'off and on.'"
Be sure assessment data consist of cues and not inferences.	<i>Observation:</i> Dry skin and reduced tissue turgor. <i>Inference:</i> Dehydration. <i>Action:</i> Collect additional data that are needed to make the inference in the diagnosing phase. For example, determine the patient's fluid intake, amount and appearance of urine, and blood pressure.
Double-check data that are extremely abnormal.	<i>Observation:</i> A resting pulse of 30 beats per minute or a blood pressure of 210/95 mmHg. <i>Action:</i> Repeat the measurement. Use another piece of equipment as needed to confirm abnormalities, or ask someone else to collect the same data.
Determine the presence of factors that may interfere with accurate measurement.	A crying infant will have an abnormal respiratory rate and will need quieting before accurate assessment can be made.
Use references (textbooks, journals, research reports) to explain phenomena.	A nurse considers tiny purple or bluish black swollen areas under the tongue of an older patient to be abnormal until the nurse reads about physical changes of aging. Such varicosities are common.

Table 34–9 >>. Once data have been collected, organized, and validated, they can be analyzed to determine priorities for patient care.

Interpreting Data

Interpreting findings requires making determinations about all of the data collected in the health assessment process. The nurse must determine the following:

- Whether the findings fall within normal and expected ranges in relation to the patient's age, gender, and race
- The significance of the findings in relation to the patient's health status and immediate and long-range health-related needs.

Interpretation of findings is influenced by the ability to obtain, recall, and apply knowledge; to communicate effectively; and to take into account family history and dynamics. Other relevant influences include developmental, psychologic and environmental, cultural and diversity, and environmental factors.

Knowledge

Nurses obtain, recall, and apply knowledge from physical and social sciences, nursing theory, and all areas of research that affect current nursing practice. That knowledge includes human anatomy and physiology, growth and development

across the lifespan, and characteristics specific to gender and race. Knowledge also reflects health-related and healthcare trends in groups and populations, such as the increased incidence of risk factors or actual illnesses in certain groups or populations. For example, in the United States one trend is the increased incidence of obesity in children and adults.

Nurses must be able to access and use reliable resources when interpreting findings. Resources include research; scientific literature; and charts, scales, and graphs to indicate ranges of norms and expectations about physical and psychologic development. Examples of the latter include Denver Developmental scores, mental status examinations, weight, body mass index, and growth charts prepared by centers for health statistics (D'Amico & Barbarito, 2015). In addition, the nurse must be able to communicate effectively, to think critically, to recognize and act on patient cues, to incorporate a holistic perspective, and to determine the significance of data in meeting immediate and long-term patient needs. The nurse must be able to recognize situations that require immediate attention, initiate care, and seek appropriate assistance.

Expectations about interpretation of findings change as the nurse gains skills and experience in nursing practice and with advanced practice education. A nursing student is expected to recall and apply knowledge to discriminate between normal and abnormal findings and use resources to understand the findings in relation to wellness or illness for a particular patient. For example, consider the findings from the assessment of Julie Connor, a 12-year-old girl: asymmetrical shoulders and elevated right scapula on inspection of the posterior thorax, and right lateral curvature of the thoracic spine on palpation of vertebrae. Normally, scapulae should be symmetrical and the vertebrae should be aligned. The findings are interpreted as a deviation from the normal. They do not, however, give sufficient information for the purposes of making nursing diagnoses. The nurse must collect more data to make diagnoses and design a plan of care for Julie.

The nurse gains confidence and ability to discriminate between normal and abnormal findings through experience and continuing education. With such experience, the nurse will learn to recognize patterns that predispose individuals to illness or are indicative of specific illnesses, and implement and evaluate appropriate nursing care.

Clinical Example C

James Long is a 46-year-old African American man: height 5'9", weight 220 lb, BP 156/94 mmHg. His mother died at age 62 from cerebrovascular accident (stroke), and his father died at age 42 from myocardial infarction (heart attack). Using knowledge of normal ranges of findings for vital signs, height, and weight, the nurse interprets Mr. Long's BP and weight results as abnormal findings: They indicate that he has high blood pressure and is obese. The nurse applies knowledge of trends associated with health problems to interpret the significance of the findings for this patient. The nurse knows that hypertension occurs more frequently in African American males than in Caucasians. Hypertension, obesity, and a family history of coronary artery disease increase the risk of acquiring both hypertension and its associated complications. By combining knowledge of risk factors and complications with the findings themselves, the nurse working with Mr. Long can develop a plan of care. The nurse

can collaborate with other healthcare professionals to address Mr. Long's need to reduce his weight and lower his blood pressure.

Critical Thinking Questions

1. What nursing diagnoses would be appropriate?
2. What patient outcomes would you plan for Mr. Long?
3. What resources are available in your community to assist you with intervening or advocating for patients such as Mr. Long?

Communication

Effective communication is essential to the assessment process. **Communication** refers to the exchange of information, feelings, thoughts, and ideas. Verbal techniques, such as open-ended or closed questions, statements, clarification, and rephrasing, are just a few of the techniques used to gather information. The communication techniques must incorporate regard for the individual in relation to the purposes of the data collection, the patient's age, and the patient's level of anxiety. In addition, the nurse must use techniques that accommodate language differences or difficulties, cultural influences, cognitive ability, affect, demeanor, and special needs. Communication is discussed in greater detail in the module on Communication.

Developmental Factors

The patient's developmental level affects the health assessment. Sources of information may vary depending on the patient's age and ability to communicate his or her symptoms. For patients with disabilities, findings must be interpreted according to the assessed developmental level, not the patient's age. Parents or guardians are the primary sources for information about children and patients with disabilities or impairments that affect their ability to communicate. The developmental level of the patient also influences the approach to assessment, including the words and terminology. For example, assessment of a pregnant adolescent would be different from assessment of a 38-year-old woman who is pregnant for the third time. Such differences are highlighted in the module on Development.

Psychologic and Emotional Factors

Psychologic and emotional factors affect physiologic health and must be considered as predisposing or contributing factors when interpreting findings from a health assessment. For example, anxiety triggers an autonomic response, resulting in increased pulse and blood pressure. Conversely, physical problems can affect emotional health, as when childhood obesity leads to problems with self-esteem and affects socialization and development. Psychologic problems such as anxiety and depression may interfere with the patient's ability to fully participate in health assessment. Grieving may limit a patient's ability to carry out required health practices or recognize health problems. See the module on Stress and Coping for more examples of how psychologic and emotional factors play a role in health.

SAFETY ALERT A simple statement such as, "I am required by law to ask you, are you safe at home? Do you feel safe in your relationship?" may be sufficient to ascertain whether or not the patient is at risk at home or in his primary relationship. The U.S.

Preventive Services Task Force (2013) recommends that question be asked of women of childbearing age and older or vulnerable adults. Similarly, consistent with the Joint Commission's National Patient Safety Goals, suicide screening at admission may be necessary or recommended for many patients. The question, "Do you have or have you had any thought of harming yourself or others? If so, do you have a plan?" provides the opportunity to begin assessing the patient's risk for harming self or others (The Joint Commission, 2016). A third type of screening, for depression, is recommended for routine use, but especially for pregnant and postpartum women (Siu et al., 2016).

Family History and Dynamics

The nurse must consider family history of illness or health problems when conducting a health assessment and interpreting findings. Individuals with a family history of some illnesses are considered at high risk for contracting those diseases. For example, having a first-degree relative (mother, sister, or daughter) with breast cancer about doubles a woman's risk of developing breast cancer herself (American Cancer Society, 2016). The nurse must recognize that family dynamics may influence one's approach to healthcare. In some families, health-related decisions are not made independently, but rather are made by the family leader or arrived at by group consensus. Circumstances within families can affect both physical and emotional health and must be considered as part of any health assessment. For example, children of people with alcoholism are not only at risk for alcoholism, but are also at risk for emotional issues not encountered by other children. Therefore, the nurse must view and interpret unexpected physical or emotional behaviors in relation to the alcoholic family situation. The module on Family considers the concept of Family in a more complete manner.

Cultural Factors

The nurse must consider cultural factors when collecting data and interpreting findings. Culture affects language, expression, emotional and physical well-being, and health practices. Findings regarding physical and emotional health must be interpreted in relation to the cultural norms for the patient. For example, many Asian cultures would not consider lack of eye contact during the interview as a lack of ability to interact, depression, or a problem with attention. The nurse must take care to provide clear explanations of abnormal findings, illnesses, and treatments because views of illness, causality, and treatment may be influenced by a patient's culture. Refer to the module on Culture and Diversity for more information on cultural considerations.

Environmental Factors

Internal and external environmental factors affect health assessment and interpretation of findings. The nurse must always consider data in relation to norms and expectation for age, race, and gender and in relation to factors affecting the individual patient.

Data from the comprehensive health assessment provide clues about the patient's internal environment, including emotional state, response to medication and treatment, and physiologic or anatomic alterations that influence findings and interpretations.

External environmental factors can also affect health, health assessment, and interpretation of findings. External factors may include any of the following:

- Inhaled toxins such as smoke, chemicals, and fumes
- Irritants that can be inhaled, ingested, or absorbed through the skin
- Noise, light, and motion
- Objects or substances encountered in the home, school, or workplace, such as animal dander or dust.

For more information about the external environmental factors themselves, consult the module on Safety. To become knowledgeable about nurses' exciting roles in making changes in the current environment, refer to the exemplar on Environmental Quality in the module on Advocacy.

Concepts Related to Assessment

Nursing care always begins with assessment. Nursing care depends on a strong knowledge base and the application of critical thinking. Regardless of the clinical setting, the role of the nurse is multifaceted. Each situation requires the nurse to use the nursing process, starting with strong assessment skills.

In the biophysical realm, thorough nursing assessment (including the fifth vital sign of pain) allows the nurse to identify an individual's problems with acid-base balance, cellular regulation, comfort, digestion, elimination, and fluids and electrolytes. Illness and injury will leave evidence that can be discovered through assessment.

In the psychosocial realm, a similarly thorough nursing assessment can point out a patient's difficulties with trauma, addiction, cognition, grief and loss, mood and affect, and stress and coping. At the same time, an assessment of the patient's strengths in the areas of family and spirituality can be a good foundation on which to build better health and wellness. The Concepts Related to Assessment feature lists some, but not all, of the concepts that are integral to assessment. They are listed in alphabetical order.

Holistic Health Assessment Across the Lifespan

Nursing assessment skills help the nurse interpret how the complex interactions of heredity, environment, and physiologic, cognitive, and psychologic development affect an individual at a particular time. By developing an image of what is usual or expected of children and adults of various ages, the nurse has a basis for a comparison with the norm. This knowledge and an understanding of individual variations provide a foundation for holistic health assessments across the lifespan.

Holistic health can best be defined as a clinical mindset that considers more than the physiologic health status of a patient. Holistic health includes all factors that affect the patient's physical and emotional well-being. With a holistic approach, the nurse recognizes that developmental, psychologic, emotional, family, cultural, and environmental factors combine to affect immediate and long-term actual and potential health goals, problems, and plans.

Concepts Related to Assessment

CONCEPT	RELATIONSHIP TO ASSESSMENT	NURSING IMPLICATIONS
Legal Issues	Clinical trial enrollment opportunity → assessment of level of knowledge about risk-benefit ratio → informed consent	<ul style="list-style-type: none"> Nurse offers time and resources to answer questions about research study involvement.
Oxygenation	If assessment shows ↓ O ₂ , prioritize interventions to ↑ O ₂	<ul style="list-style-type: none"> Decrease oxygen workload by having patient rest; administer O₂ by nasal cannula if needed.
Perfusion	If assessment shows ↓ blood flow to a limb, prioritize intervention to ↑ blood flow	<ul style="list-style-type: none"> Check for clothes restricting circulation. Use physical movement and exercise to keep fit.
Professional Behaviors	Professional approach ↑ knowledgeable assessment ↑ patient confidence	<ul style="list-style-type: none"> A professional approach helps build confidence and rapport with the patient, making it more likely that the patient will be honest and cooperative during the assessment.
Thermoregulation	If assessment shows ↑ temperature, discover cause of fever	<ul style="list-style-type: none"> Increase fluids and give antipyretic medications.
Safety	If assessment of home environment shows ↑ hazards, intervene to ↓ injury risk	<ul style="list-style-type: none"> Before discharge, scan home environments for obstacles that might cause a patient to slip or fall.
Sensory Perception	If assessment of preschooler shows ↓ visual acuity → assistance device to ↑ vision	<ul style="list-style-type: none"> Refer to optometrist to measure for eyeglasses prescription.
Tissue Integrity and Mobility	If older patient in wheelchair → constant sitting → assess skin → stage 2 pressure ulcer	<ul style="list-style-type: none"> Move patient to positions that do not cause pressure on area of breakdown. Continue to ↑ padding of seat.

A comprehensive assessment includes information about physical, cognitive, and emotional growth and development, including both subjective and objective data. When conducting health assessments, the nurse must be able to obtain accurate data and interpret findings in relation to expectations and predicted norms and ranges for patients at various stages of physical and emotional development. Knowledge of anatomic and physiologic changes as well as theoretical information about cognitive, psychoanalytical, and psychosocial events and expectations at each stage of human development is invaluable for the nurse. Further information about growth and development can be found in the module on Development.

Physical growth and development change across the lifespan. Stages from infancy through adolescence are marked by spurts of rapid growth and development. Health assessment includes the use of clinical growth charts to compare individual patient measurements of height and weight (and head circumference in infants) against expected normal values for age and gender. Additional indicators for normal growth and development throughout these stages include eating, sleeping, elimination, and activity patterns. Neurologic and sensory functions are assessed by monitoring development of speech and language, muscular growth, strength and coordination, and tactile sensibility.

Puberty is a period of rapid physiologic growth and development. Puberty occurs between the ages of 10 and 14 years in girls and is marked by menarche, breast development, axillary and pubic hair growth, and a spurt in height.

In boys, puberty occurs between the ages of 12 and 16 years and is characterized by a spurt in height, development of the penis and testicles, and body hair growth (axillae, chest, facial), including pubic hair. Young adulthood is the stage marked by completed growth in physical and mental structures. Physical development continues to be assessed by comparing individual findings to clinical growth charts and by assessing eating, sleeping, and activity patterns.

Middle age, occurring between the ages of 45 and 60 years, is another period in which dramatic changes in physical development occur. Primary changes are related to hormonal changes in both men and women, resulting in menopause in women. During middle age, changes occur in all systems; these include decreases in basal metabolic rate, muscle size, nerve conduction, lung capacity, glomerular filtration, and cardiac output. The middle-aged patient experiences increased adipose tissue deposit and skeletal changes leading to decreases in height, as well as changes in tactile sensibility, vision, and hearing. The physical changes continue into the stage of older adulthood. Middle-aged and older adults are at risk for obesity and associated health problems. Health assessment includes use of the BMI measurement to assess weight and risk for disease. Assessment also includes evaluation of the ability to carry out ADLs and regular testing of vision and hearing.

The leading causes of death throughout the lifespan are outlined in **Table 34-10** >>.

In addition to expectations about physical growth and development, there are expectations about cognitive, psychosocial, and emotional development across the lifespan. For

TABLE 34-10 Leading Causes of Death Throughout the Lifespan

Age Range	Leading Causes of Death and Number of Deaths in 2014 (Rounded to Nearest Hundred)
Birth–age 4 years	<ul style="list-style-type: none"> Conditions originating in the perinatal period (short gestation, maternal pregnancy complications, placenta/cord/membranes): 6800 Congenital anomalies: 5100 Unintentional injuries: 2400 Sudden infant death syndrome (SIDS): 1500
Age 5–9 years	<ul style="list-style-type: none"> Unintentional injuries: 700 Cancer: 400 Congenital abnormalities: 200 Heart and acute/chronic lung diseases: 200 Homicide: 100
Age 10–24 years	<ul style="list-style-type: none"> Unintentional injuries: 12,600 Suicide: 5500 Homicide: 4300 Cancer: 2000 Heart and acute/chronic lung diseases: 1600

Age 65 and older	<ul style="list-style-type: none"> Heart and acute/chronic lung diseases: 659,300 Cancer: 413,900 Unintentional injuries: 48,300 Cerebrovascular disease: 113,300 Alzheimer disease: 92,600 Diabetes mellitus: 54,200

Source: Data from Centers for Disease Control and Prevention, *10 Leading Causes of Death by Age Group, United States—2014*, retrieved from http://www.cdc.gov/injury/wisqars/pdf/leading_causes_of_death_by_age_group_2014-a.pdf

example, attachment is an essential element in infant development. Attachment refers to the tie between the infant and caregivers that promotes physical and psychosocial well-being. Assessment of attachment includes observing caregivers for eye contact, apparent interest in the child, talking or cooing to the child, response to infant needs, and communication.

Children are expected to develop language and cognitive abilities that enable them to learn and become independent over time. Young adults are expected to develop relationships with others and to become productive members of society. Maturity and aging lead individuals to contribute to the well-being of communities and their families and often to adapt to change and loss. Developmental milestones and crises occur in all stages of development and must be noted during assessment. A variety of instruments and scales can be used to identify developmental delays, behavioral patterns, and responses that indicate potential or actual problems with emotional, cognitive, and psychosocial development and adaptation in children and adults. **Table 34-11** » includes a list and description of

TABLE 34-11 Instruments to Assess Growth and Development in Infants and Children

Instrument	Description
Ages & Stages Questionnaire (ASQ)	The ASQ is a parent questionnaire that covers developmental areas of communication, gross motor, fine motor, problem solving, and personal-social in children.
Battelle Developmental Inventory	This inventory tests developmental domains of cognition, motor, self-help, language, and social skills in children from birth through 8 years of age.
Brigance Screens	These screens assess speech–language, motor, readiness, and general knowledge at younger ages and also reading and math. Used from 21 to 90 months of age.
Child Development Inventory	Scales used to measure social, self-help, gross motor, fine motor, expressive language, language comprehension, letters, numbers, and general development in children from 15 months to 6 years of age.
Denver II	Screening test administered to well children between birth and 6 years of age. It is designed to test 20 simple tasks and items in four sectors: personal-social, fine motor adaptive, language, and gross motor.
Hassles and Uplifts Scale	Scale used to measure adult attitudes about daily situations defined as “hassles” and “uplifts.” It focuses on evaluation of positive and negative events in daily life rather than on life events.
Life Experiences Survey	This self-administered questionnaire reviews life-changing events of a given year. Ratings are used to evaluate the level of stress an individual is experiencing.
McCarthy Scale of Children’s Abilities	The McCarthy scale evaluates the general intelligence level of children age 2½–8½ years. The scale identifies strengths and weaknesses in verbal, perceptual-performance, quantitative, memory, motor, and general cognitive skills.
Pediatric Symptom Checklist	Checklist of short statements used to identify conduct behaviors and behaviors associated with depression, anxiety, and adjustment in children age 4–16 years. Item patterns determine the need for behavioral or mental health referrals.
Stanford-Binet Intelligence Scale: Fourth Edition	The Stanford-Binet test measures general intelligence. The areas of verbal reasoning, quantitative reasoning, abstract/visual reasoning, and short-term memory can be tested from age 2 to 23 years.
Wechsler Preschool and Primary Scale of Intelligence—Revised (WPPSI-R)	The WPPSI-R is a standardized test of language and perception for children age 4½–6 years.

some of the instruments available to measure aspects of growth and development.

Assessment of Infants, Children, and Adolescents

Children are not “little adults.” Significant differences exist among infants, children, adolescents, and adults. These differences include variations in physiology, development, and

cognition that must be incorporated into the nursing assessment. For instance, the head-to-toe approach to physical assessment is useful in many situations and with different types of patients, but it may not work with young children. Adults and adolescents will usually sit on an examination table, wear a paper gown, and follow the nurse's instructions. However, infants and toddlers often refuse to sit still or cooperate.

Furthermore, young children do not have the cognitive or verbal ability to describe symptoms or comply with complex instructions. The nurse must possess strong assessment skills to overcome the communication and situational challenges involved in pediatric physical assessment.

In assessing children, it may be helpful to conduct the nutrition history portion before the physical assessment in order to establish rapport and make the child more comfortable with the process. Rapport is essential, especially when assessing an adolescent. Infants and younger children need a caregiver present to assist with the assessment and to answer questions (**Figure 34-7** >>). Adolescents may be more comfortable having privacy during an assessment. The nurse may discuss the assessment arrangement with the adolescent and caregiver separately to allow the adolescent to give an unpressured answer. A caregiver can be interviewed separately if appropriate.

The parameters of the physical assessment in children include anthropometric measurements and clinical observations appropriate for each child's age. Determination of developmental milestones provides critical information and is part of a complete assessment. Developmental milestones are covered in the module on Development.

Anthropometric measurements in children should be obtained using equipment appropriate for the pediatric population. Recumbent length and weight measurements are needed for infants and young children. An infant's or toddler's weight should be measured without the child wearing a diaper. Older children can have their height and weight measured while standing. Skinfold measurements should be done using calipers calibrated to 0.2 mm because small changes in measurement can cause changes in assessment classification. The World Health Organization (WHO)

recommends weight for height as the standard in measuring children because skinfold and circumference measurements are prone to errors that could result in misclassification of nutritional health. Head circumference is a measurement unique to the assessment of growth in children at or under 3 years of age. Beyond age 3, head circumference is not a valid tool for assessing growth and nutritional status.

Anthropometric measurements have age-specific references established by the Centers for Disease Control and Prevention and WHO. In children under 20 years of age, references are described using charts with age-specific percentiles for height, weight, body mass index (BMI), and, for children under 36 months, head circumference. Percentiles are used to assess growth rate and health. Percentile charts are derived from the distribution of data from population studies and are age- and gender-specific descriptions of anthropometric measurements. The charts may change as new data are incorporated. For example, breastfed infants normally grow at a slightly slower rate than do formula-fed babies, and newer infant growth charts are more representative of the population-matched prevalence of breastfed infants compared to charts published before 2000.

Infants, children, and adolescents can be compared to their age-matched peers to determine their individual percentile within the population. A best use of percentile charts is in monitoring individual growth over time. Normally, children will remain within a narrow percentile range for each measurement over the course of childhood. For example, a child assessed sequentially in the 25th percentile for height (length) for age may have a small frame and parents with small stature and may not be at risk for poor nutritional health. However, a child sequentially in the 50th percentile for height for age who drops to the 25th percentile may be at risk for undernutrition. A significant drop or increase in percentile category is cause for further investigation to assess for undernutrition or overnutrition. Overweight and obesity (overnutrition) in children is defined as a BMI for age greater than the 85th percentile and the 95th percentile, respectively. Undernutrition is defined as a BMI for age less than the 5th percentile. Separate growth references exist for children with some chronic diseases and for knee-height estimates of stature. See the module on Nutrition for more information on overnutrition and undernutrition.

Children are physically different from adults. Each concept in the individual domain (Modules 1–33) discusses lifespan differences that can be anticipated when conducting the physical examination.

The nurse should use a caring, supportive, yet firm approach with children. Whenever possible, play should be incorporated into the assessment process. It is helpful to allow children to touch and manipulate equipment. Adhesive bandages or empty syringes can be provided for play-acting with dolls. The nurse should encourage children to talk about their fears and concerns. Painful procedures should not be performed while a child is seated on a parent's lap. Children need to know they are safe from painful experiences when they are with their parents.

When a child is ill, parents experience increased stress that results from interrupted sleep, concern for the child's well-being, and frustration at the inability to understand what is hurting or bothering their child. Each of these factors

Source: Ruslan Dashinsky/E+/Getty Images.

Figure 34-7 >> This mother holds her baby while the nurse performs an examination.

may affect a parent's ability to recall information or to follow complex instructions. The nurse can help parents by providing them with written instructions as appropriate and encouraging patients and families to journal about their experiences or keep a notebook with information and details about the child's illness and treatment, including nutrition and activity levels. The nurse should consider parental stress levels when developing care plans.

The basic components of a health history are the same whether the nurse works with children or adults. However, a number of variations must be incorporated into a pediatric health history. It is essential for the nurse to determine the relationship between the child who seeks healthcare and the adult who presents with the child. State law determines which individuals can legally consent to medical treatment of a minor child. Federal privacy laws limit access to protected health information. One must never assume legal or family ties between children and the adults who accompany them. Nannies, babysitters, friends, siblings, and stepparents often transport children to healthcare appointments. Asking directly about the relationships is the easiest way to ensure compliance with the legal and ethical concerns regarding the medical treatment of children.

Many children are nonverbal or have limited language ability; therefore, the nurse depends on parents and guardians for health history information. This can limit the specificity of the history information. However, it is important to ask preschoolers and older children about their chief complaint and symptoms even though the information they provide may not be as detailed as the information provided by their parents or guardians.

Prior to the health interview, the nurse should determine whether the parent is stressed or distracted. Many parents of ill children are sleep deprived because of their child's altered sleep patterns. Sleep deprivation can result in altered recall, limited ability to follow complex questions, and diminished ability to remember verbal instructions. The presence of other children can be distracting, especially if the children are loud, active, or irritable. The nurse can distract energetic or fussy children with books, crayons, or toys.

The nurse should listen carefully to the parent or primary caregiver and use open-ended questions to elicit health information. Parents know their children better than anyone else. They are able to detect subtle differences in their child's behavior. It is essential to pay special attention to the chief complaints that parents describe. A thorough physical assessment is then conducted based on the issues and concerns raised in the health history.

The nurse should call the child by his or her name and use words that the child understands. For example, most preadolescents are not familiar with the word *abdomen*, but most children have used the word *tummy* or *belly* from infancy (**Figure 34-8**)). Instead of asking "Does your head hurt?" the nurse should ask the child to touch the head where it hurts. It is necessary to be patient. Children often pause between words or repeat phrases when they are excited or nervous.

The nurse should give children who are at least 10 years old the option of being examined without their parents or other accompanying adult present. The patient is the child, not the parent. The nurse's legal and ethical responsibility is

Source: Jessica Lewis/Moment/Getty Images.

Figure 34-8 » This toddler knows that his belly hurts, but he would not understand if the nurse asked him if his abdomen hurt.

to the child first. The nurse must respect the confidentiality of the information provided by older children and be aware of state and federal laws regarding parental notification and mandatory reporting. The parent and the child should be told what the nurse can and cannot keep confidential. For example, statements such as "What you and I talk about will be between the two of us, unless you tell me that you are thinking about harming yourself or someone else, or if you tell me that someone is hurting you" help establish rapport and boundaries to the nurse-child and nurse-parent relationship. If a nurse is required to report health interview information to others (e.g., public health departments or child protective service agents), the nurse should always inform the child of the need to share the information with others prior to actually doing so. Failure to do so can jeopardize the rapport between nurse and child. Additional tips for effective assessment of pediatric patients are given in **Box 34-4** ».

Assessment of Newborns

The assessment of newborns is covered in Module 33, Reproduction, in the exemplar on Newborn Care.

Assessment of Infants

Frequent assessments during the first year provide opportunities to monitor the infant's rate of growth and development as well as to compare the infant with the norm for age. Height, weight, and head circumference measurements are plotted on an appropriate growth chart at each assessment. The three measurements should fall within two standard deviations of each other. More importantly, each measurement should follow the expected rate of growth, following the same percentile throughout infancy.

Accurate assessment combining information obtained by history, physical assessment, and knowledgeable observation allows early identification of common problems that may easily be resolved with early intervention. Often basic parent education and support remedy problems that, if left untreated, could later result in significant health problems or disturbed parent-child interactions.

Overnutrition and undernutrition are identified by weight that crosses percentiles. In **overnutrition**, the rate of

Box 34–4

Tips for Effective Assessment of the Pediatric Patient

- Protect the modesty and privacy of children, just as you would for adults. Use standard precautions to examine children, just as you would for adults.
- Explain procedures and techniques in words that children can understand.
- Remember that young children are more comfortable and compliant when they sit on their parents' laps. However, avoid this location when performing painful activities.
- Establish rapport with the parent and child before initiating any physical examination.
- Begin with the least threatening examinations; a flexible approach to assessment is essential.
- Perform painful or invasive procedures at the end of the assessment.
- Encourage young children to take deep breaths by having them blow bubbles or blow out the light on the otoscope.
- Allow children to touch equipment (**Figure 34–9** ►). Use playful language to talk about examinations, such as asking children if they have elephants in their ears, before examining the tympanic membrane.
- Use toys, for example, finger puppets, as distractions.
- Use standard precautions.

Source: Ariel Skelley/Blend Images/Getty Images.

Figure 34–9 ► A nurse allows her young patient to play with her stethoscope before using it to assess the child's heart.

weight gain is accelerated; in **undernutrition** the rate of weight gain diminishes. Overnutrition may occur when caregivers do not learn to read infants' cues but instead assume that every cry signals hunger. Cultural beliefs that a plump baby is a healthy baby may also lead parents and other caregivers to overfeed infants.

Undernutrition may be caused by inadequate caloric intake. This may result from lack of knowledge of normal infant feeding, a lack of financial resources to obtain formula, or inappropriate mixing of formula. Some quiet or passive infants do not demand feedings, and parents or caregivers may misinterpret this passivity as lack of hunger.

Head growth that crosses percentiles requires evaluation, because it may indicate **hydrocephalus** (enlargement of the head caused by inadequate drainage of cerebrospinal fluid). Early diagnosis and intervention for rapid head growth prevent or diminish serious neurologic effects.

Parents and caregivers generally enjoy relaying infants' new developmental milestones and can accurately describe infants' abilities. An infant who seems to be lagging behind on milestones may not be receiving appropriate stimulation. Assessment of caregivers' expectations and knowledge of infant development may reveal a knowledge deficit. Suggesting specific activities for caregivers to do with their infants may be the only intervention required. Infants who continue to lag significantly behind and are not achieving normal milestones require evaluation.

Healthy attachment is observed as a caregiver holds an infant close in a manner that encourages eye contact (the *en face* position). The caregiver looks at the infant, smiles, talks, and interacts with the infant. The infant responds by fixing on the caregiver's face, smiling, and cooing. The caregiver stays close to the infant, providing support and reassurance during examinations or procedures.

Failure to engage the infant through eye contact, talking, or a smile limits available opportunities for the caregiver to receive positive feedback from the infant. The infant, in turn, finds efforts to engage the parent frustrating, resulting in decreased attempts to interact. A negative pattern is quickly established, requiring more extensive intervention the longer it persists.

Assessment of Toddlers

Although the rate of growth of toddlers decreases, it proceeds in an expected manner. Height and weight continue to follow a percentile, although slight variations are often seen. Assessing caloric intake by obtaining a 24-hour recall provides clues to inappropriate feeding patterns. Toddlers generally feed themselves and begin to interact with the family at meals. A favorite food one week may be refused the next, causing frustration and confusion in caregivers. Concern for the toddler's health may precipitate a power struggle as parents try to force the toddler to eat. Poor weight gain may result as the toddler exerts a newfound independence by refusing to eat. Excessive weight gain occurs when caregivers use food to quiet or bribe their toddlers. Discussing appropriate eating expectations and weight gain helps parents resolve eating problems.

Because the young toddler is unlikely to cooperate, a health history is often the best way to assess development. Older toddlers are more willing to play with developmental testing materials or explore the environment while in proximity to a caregiver, enabling direct observations of development. Because toddlers might not speak in a strange or threatening environment, language assessment can be difficult. Listening to the child talk in a playroom or waiting room increases the probability of assessing the toddler's language.

The toddler wanders a short distance from a caregiver to explore, returning periodically to "touch base." After

receiving reassurance and encouragement, the child is ready for further exploration. Exploration provides learning opportunities but also places the toddler at risk for accidental injury or poisoning.

Toddlers have frequent tantrums, usually in response to unwanted limits or frustration. An attitude of calm understanding limits the duration of tantrums and keeps tantrums from becoming power struggles or attention-getting behavior.

Toddlers quickly turn to caregivers for comfort or when confronted with a stranger. Observing the adult-child interaction and listening to how the adult speaks to the child provide information about the quality of the relationship.

Continuous clinging of a toddler to a caregiver in a non-threatening situation is unusual. Failure of the child to look to a caregiver for comfort and support may indicate that trust did not develop during infancy. Inappropriate caregiver expectations, such as expecting a toddler to sit quietly in a chair, may interfere with the normal progression of the toddler's development. Caregiver inattention to the child's activities and failure to set limits result in the child's inability to develop self-control.

Assessment of Preschoolers

Preschoolers are generally pleasant, cooperative, and talkative. They are often less anxious if their caregiver is in view but do not need to return to the caregiver for comfort except in threatening situations. Talking with preschoolers about favorite activities allows the nurse to assess language ability, cognitive ability, and development. The nurse evaluates the child's use of language to express thoughts, sentence structure, and vocabulary. It may be possible to identify the ability to concentrate, magical thinking, and reality imitation as the child relays play activities. Lack of appropriate environmental stimulation may become evident, and the nurse may need to educate caregivers about age-appropriate activities for their children.

Preschoolers' slowed rate of growth is often of concern to caregivers. The nurse can allay anxiety by showing the preschooler's growth chart and discussing eating expectations.

A clinging, frightened preschooler in a nonthreatening situation may indicate a child who lacks a trusting relationship with his or her immediate caregivers. Lack of communication between caregiver and child limits the child's ability to learn appropriate social interaction and to practice language skills.

Children who do not exhibit appropriate achievement of developmental milestones should receive screenings and, if indicated, appropriate interventions. Periodic health assessments are necessary to ensure child well-being and to discuss child development with parents. Table 7-4: Health Screenings and Immunization Guidelines Across the Lifespan in Module 7 on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for newborns and infants, toddlers, and preschoolers. Depending on the results of the examination, additional screenings or referrals to agencies that conduct developmental screenings may be warranted.

Assessment of School-Age Children

The slow, steady growth and changing body proportions of school-age children can make them appear thin and gangly.

Assessing children's intake of nutrients and calories and reviewing their growth charts reassure parents that their children are not too thin. By educating parents to evaluate objectively their children's diets during the early school-age years, the nurse can help relieve family stress resulting from parents pushing children to eat and can help reinforce healthy eating habits that prevent obesity. Older school-age children have an increase in appetite as they enter the prepubertal growth spurt. During the growth spurt, height and weight increase and may normally cross percentiles.

School-age children are eager to talk about their hobbies, friends, school, and accomplishments. Increasing neurologic maturity allows them to master activities requiring gross and fine motor control, such as sports, dancing, playing a musical instrument, artistic pursuits, or building things. School-age children enjoy showing off newly acquired skills, and families display pride in their children's accomplishments.

School-age children frequently sort and classify collections of rocks, sports cards, dolls, coins, stamps, or almost anything. They are industrious in school, feeling pride in their accomplishments as they master difficult concepts and skills. Families provide positive feedback and encouragement to their children and speak of their children's successes with pride.

Adult family members and school-age children communicate openly, with adults setting appropriate and much-needed limits. Although peer relationships are becoming more important, the family remains the major influence during most of the school-age years. As children approach adolescence, the relationship with family may become strained as the children are drawn closer to peer groups and seek greater independence.

Children who lack hobbies or cannot think of any accomplishments may be environmentally deprived. Caregivers who are unable to think of anything positive to say about their children or who speak of them as a burden are likely to have a disturbed parent-child relationship. Children who lack encouragement and positive reinforcement at home for their achievements are at risk for gang recruitment. Gangs provide the "family" support children lack at home, increasing children's risk for violence, drug use, and illegal activity.

Problems in school may evolve at this time, and caregivers and children may have conflicts over grades and study time. The nurse can encourage the caregiver to help the child set a consistent place and time for homework. Caregivers should also be encouraged to communicate actively with the child's teacher. Teachers, adults, family members, and healthcare providers may identify learning disabilities at this time by careful observation.

Table 7-4: Health Screenings and Immunization Guidelines Across the Lifespan in Module 7 on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for school-age children.

Assessment of Adolescents

Parents and caregivers rarely express concern that their adolescents are not eating. The pubertal growth spurt requires adolescents to increase their caloric intake dramatically, causing parents concern that the adolescent eats constantly but never seems full. Despite this, adolescents

(particularly women) are at risk for developing eating disorders. Information about eating disorders is included in the module on Self.

Adolescents often communicate better with peers and adults outside of the family than with family members. Assessing adolescents with their parents and then one-on-one affords a more complete picture of the adolescent–parent relationship and provides adolescents with an opportunity to express themselves and discuss concerns freely.

Most adolescents are able to hold an adult conversation and are often happy to discuss school, friends, activities, and plans for the future. They tend to be anxious about their bodies and the rapid changes that they are experiencing. Often adolescents are unsure if what is happening to them is normal, and they frequently express somatic complaints.

As adolescents become more independent, adult family members become anxious over their evolving lack of control. Parents may be uncomfortable with adolescents' sexuality, rebellious dress and hairstyles, and developing values that may differ from those of the parents. Communication between parents and adolescents is often challenging at this stage.

Severely restricting the activities and freedom of adolescents inhibits their ability to progress toward independence. Adolescents who lack social contacts and spend much time alone may be depressed and at high risk for suicide. Acting out and risk-taking behaviors place adolescents at risk for serious injury from accidents or drug or alcohol use. Alliance with gangs places adolescents at risk for violence and participation in illegal activities.

Table 7–4, Recommended Health Promotion Activities from Birth to Adolescence, in the module on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for the newborn period through adolescence.

Assessment of Pregnant Women

Prenatal care is important to ensure the health of both the developing fetus and the mother. Briefly, the changes that need to be assessed for comparison with normal expectations result from hormonal influences, the growing fetus, and the mother's physiologic and psychologic adaptation to the fact of being with child (**Figure 34–10** »). Every system in the pregnant woman's body must adapt to support a new life and, at the same time, maintain the mother's body functions within normal limits.

The system changes include those in the reproductive system, including the uterus, cervix, ovaries, and vagina. Changes also happen in the breast, to prepare for possible lactation. The respiratory and cardiovascular systems change dramatically. Both need to support two individuals. The volume of air breathed increases 30 to 40%. Cardiac output peaks at 25 to 30 weeks' gestation at one third to one half above pre-pregnant levels.

Both the gastrointestinal system and the urinary tract prepare to provide digestion, absorption, and elimination for two individuals, instead of one. Both the musculoskeletal and central nervous systems alter their functioning only slightly to support the pregnancy. Finally, the mother's metabolism

Source: Hero Images/Getty Images.

Figure 34–10 » Prenatal checkups include a weigh-in to ensure that the mother is gaining weight appropriately.

accelerates to support the additional demands of the fetus, and the necessary preparation for labor and lactation.

The nine months of changes thoroughly affect the mother's life. Nursing assessment and education activities track the changes over time, comparing them to normal adaptations. For more in-depth details about how the mother, fetus, and obstetric-gynecologic team ensure a healthy pregnancy, see the four Assessment features in the module on Reproduction: Initial Prenatal Assessment, Subsequent Prenatal Assessment, Intrapartum Assessment during childbirth, and Postpartum Assessment after childbirth. See the module on Mood and Affect for an overview of assessment and nursing considerations related to preventing, identifying, and intervening in peripartum depression.

Assessment of Young Adults

Young adults tend to be busy, productive, and healthy. At their maximum physical potential, young adults actively pursue sports and physical fitness activities. They refine their creative talents and enjoy activities with peers.

Young adults form intimate partnerships with others in mature, cooperative relationships. Traditionally, such intimate relationships involved marriage. Increasingly, these relationships are formed and maintained without a formal marriage or between two people of the same sex. Developmentally, the important concept is the formation of the mature, intimate relationship.

People who want to have children in the 21st century have many more choices than their own parents and grandparents had: Surrogate motherhood, artificial insemination, in vitro fertilization, and other technologic innovations make it possible for couples in a variety of situations to choose to become parents. Deciding not to have children and delaying having children are increasingly accepted, as are the decisions of single women to have children and single men to adopt children.

Young adults have chosen an occupation, established their values, and adopted a lifestyle. Career advancement, a quest for financial stability, and emotional investment characterize the young adult years.

The young adult without a steady job may lack direction and self-confidence. Marital discord may trigger feelings of failure and insecurity. Failing to achieve intimacy may place the young adult at risk for depression, alcoholism, or drug abuse.

Table 7–5, Recommended Health Promotion Activities for Adults, in the module on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for young adults.

Assessment of Middle-aged Adults

Typically, the adult in the middle years of life is satisfied with past accomplishments and involved in activities outside the family. Healthy adjustment to the physical changes of aging includes developing appropriate leisure activities in preparation for an active retirement. Good financial planning during the middle adult years helps ensure financial security during retirement.

The middle adult years signal the end of childbearing and, most often, the end of childrearing. Individuals adjust to never having had children or to children leaving home. Couples may renew their relationships or find they have little in common and perhaps separate. Some women choose to delay childbearing until their late 30s or early 40s, after establishing their careers. They begin their childrearing years as many of their peers are completing this phase of life. Older mothers must make the transition from career women to mothers, even if they continue their careers.

The dissatisfied middle-aged adult is unhappy with the past and expresses little or no hope for the future. Sedentary and isolated, the individual complains about life, avoids involvement, and fails to plan appropriately for retirement.

Table 7–5, Recommended Health Promotion Activities for Adults, in the module on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for middle-aged adults.

Assessment of Older Adults

A comprehensive assessment is essential to understanding the health needs of the older adult. A comprehensive geriatric assessment should be carried out in the following circumstances:

1. Yearly for the older adult with complex health needs during the annual visit for routine health maintenance with the primary healthcare provider
2. After any abrupt change in physical, social, or psychologic function
3. When the older adult is hospitalized for acute illness or injury
4. When nursing home placement or a change in living status is being considered
5. When the older patient or the patient's family members would like a second opinion regarding an intervention or treatment protocol recommended by the primary care provider.

Because of the particular needs of older adult patients and the frequent need to work with healthcare providers in several disciplines, the nurse must be not only knowledgeable in the content area of gerontology and geriatrics, but

also educated regarding the issues of team dynamics. Essential skills in team dynamics include the following:

- An awareness of the roles and contributions of all team members
- Excellent communication skills in order to share information
- Conflict resolution skills
- The ability to see that multiple disciplines can provide information critical to solving the problems of the older patient.

Despite variations in instruments, structure of the interprofessional team, and methods employed, several strategies make the evaluation process more effective. These include the development of a close-knit interprofessional team with minimal redundancy in the assessments performed, the use of carefully designed questionnaires that reliable older patients or their caregivers can complete beforehand, and the effective use of assessment forms that are incorporated into computer databases (Kane et al., 2018).

The nurse can incorporate holistic assessment techniques and standardized instruments into routine evaluations (see **Table 34–12** » for a list of instruments used to assess older adults). In addition, the nurse is in an ideal position to advocate for older patients who would benefit from holistic assessment and to urge patients to seek the services of specialized geriatric assessment teams if these seem warranted.

» **Stay Current:** A set of more than 30 issues of *Try This: Best Practices in Nursing Care to Older Adults* is available from the Hartford Institute for Geriatric Nursing (2017), at the New York University College of Nursing. The general assessment series includes information on the purpose of the clinical measurement, the best tool, the target population, validity and reliability, strengths and limitations, and follow-up suggestions. It is available online at <https://consultgeri.org/tools/try-this-series>. Another set of geriatric assessment tools in 11 categories is available from the Iowa Geriatric Education Center (2017) at the University of Iowa. It is available online at <https://igec.uiowa.edu/>.

The three underlying principles of comprehensive geriatric assessment are as follows:

1. Physical, psychologic, and socioeconomic factors interact in complex ways to influence the health and functional status of the older individual.
2. Comprehensive evaluation of an older patient's health status requires an assessment in each of these domains. The coordinated efforts of various healthcare professionals are needed to carry out the assessment.
3. Functional abilities should be a central focus of the comprehensive evaluation. Other more traditional measures of health such as medical diagnosis, nursing diagnosis, physical examination results, and laboratory findings form the basic foundation of the assessment in order to determine overall health, well-being, and the need for social services (Kane et al., 2018).

The interrelationships among the physical, social, and psychologic aspects of aging and perhaps illness present a challenge to the nurse when beginning the geriatric evaluation. The nurse is often charged with the responsibility of

TABLE 34–12 Instruments for Evaluation of Older Adults

Instrument	Focus	Measurement	Uses
Tilburg or Groningen Frailty Indicators	Loss of resources causes inability to respond to physical or psychologic stress	Either professional or self-report of functioning in four domains: physical, cognitive, social, psychologic	Vulnerability to future poor health outcomes; to predict disability, healthcare use, and quality of life
World Health Organization Quality of Life questionnaire (WHOQOL-BREF)	Individual's perceptions of culture and value systems, and personal goals, standards, and concerns	Brief version is 26 items measuring four domains: physical health, psychologic health, social relationships, and environment	Can be used for people with intact cognitive functioning as well as mild-to-moderate dementia
Short Portable Mental Status	Mental process of knowing and understanding	Ten questions, can adjust for educational level	Assess cognitive functioning; can be repeated to check if decline in cognition
Mini-Mental State Examination (MMSE)	This brief, quantitative measure of cognitive status in adults can be used to screen for cognitive impairment, to estimate the severity of cognitive impairment at a given point in time, to follow the course of cognitive changes in an individual over time, and to document an individual's response to treatment. It is used frequently to track cognitive changes in patients with dementia	Eleven questions that assess areas such as orientation, recall, attention, and language	Assess cognitive functioning; can be repeated to check if decline in cognition
Katz's ADL Scale	Ability to independently bathe, dress, toilet, transfer, be continent, feed	Six yes/no questions, one for each functional area	Rate performance of independent activity
Instrumental Activities of Daily Living (IADLs)	Completion of complex activities; need for support services	Measures eight complex activities needed for independent functioning, assessing how much assistance is required, if any	If patient is not able to perform IADLs, assistance will be needed. If caregiver support is inadequate, a change in living situation might be indicated
Geriatric Depression Scale	Low mood accompanied by low self-esteem and loss of interest or pleasure in normally enjoyable activities	Short form has 15 yes/no questions, completion in 5 minutes; original form had 30 questions	Used to evaluate depression, which can exist alone or accompany dementia, as well as major illnesses: recent stroke, coronary artery bypass graft, or myocardial infarct. Older adult abuse can also cause depression
Barthel Index of Activities of Daily Living	Evaluates if disability is present, estimates its extent, determines when support needed	Can ask information of patient or relatives; can assess improvement over time	Assesses adequate functioning in mobility and daily self-care tasks
Palliative Performance Scale	Progression of disease, symptom management, prognosis, and timing of hospice referral	Scores are given in 10-point increments, ranging from 0 (death) to 100 (full or normal, no disease)	Response to palliative care services. Five categories of function are scored; lower scores indicate greater functional impairment
Get-Up-and-Go Test	Combination of gait and balance to produce mobility	Patient stands up from seated position in chair, walks short distance, turns around, returns to sitting in chair; can be timed or not	Patient's performance is scored on 5-point scale; higher score indicates greater gait and balance problems as well as an increased risk of falling
Kayser-Jones Brief Oral Health Status Examination (BOHSE)	Rates condition of patient's oral health from 0 (normal) to 2 (problematic)	Ten-item exam identifies oral health problems, using a pen light, tongue depressor, and gauze	Assesses need for referral
Clock Drawing Test (CDT)	Assessment of cognitive decline. If found, medications and management techniques can be used	Patient is asked to draw clock face with a specific time. Score for drawing closed circle, 12 correct numbers in correct positions, with hands pointed accurately	Often given with MMSE. The CDT detects impairments in executive function, while MMSE assesses orientation, memory, and language functions. Useful for detecting dementia in early stages
Zarit Burden Interview	Patient's care needs effect on daily life of caregiver	22 items that describe personal strain and role strain on 5-point scale	Used by aging agencies to rate caregiver stress
Braden Scale	Determines an individual's risk for developing pressure ulcers	Level of severity of six indicators: sensory perception, moisture, activity, mobility, nutrition, and friction or shear	Commonly used with older adults who have medical or cognitive impairments, on admission and on regular basis
Berg Balance Test or Single Leg Stance Test	To check for risk of falls; to monitor progress in physical therapy treatment	Choice of 14 tasks range from standing up from a sitting position, to standing on one foot	Clinical balance assessment; rated effective by 70% of physiotherapists
Fullmer SPICES	Conditions that warrant further assessment for fall risk	Checks for six conditions: Sleep disorders, Problems with eating and feeding, Incontinence, Confusion, Evidence of falls, and Skin breakdown	Used on admission to prompt fall risk precautions if needed
Mini-Nutritional Assessment (MNA)	Malnutrition and risk of developing malnutrition	Six questions on food intake, weight loss, mobility, psychologic stress or acute disease, presence of dementia or depression, and BMI	Suggested use: quarterly for institutionalized older adults and yearly for normally nourished community-dwelling older adults

obtaining the patient's past health history and history of the present illness.

Evaluation of the Assessment Environment

Before the assessment visit, clear instructions should be provided to the patient and family about parking arrangements and the registration process. To make the older patient and family comfortable, environmental modifications should be made, if possible. Environmental modifications may include adequate lighting, decreased background noise, comfortable seating for the older patient and family, easily accessible restrooms, examination tables that can be raised or lowered to assist patients with disabilities, and availability of water or juice for patient use. Patient comfort will ease communication and improve the data collection process.

Accuracy of the Health History

The more information that the patient and family can organize ahead of time, the more accurate and efficient the assessment will be. Many clinics mail an information packet in advance of the visit so that the older patient can come prepared. This packet might include the following:

1. A past medical history form. This form can be completed at home and is helpful for patients with complicated medical histories. The dates of hospitalizations, operations, serious injuries or accidents, procedures, and illnesses can be ascertained beforehand to save time during the assessment appointment. The form would also include any history of adverse drug effects or allergies.
2. Instructions to bring in all prescription and over-the-counter medications and herbal products/vitamins/mineral supplements for review by the nurse.
3. Instructions to bring any medical records, laboratory or x-ray reports, electrocardiograms, reports of vaccination, and other pertinent health records that the patient or family may possess.
4. Instructions to write down and bring the names of all healthcare providers involved with the patient's healthcare, including primary care providers, specialists, and alternative medicine practitioners (e.g., acupuncturists, massage therapists, chiropractors).
5. Instructions to bring hearing aids, eyeglasses, and any assistive devices (canes, walkers, and so on).

Patience is a virtue when obtaining a history from an older adult, because often the individual's thought and verbal processes are slower than those of younger patients. The patient should be allowed adequate time to answer questions and report information (Kane et al., 2018).

SAFETY ALERT When an older patient who has been asked to bring all medications to a geriatric evaluation session arrives carrying a large bag of medication bottles, the nurse knows that the first notation on the problem list is likely to be "at risk for adverse drug reaction related to polypharmacy."

The history should include emphasis on the following:

- Review of acute and chronic medical problems
- Medications

- Disease prevention and health maintenance review: vaccinations, PPD (tuberculosis), cancer screenings. (Table 7-5: Health Screenings and Immunization Guidelines Across the Lifespan in the module on Health, Wellness, Illness and Injury provides a detailed listing of interventions recommended for older adults.)
- Functional status (activities of daily living)
- Social supports (family, spiritual affiliations, caregiver stress, safety of living environment)
- Finances
- Driving status and safety record
- Review of symptoms (patient/family perception of memory, dentition, taste, smell, nutrition, hearing, vision, falls, fractures, bowel and bladder function).

Often, a standardized form is used to guide and direct the process of obtaining a health history. The nurse should be aware of potential difficulties in obtaining health histories from older patients, including the following:

- **Communication difficulties.** Decreased hearing or vision and decreased mental processing and response times have an effect on accurate and successful communication.
- **Underreporting of symptoms.** Fear of being labeled as a complainer, fear of institutionalization, and fear of serious illness and death can influence symptom reporting.
- **Vague or nonspecific complaints.** These may be associated with cognitive impairment, drug or alcohol use or abuse, or atypical presentation of disease.
- **Multiple complaints.** Associated "masked" depression, presence of multiple chronic illnesses, and social isolation are often an older adult's cry for help.
- **Lack of time.** New patients scheduled for a geriatric assessment should have at least a 1-hour appointment with the gerontologic nurse. Shorter appointments will result in a hurried interview with missed information (Kane et al., 2018).

Social History

Holistic evaluation is not complete without an assessment of the patient's social support system. Many frail older adults receive support and supervision from family members and significant others to compensate for functional disabilities.

Key elements of the social history include the following:

- Past occupation and retirement status
- Family history (helpful when constructing a family genogram)
- Present and former marital status, including quality of the relationship(s)
- Identification of family members, with designation of level of involvement and place of residence
- Current living arrangements
- Family dynamics
- Family and caregiver expectations
- Economic status, including adequacy of health insurance
- Social activities and hobbies

- Mode of transportation
- Community involvement and support
- Religious involvement and spirituality.

Older individuals who exhibit symptoms of sadness or social isolation, who question their existence, who feel they are being punished by God, or who ask about availability of religious or spiritual counseling should be asked if they would like help with their spiritual concerns. Religion and spirituality can be a great source of hope and strength in times of need and crisis. Many healthcare facilities and community agencies have access to religious and spiritual counselors. They can connect older patients and their families with such assistance, especially in the absence of an ongoing relationship with a priest, minister, rabbi, or spiritual counselor.

If an assessment team includes a social worker, the nurse may collaborate with him or her closely to identify and address social problems. Older patients with inadequate health insurance can often be helped by accessing community services, free hospital services, hardship funds established for indigent patients by major drug companies, and referrals to community-based free clinics. This information is helpful to the nurse working with older patients in many settings. It is crucial for patients admitted to long-term care facilities, those expressing feelings of severe loneliness, or those who do not have a close relationship with another individual.

Functional Evaluation

A key part of the evaluation of the older adult patient is the assessment or systematic evaluation of the patient's level of function and self-care. Ongoing research supports the need for regular assessment of the older adult's risk for falls regardless of setting. By properly evaluating older adults and targeting risk factors for falls and functional decline, the nurse can promote greater independence and safety in older patients. Areas to target include self-care abilities, cognition, nutrition and feeding, continence, mobility, sleep, and skin care. A home visit or comprehensive questions about the patient's home environment can provide useful information about fall risks, other safety issues, and the patient's ability to function in that environment (see Skills 15.2 and 15.5 in Volume 3).

Lifestyle and Health Considerations

Well-adjusted older adults maintain an active lifestyle and involvement with others and often do not appear their age (**Figure 34-11** >>). Lifestyle changes occur in response to declining physical abilities and retirement. Participation in activities that promote the older adult's sense of self-worth and usefulness also provides opportunities for developing new friendships with others of similar abilities and interests. Intellectual function is maintained through continued intellectual pursuits. Content with their life review, well-adjusted older adults often enjoy their retirement years and accept death as the inevitable end of a productive life. The older adult who has not successfully resolved developmental crises may feel that life has been unfair. Despair and hopelessness may be evident in the individual's lack of activity and bitter complaining.

Source: Tom Wang/Shutterstock.

Figure 34-11 >> Well-adjusted older adults often enjoy their retirement.

Minimum Data Set

Assessment of an older patient for appropriate placement in a nursing home or within a long-term care system is done using the Minimum Data Set (MDS). The MDS is a comprehensive standardized multidisciplinary assessment used throughout the United States. The Omnibus Budget Reconciliation Act of 1987 (OBRA 87) mandated assessment of all residents of facilities funded by Medicare or Medicaid using the MDS. It is also completed on all residents admitted to Veterans Administration Community Living Centers (Saliba et al., 2012). The MDS is used for validating the need for long-term care, reimbursement, ongoing assessment of clinical problems, and assessment of and need to alter the current plan of care.

The MDS consists of a core set of screening, clinical, and functional measures:

- **Resident Assessment Protocols (RAPs)** are structured, problem-oriented guidelines that identify unique and relevant information about an older patient. This information is needed for formulating an individualized nursing care plan.
- **Resident Utilization Guidelines (RUGs)** determine the reimbursement the skilled nursing facility will receive for providing care to the older patient. Factors considered include the need for supportive therapy (physical, occupational, and/or speech), self-care ability of the older patient, and the need for special treatments such as feeding tubes or skin care.
- **Resident Assessment Instrument (RAI)** identifies medical problems and describes each older patient's functional ability in a comprehensive and standardized format. This information helps to formulate the plan of care and to evaluate progress toward goals, indicating when changes in the care plan are needed.

Categories of data gathered for the MDS include the following:

- Patient demographics and background
- Cognitive function
- Communication and hearing

- Mood and behavior patterns
- Psychosocial well-being
- Physical function and ADLs
- Bowel and bladder continence
- Diagnosed diseases
- Health conditions (weight, falls, and so on)
- Oral nutritional status
- Oral and dental status
- Skin condition
- Activity pursuits
- Medications

- Need for special services
- Discharge potential.

Certain information gathered for the MDS, such as data indicating functional decline or a poorly managed chronic disease, may trigger the need for further assessment using the RAPs. For instance, if information gathered for the MDS indicates that the nursing home resident has fallen, a RAP is triggered and indicates the need for direct gait assessment, medication review, and physical/occupational therapy evaluation.

Table 7–5, Recommended Health Promotion Activities for Adults, in the module on Health, Wellness, Illness, and Injury provides a detailed listing of interventions recommended for older adults.

REVIEW The Concept of Assessment

RELATE Link the Concepts

Linking the concept of assessment with the concept of caring interventions:

1. You are assigned to care for a patient who has been receiving tube feedings via a nasogastric tube that has been in place for several days. Prior to administering the first tube feeding of the shift, what assessments would you perform?
2. Would the assessment performed be an initial assessment or a problem-focused assessment? Explain your answer.

Linking the concept of assessment with the concept of clinical decision making:

3. You are assigned care of a 46-year-old man admitted for status asthmaticus. His condition has stabilized and discharge is planned for tomorrow. When you enter his room for the first time, you find that he is short of breath and he requests that you hand him his inhaler, which the physician ordered to be kept at the bedside for self-administration as needed. What will you do first? Which important assessment is needed? How would you handle a possible change in already-set discharge plans?
4. What critical thinking would you apply to the above situation?

Linking the concept of assessment with the concept of communication:

5. When collecting information for a health history, what strategies would you use when communicating with an older adult who has a hearing loss?
6. You are collecting information from the mother of a 3-year-old for a health history. The mother does not speak any English, but the 3-year-old does speak English. What communication strategies would you employ? What if the child was 9 years old and enrolled in third grade? Would those different characteristics cause you to change your communication strategy?

Linking the concept of assessment with the concept of legal issues:

7. You admit an adolescent to the adolescent unit of a local hospital and begin collecting data when you begin to suspect that the adolescent may be abusing substances. With an understanding of your legal obligation to the adolescent, as well as your knowledge that the parents want to help their child, how would you handle your suspicions if the parents are in the room with the child?

8. You are assessing an older adult and discover bruises that you suspect may be the result of abuse. The patient's son is in the room during the examination. What is the best legally appropriate action for you to take? What will you do if that initial approach does not clarify the situation?

READY Go to Volume 3: Clinical Nursing Skills

- Read Chapter 1 for general assessment skills, vital signs, and physical assessment.
- See Chapter 9 for skills related to assistive devices.
- See Chapter 10 for skills related to healthy eating habits.
- And see the skills in the Safety chapter for assessing for abuse, fall prevention, seizure precautions, environmental safety, fire safety, and preventing thermal and electrical injuries.

REFLECT Apply Your Knowledge

The nurse conducted a health history interview with Martha Washburn, a 67-year-old woman. The following are excerpts from the health history.

"Mrs. Washburn, I am going to ask you a lot of questions before your physical. I need to have correct responses, and I have to tell you, there will be a lot of them if we are to get to the root of your problem. I will use the information to develop a plan of care."

"What are you here for? Did someone come with you? I see on your chart that you have some problems with urination. Are you incontinent? How long have you had the problem?"

The nurse included the following questions: "What is your economic status? Do you go to church? What do you do when you are ill?"

"We need information about your family, so let's start with your parents. Are they alive? Do you have siblings?"

The nurse completed a review of symptoms and prepared the patient for the physical examination by showing her into a room and telling her to get undressed.

1. Critique the nurse's actions in the initial interview phase of the case study.
2. Identify the types of information the nurse was seeking in asking those questions.
3. Create alternative approaches and questioning techniques for the interview in the case study.
4. Describe your preparation for an interview of Mrs. Washburn.

Module 35

Caring Interventions

Module Outline and Learning Outcomes

The Concept of Caring Interventions

Nursing Theories of Caring

35.1 Outline nursing theories that bridge the gap between theory and practice.

Concepts Related to Caring Interventions

35.2 Outline the relationship between caring interventions and other concepts.

Knowledge and Caring

35.3 Differentiate the four types of knowledge used in nursing.

Caring Encounters and Holistic Nursing

35.4 Analyze holistic nursing as it relates to caring interventions.

Lifespan Considerations

35.5 Differentiate caring interventions appropriate for patients at different stages throughout the lifespan.

Caring for the Caregiver: Self-Care in Nursing

35.6 Analyze the importance of nurses caring for themselves.

>> The Concept of Caring Interventions

Concept Key Terms

Aesthetic knowing, 2464	Caring practice, 2461	Competence, 2467	Empowerment, 2467	Personal knowing, 2464
Caring, 2461	Compassion, 2467	Empirical knowing, 2464	Ethical knowing, 2465	Presencing, 2466

Caring is generally defined as ability “to feel interest or concern” (Merriam-Webster Online Dictionary, 2016), but in the context of the nursing profession, caring goes well beyond this simple explanation. Caring has been described as encompassing various intentions and actions. Brunton and Beaman (2000) identified the following caring behaviors: “In rank order [they] were appreciating the patient as a human being, showing respect for the patient, being sensitive to the patient, talking with the patient, treating patient information confidentially, treating the patient as an individual, encouraging the patient to call with problems, being honest with the patient, and listening attentively to the patient” (p. 451).

Caring is a concept that forms an integral part of nursing theory. That said, the concept of caring is not limited to the realm of academia. Research based on in-depth interviews of practicing nurses revealed that engaging in **caring practice** is an essential element in providing quality nursing care (Burhans & Alligood, 2010). One nurse participant who was chosen as representative of the initial sample described her experience of quality nursing: “If you have a person that’s actually caring and compassionate and concerned about the welfare of that individual, it’ll take you farther than if you are an expert clinician” (p. 1694).

To take it one step further, a currently accepted position within the field describes “nursing as situated caring” (Jarrin, 2012, p. 4); in other words, caring can only be understood in the context of the environment. Not only are physical time, space, and location relevant, but the nurse’s level of development, the situation’s specific circumstances, and both the nurse’s and patient’s value systems surrounding illness and healing are also central in affecting how caring is manifested. Depending on the perspective, nursing can be viewed as “technical actions and physical behavior . . . [or] caring thought, feeling, and intention behind the action” (p. 4), with the ideal being an amalgamation of the two. Although both elements form the foundation of nursing, “without caring our work would merely be tasks that could be performed by machines” (pp. 4–5).

Milton Mayeroff, author of the classic 1971 book *On Caring*, argued that at the heart of caring is “helping the other grow” (Mayeroff, 1990, p. 2). Mayeroff maintained that caring facilitates growth both in the person who exhibits caring and in the recipient, be it a person or thing, such as a concept, cause, or community. Under his framework, caring is not a finite action but rather a process that encourages self-actualization in the caregiver as well as development of the person receiving

care. Central to Mayeroff's concept of caring is that the caregiver must respect the individuality and separateness of the other by not inflicting a specific direction in the growth of the other.

Nursing Theories of Caring

The various nursing caring theories grew out of humanism, which the American Humanist Association (2016) defines as "a progressive philosophy of life that, without theism and other supernatural beliefs, affirms our ability and responsibility to lead ethical lives of personal fulfillment that aspire to the greater good of humanity." Although each caring theory underscores different aspects and perspectives, all agree that caring is "the essence of nursing and a central and unifying feature" (Blais, 2015).

Bridging the gap between theory and practice has been an ongoing issue in nursing. Research has revealed that patients are clear on what constitutes a good nurse: Caring behaviors such as honesty, sincerity, the willingness to listen to others, and the perspective that the patient is a person and not just an illness are of central importance to patient satisfaction (Van der Elst et al., 2012). The question then is how to take the various theoretical perspectives on caring and translate them into practice (Swanson, 2012).

Tonges and Ray (2011) described how University of North Carolina Hospitals (UNCH) developed a successful nursing care delivery model known as the Professional Practice Model (PPM). The PPM is "one approach to actualizing caring theory across a healthcare organization by systematically incorporating interventions that link nursing actions, caring processes, and expectations" (p. 374). The PPM "translated caring theory into specific caring behaviors and incorporated them in practice" (p. 375). One example was the implementation of a "no passing zone" in which a "No Passing" sign was posted in hallways as a reminder that if a patient's call light was flashing, any nurse passing by the light was obligated to check in with the patient, even if that nurse was not assigned to that specific patient. "This practice is designed to convey the availability of the entire staff to *do for* all patients on the unit" (p. 377). Providing high-quality care and a climate accepting of innovations in caring depends on the development of concrete strategies that allow nurses to link theoretical concepts to their on-the-job duties (Tonges et al., 2015).

Although caring theories have been designed with the nurse-patient relationship in mind, the basic tenets of caring can and also should be applied to the nurse-nurse relationship. Intense levels of stress caused by staff shortages and high-needs patients underscore the importance of nurses supporting each other. When nurses are supportive of each other, they not only are able to solve problems that arise from challenging situations, but they also "are inspired to care by being cared for themselves" (Longo, 2011, p. 8). Inappropriate behaviors, such as bullying, are being scrutinized in healthcare because of the potential negative impact on patient care and safety and worker well-being and satisfaction. These behaviors will not be supported in environments with empowering initiatives that recognize the skills and knowledge that nurses contribute to patient care (Longo, 2013).

Leininger's Theory of Culture Care Diversity and Universality

In the mid-1980s, Madeleine Leininger revolutionized nursing and transformed the concept of caring with the development of a new discipline called transcultural nursing, currently referred to as the theory of Culture Care Diversity and Universality (George, 2011). In an early publication she said that "nurses often labeled, avoided or talked down to the cultural strangers when they did not understand their behavior and needs" (Leininger, 1989, p. 7). Her study of anthropology provided much insight as to how culture played a crucial role in providing nursing care in order to maintain or encourage health.

In order for nurses to provide the highest quality of care to culturally diverse patients, Leininger presents three modes of action:

- Culture care preservation and/or maintenance involves caregivers performing actions and making choices that help patients retain their specific cultural values and beliefs.
- Culture care accommodation and/or negotiation refer to caregivers' efforts to assist patients in adapting to or working with others to achieve the best possible care.
- Culture care repatterning and/or restructuring describes caregiver interventions that support patients in evaluating and changing their approaches to promote improved health outcomes (Leininger & McFarland, 2006).

Roach's Theory of Caring as the Human Mode of Being

Sister M. Simone Roach's philosophical theory declares caring to be a core element of how humans operate, as well as an expression of interconnectedness: "Caring, as the human mode of being, is caring from the heart; caring from the core of one's being; caring as a response to one's experience of connectedness" (Roach, 1997, p. 16).

Although Roach's theory views humans as caring entities, it also maintains that caring within the context of nursing is distinct in that the specific traits of nurses are all grounded in caring. She has labeled these attributes the six Cs of caring: compassion, competence, confidence, conscience, commitment, and comportment. Refer to **Box 35-1** » for further explanation of each trait.

Boykin and Schoenhofer's Nursing as Caring Theory

In 1993, Anne Boykin and Savina O. Schoenhofer proposed their nursing theory of caring, which maintains that caring is a crucial element of being human, as well as an ongoing process rather than a goal to be achieved (George, 2011). They argue that nurses must be willing to accept that caring is never static; it continually changes and evolves throughout the span of their lives. At the heart of it all, nursing is caring. Boykin and Schoenhofer (2001) state that "being caring, that is, living one's commitment to this value 'important-in-itself' (Roach, 1984), fuels the nurse's growing in caring and enables the nurse in turn to nurture others in their living and growing in caring" (p. 19). Self-awareness is also essential to being a

Box 35–1**The Six Cs of Caring in Nursing**

Compassion. Awareness of one's relationship to others, sharing their joys, sorrows, pain, and accomplishments. Participation in the experience of another.

Competence. Having the knowledge, judgment, skills, energy, experience, and motivation to respond adequately to others within the demands of professional responsibilities.

Confidence. The quality that fosters trusting relationships. Comfort with self, patient, and family.

Conscience. Morals, ethics, and an informed sense of right and wrong. Awareness of personal responsibility.

Commitment. Convergence between one's desires and obligations and the deliberate choice to act in accordance with them.

Comportment. Appropriate demeanor, dress, and language that are in harmony with a caring presence. Presenting oneself as someone who respects others and in turn demands respect.

Source: Adapted from Roach, M. S. (2002). *Caring, the human mode of being: A blueprint for the health professions* (2nd ed.). Ottawa, ON: CHA Press. Reprinted with permission.

caring and effective nurse. Patients respond positively to their caregiver's authenticity, which encourages their own growth.

Watson's Theory of Human Care

Jean Watson's theory of human care has evolved as a result of her intense interest, varied education, and extensive experience with nursing, philosophy, and metaphysics (Watson, 1999). At the crux of her theory is the assumption that genuine caring relationships have a positive impact on a patient's health and can facilitate the healing process, putting caring at the core of nursing. Equally important is the preservation of the patient's dignity and a respect for all people's inevitable interconnectedness (George, 2011).

Also key to Watson's theory of human care is that caring is considered transpersonal; in other words, both the nurse and the patient seek out meaning and a sense of connectedness. Furthermore, Watson (1999) maintained that caring involves addressing not just the mind and the body, but also the spirit: "The value of human care and caring involves a higher sense of spirit of self. Caring calls for a philosophy of moral commitment toward protecting human dignity and preserving humanity" (p. 31).

When Watson first developed her theory, she identified what she referred to as the 10 carative factors that needed to exist within a nurse–patient caring relationship. She later updated those characteristics and renamed them the 10 clinical caritas processes. These include the process of practicing loving kindness and equanimity within the context of providing care; being authentically present with the patient; being present to and supportive of patients' expression of feelings—both positive and negative; and creating a healing environment at all levels (George, 2011).

Benner and Wrubel's Theory of Caring

Patricia Benner and Judith Wrubel's contribution to caring theories is grounded in their book *The Primacy of Caring: Stress and Coping in Health and Illness* (1989), which places

caring at the heart of providing quality service to patients and their families. In 2001, they further clarified their perspective as not focusing on nurse caregiving as much as on how care informs stress and coping responses: "Our main goal is to examine the phenomenon of care and caring practices to the experience of health and illness, not the caregiving of nurses" (p. 172). They describe a nurse's intent to care as only one factor in how caring is delivered and received. In other words, caring does not happen in a vacuum; it is dependent on other factors, such as the context of the situation, the physical environment, the nurse's training and experience, and the patient's unique capacities and perspectives (see Focus on Diversity and Culture) (Benner & Wrubel, 2001).

Focus on Diversity and Culture
Cultural Competence in Nursing

Cultural competence not only is imperative for nurses at the bedside but also relates to being a member of an influential global nursing community. There are many excellent cultural guides available detailing the healthcare concerns of various ethnicities; each new nurse should own one and refer to it frequently. Often, an overview to cultural care on ethnic groups commonly served by a hospital is provided in new graduate orientation. Below are some common areas of concern when providing care to someone from a different culture (Spector, 2017; Andrews & Boyle, 2016).

- Culture and religion can have an influence on how patients express pain and the meaning they attach to it. For instance, some cultures view pain as penance for a past wrongdoing or as a test of faith. Others see acknowledgment of pain and/or requests for pain relief as a sign of weakness.
- Certain cultures observe specific practices or rituals related to death and dying and may resist exploring the best options for end-of-life care.
- Families in some cultures approach healthcare decisions as a team as opposed to leaving the final decision of treatment to the individual in question.
- All distinctive practices of a specific culture or religion are not homogeneous within the same group, making it crucial that nurses be sensitive to such issues but also not make sweeping generalizations about an entire group of people. For example, younger members of a family may be less strict in their adherence to some cultural or religious practices than their grandparents or parents.

The Transcultural Nursing Society (Douglas et al., 2011), along with the Expert Panel for Global Nursing and Health of the American Academy of Nursing, has developed the Standards for Practice for culturally competent nursing care. These standards are broad-reaching, encompassing individual nursing care as well as actions by healthcare systems and governments. They address such concerns as social justice; knowledge of cultures; culturally competent practice; cultural competence in healthcare systems and organizations; patient advocacy and empowerment; a multicultural workforce; cross-cultural communication and leadership; and evidence-based practice and research (Douglas et al., 2011).

» **Stay Current:** For additional information on nursing and other cultures, visit the website of the Transcultural Nursing Society at <http://www.tcns.org/>.

Concepts Related to Caring Interventions

The caring interventions are fundamental to the entire nursing process. Caring—both for self and for others—is the essence of nursing. Self-care includes recognizing and tending to the nurse’s own physiologic and psychosocial needs, as well as seeking out activities that promote professional development. For the nurse, the negative impact of alterations in physical and mental health can extend to patient care, in terms of both the decision-making process and the actual care the nurse provides.

The relationship between caring interventions and professionalism carries important implications for nurses. In work environments where nurse shortages and poor working conditions exist, nurses have reported that quality of care suffers (Kutney-Lee et al., 2013). Furthermore, “improved work environments and reduced ratios of patients to nurses were associated with increased care quality and patient satisfaction,” whereas patient satisfaction is much lower in institutions where many nurses feel burned out and dissatisfied with their work conditions (Aiken et al., 2012).

Caring is directly linked to ethics, because it “can be considered a commitment to attending to and becoming enthusiastically involved in the patient’s needs” (Lachman, 2012, p. 114). Caring nurses are more inclined to hold high ethical standards, which unfortunately can lead to internal conflict, also referred to as moral distress. Moral distress is a phenomenon that encompasses many issues, such as a nurse knowing the right action to take, but being constrained from taking it; when nurses perceive less time available to give to their patients; when a leadership style is in conflict with providing better patient care; and when only inadequate consultative services are available to patients (de Veer et al., 2013).

Cultural influences affect coping styles, which, in turn, affect both care and self-care practices. For example, most Western cultures are considered to be individualist, which includes placing a high value on facing personal challenges individually and autonomously. In the context of an individualist culture, members from other cultures may be less likely to seek social support when managing stressful situations (Goh et al., 2015). As a result, when faced with a stressor, seeking social support may be viewed as unfavorable or even as a sign of weakness.

Cultural influences also inform the grieving process. Western expectations of autonomy may lead some providers to discount the importance of the family unit during times of grief but may also lead some patients to hesitate to ask family members for help or support. Similarly, individuals from different cultures may observe different rituals during the end of life. Nurses and other healthcare providers assess and facilitate the needs of all patients to observe cultural or traditional practices. Some, but not all, of the concepts integral to caring are shown in the Concepts Related to Caring Interventions feature. They are presented in alphabetical order.

Knowledge and Caring

In the context of nursing, researcher Barbara Carper (1978) outlined four types of knowledge, which she also refers to as knowledge patterns (p. 13): empirical, aesthetic, personal,

Figure 35-1 » The four ways of knowing.

and ethical (see **Figure 35-1** »). Important to note is that they do not exist independently, but rather they overlap and interact with each other. With a greater awareness of what knowledge encompasses, nurses are able to more efficiently draw on the full scope of their understanding so as to provide the highest quality care possible.

Empirical Knowing

The first type of knowledge Carper (1978) identified is empirical, which she also referred to “the science of nursing” (p. 14). **Empirical knowing** is twofold in that it is based in facts and observations relevant to nursing, as well as the analyses and theories that attempt to explain them. Nurses can develop this pattern of knowing through ongoing academic education and increasing their skills at operating from a place of objectivity when making observations.

Aesthetic Knowing

The next type of knowledge, **aesthetic knowing**, is also referred to as “the art of nursing” (Carper, 1978, p. 14). In contrast to the objective nature of empirical knowing, aesthetic knowing is subjective and relates to the specific personal style the nurse possesses when delivering care. Key elements of this pattern of knowing are empathy (p. 17), holistic thinking, compassion, and sensitivity (Berman, Snyder, & Frandsen, 2016). Development of this type of knowing involves the nurse’s commitment to increasing her awareness and respect regarding other people’s unique perspectives and experiences.

Personal Knowing

Carper (1978) identified **personal knowing** as another pattern of knowledge within nursing, referring to the nurse’s ongoing self-exploration and self-actualization. Developing this pattern of knowing involves “the nurse in the therapeutic use of

Concepts Related to Caring Interventions

CONCEPT	RELATIONSHIP TO CARING INTERVENTIONS	NURSING IMPLICATIONS
Culture and Diversity	Western cultural influences → autonomous coping highly valued → sense of weakness associated with seeking social support → tendency to avoid asking for help when needed → ineffective self-care	<ul style="list-style-type: none"> ■ Recognize cultural impact on beliefs about seeking help. ■ Assess personal beliefs regarding the value of social support. ■ Identify trusted sources of support and use resources as needed.
Ethics	Conflict between providing the best possible care for the patient could clash with the family's wishes or the constraining factors of the institution → leads nurse to experience moral distress → ↑ feelings of stress → ↑ risk for burnout	<ul style="list-style-type: none"> ■ Share ethical concerns with supervisor and healthcare team and build supportive networks on the job. ■ Attend workshops on moral distress to increase coping strategies. ■ Identify common causes of moral distress among nursing peers.
Grief and Loss	Western cultural influences assume personal autonomy and involvement in end-of-life decisions and care → disregard for non-Western patient/family preferences regarding end-of-life preferences → impaired patient/family/provider communication → increased grief and unhappiness by patient and family during stressful life event	<ul style="list-style-type: none"> ■ If patients/family from a non-Western culture reject such concepts as palliative care/hospice, advance directives, or organ donation, be respectful of these decisions. ■ Use chaplains and translators (if needed) to ensure that patient/family wishes regarding death and associated practices are fully understood by nurses and assistive personnel. ■ Accommodate patient/family wishes as much as possible to alleviate patient and family stress. ■ Demonstrate respect in all interactions with the patient/family.
Professionalism	Inadequate self-care → decreased level of physical and psychosocial wellness → decreased quality of work performance and weakened affiliation with profession of nursing → decreased level of demonstrated professionalism toward patients, peers, and other members of the healthcare team	<ul style="list-style-type: none"> ■ Assess self-wellness and recognize when limitations are being exceeded. ■ Be aware of warning signs that may signal burnout. ■ Recognize areas of self-care that are unhealthy and identify solutions that promote wellness.
Safety	Lack of knowledge regarding patient culture → incomplete nursing assessment and miscommunication → poor patient outcomes and dissatisfaction with healthcare providers and facility	<ul style="list-style-type: none"> ■ Use chaplains and translators (if needed) to ensure that information is accurately transmitted to patient and family. ■ Actively seek information about the patient's stated cultural and religious preferences. ■ Ensure that patient teaching is delivered using a culturally sensitive method that enhances understanding and supports decision making. ■ Safeguard against inserting racial or cultural stereotypes, biases, and prejudices that may affect patient care and safety.
Stress and Coping	Impaired coping → absence of self-care → stress, anxiety, or mild depression → errors in patient care	<ul style="list-style-type: none"> ■ Identify and acknowledge stressors. ■ Evaluate the efficacy of personal coping methods. ■ Develop healthy, effective coping methods.

self [which] rejects approaching the patient–client as an object and strives instead to actualize an authentic personal relationship between two persons” (p. 19). In order to do this, the nurse must be willing to critically reflect on his own thoughts, emotions, and actions in a professional context.

Ethical Knowing

The last form of knowledge pattern is **ethical knowing**, which Carper (1978) calls the “moral component” (p. 20). She clarified that this type of knowing is more extensive than the

ethical codes by which nurses are expected to abide; it also encompasses “all voluntary actions that are deliberate and subject to the judgment of right and wrong” (p. 20). Sometimes nurses grapple with situations in which values and beliefs prove to be incompatible. To develop this pattern of knowledge, nurses must be aware of and fully understand the current codes of ethics outlined for nurses, in addition to the values held by the institution in which they work. Furthermore, they should possess “an understanding of different philosophical positions regarding what is good, what ought

to be desired, what is right; of different ethical frameworks devised for dealing with the complexities of moral judgments; and of various orientations to the notion of obligation” (p. 20).

Clinical Example A

Mr. Bahdoon Osman, a 57-year-old man from Somalia, immigrated to Minnesota 5 years ago with his wife, son, and three daughters. Three days ago, he was rushed to the hospital for breathing and swallowing difficulties, the cause of which was a large tumor. Following emergent surgical resection of the tumor, Mr. Osman was diagnosed with stage IV esophageal cancer. The family is adamant that Mr. Osman not be informed of his terminal diagnosis, because Somali culture believes it is cruel to do so. The patient’s physician has presented his treatment options.

The charge nurse instructed Mr. Osman’s nurse, Joanne Williams, to speak only to the patient’s son about Mr. Osman’s care and not to his wife, explaining that according to Somali traditions, the father speaks for the family when outside the home. When the father is unable to do so, another adult man in the family, often the son, takes on the responsibility. The nurse finds this instruction challenging, especially seeing the obvious pain the patient’s wife is in watching her husband suffer. The son tells Joanne that it is important that they reposition Mr. Osman’s bed “so that it faces Mecca.” Because Joanne does not understand the son’s request, she asks Mr. Osman’s wife for further explanation. His wife avoids Joanne’s gaze and does not answer. The son firmly explains to Joanne that his mother does not have a say in the matter and repeats the request. Frustrated and upset at the lack of respect for Mr. Osman’s wife, Joanne curtly responds by saying it is impossible to move the bed and leaves the room.

Critical Thinking Questions

1. Did Joanne demonstrate caring? If so, how?
2. How could have Joanne dealt with the Osman family differently?
3. What strategies could Joanne have employed to address culturally specific healthcare issues for the family?

Caring Encounters and Holistic Nursing

The healthcare field is moving from its traditional focus on disease management to a more holistic patient-focused approach to care. The American Holistic Nurses Association (AHNA) (2016a) defines holistic nursing as “all nursing practice that has healing the whole person as its goal.” It is a philosophy and attitude that facilitates healing by recognizing the intertwined relationships among the “body, mind, emotion, spirit, social/cultural, relationship, context, and environment.” Nurses practicing the holistic approach seek to develop a bond with the patient to create a more personal and supportive environment. Complementing traditional treatments with alternative therapies, such as reiki, meditation, biofeedback, and journaling, is also an important part of holistic nursing (Dossey & Keegan, 2012). The goal is to go beyond addressing the illness in order to help patients achieve balance in their lives. In this respect, it places the nurse in the role of health educator and emphasizes the patient’s personal responsibility in maintaining health.

This approach to nursing has become more relevant in the face of the nation’s changing demographics. Increasingly, the general population is turning to complementary and integrative health practices, formerly known as “alternative” medicine, to address health issues. *Complementary* is a term that

Focus on Integrative Health How “Alternative” Is Complementary and Integrative Health in Nursing Today?

A growing number of adults and children in the United States have used healthcare approaches developed outside of Western, or conventional, medicine (NCCIH, 2016b). True alternative medicine is uncommon, because most people in the United States who use nonmainstream approaches use them along with conventional treatments (NCCIH, 2016b).

Integrative healthcare involves combining conventional and complementary approaches together in a coordinated way. NIH-affiliated researchers are currently exploring the potential benefits of integrative health in a variety of situations. Some of these include pain management for military personnel and veterans, using mindfulness meditation and self-hypnosis; relief of symptoms in cancer patients and survivors, using acupuncture and meditation; and programs to promote healthy behaviors using yoga and meditation- and mindfulness-based approaches (NCCIH, 2016b).

refers to a nonmainstream medical therapy or product used together with conventional medical practice, while the term *integrative* refers to a nonmainstream practice combined with conventional medicine. The latest figures from the National Health Interview Survey indicate that 32.2% of adults and almost 12% of children had made use of complementary health approaches in 2012 (National Center for Complementary and Integrative Health [NCCIH], 2016a). See the Focus on Integrative Health feature for more information.

Nurses must educate themselves on complementary health approaches and understand that not all alternative therapies work for all people, and some may even be harmful. Holistic understanding of the patient is required to advise patients on appropriate therapeutic interventions and treatments. Understanding the patient’s context is of great importance when deciding on care strategies. For example, recommending costly supplements that can only be found in a few select specialty shops for an older adult who lives alone with limited mobility and income would prove problematic.

Nursing Presence

Presencing is a nursing concept developed by Rosemarie Rizzo Parse that involves the interpersonal arts of perception and communication. Through presencing, the nurse immerses himself in an interaction with the patient that helps the patient define her health choices. It is the patient, then, who has the authority to make decisions about her health. The nurse acts as a guide through his presence, not in the sense that the nurse tends to the patient, but rather by being open, receptive, and available at all levels without judging or labeling. The nurse’s thinking flows with the patient’s, and the value systems of the patient direct outcomes, not those of the nurse. Parse described presencing as “face-to-face discussions, silent immersions, and lingering presence” (as cited in George, 2011, p. 493). In this sort of interaction, the nurse lets the other lead, which could involve dialoguing, simply being there (even if silently), and leaving a lasting memory of the interaction in the patient’s mind.

Another important nursing concept in this regard is *intentionality*, which refers to a nurse working in conjunction with those involved in the situation at hand as a cooperative force rather than attempting to impose her will. It is a philosophical mindset that surrenders the idea of directing outcomes and setting goals; instead, the nurse allows resistance to dissolve and a course of action to unfold (Watson, 2002). This perspective of “intentionality seeks to access the universal, life-spirit energy via manifesting one’s deep intentional focus on a specific mental object of attention and awareness . . . [thus inviting] spirit-energy to enter into one’s life and work, and into the caring-healing processes and outcomes” (p. 14).

Empowerment

Empowerment is a process whereby the patient develops the autonomy to identify her own health needs in lieu of being instructed how to do so (Berman et al., 2016). George (2011) said, “The basic element of empowerment is taking action to generate positive results at both the individual and the organizational level” (p. 199). Nurses, having established personal relationships of mutual respect, trust, and confidence with their patients, are in a unique position to empower them, thus increasing their independence. Nurses can facilitate empowerment by instructing patients on how they should perform certain functions, and in cases where a patient’s abilities are hindered, provide only the amount of assistance that is absolutely necessary. In addition, nurses can provide information and resources to patients and their families, explain what they can expect beyond their hospital stay, and give voice to their concerns and desires to administrators and others providing care.

Compassion

When describing the ideal nurse, **compassion** is a must, but debate exists within the nursing community about how to precisely define this quality. It is not uncommon for the terms *compassion* or *compassionate care* to be used interchangeably with other characteristics such as caring, sympathy, and empathy, highlighting the subjective nature of the concept (Bramley & Matiti, 2014). Compassion is not something a nurse can learn through academic study, but only through the willingness to become intimately involved with the patient’s experience. This often involves providing comfort to the patient—anything from validating the patient’s experience through attentive listening and eye contact to holding the patient’s hand in moments of pain, from adjusting the patient’s position in bed to gently providing a warm sponge bath (see **Figure 35-2** »). Another aspect of expressing compassion involves respecting the patient’s spiritual beliefs or lack thereof, regardless of the nurse’s personal opinions and values. Although nurses frequently cite time constraints as a barrier to compassion, research has shown that even brief interactions with patients can convey compassion, and that patients see compassion as closely aligned to the broader concept of conveying care within nursing practice (Bramley & Matiti, 2014).

Competence

Similar to Roach’s (2002) description of competence, Takase and Teraoka (2011) define **competence** “as the ability of a

Source: Juan Silva Productions/Getty Images.

Figure 35-2 » This nurse is using touch and presence to help comfort her patient.

nurse to effectively demonstrate a set of attributes, such as personal characteristics, professional attitude, values, knowledge, and skills, and to fulfill his/her professional responsibility through their practice. A competent person must possess these attributes, have the motivation and ability to use them, and must effectively use them to provide safe, effective, and professional nursing care to his/her patient” (p. 398). They outline specific attributes inherent in competence, including cognitive ability, participating in professional development, having an awareness of ethical and legal practices, guaranteeing quality and safety in care, and building relationships with patients and fellow nurses. Competence and compassion must coexist or patient care inevitably suffers. Competence without compassion can be, at best, off-putting and, at worst, impersonal and insensitive. Compassion in the absence of competence, however, presents real threats to patients’ safety and health.

The classic theory regarding the development of nursing competence is Benner’s (1982) novice-to-expert research on the lengthy process of nursing skills acquisition. Benner and Wrubel (1989) extended the thesis begun in the novice-to-expert work that caring is central to human expertise, to curing, and to healing. One of the unique goals of the latter publication was to distinguish the nursing perspective from purely psychologic, physiologic, or biomedical views (Benner & Wrubel, 1989).

Clinical Example B

Mrs. Julie Briggs is a 29-year-old woman who has undergone a left-breast lumpectomy, which also involved removing cancerous lymph nodes. As a result, she has been admitted to the hospital for a brief recovery period. The first postoperative day, Mrs. Briggs’s nurse, Tomas Crespo, overhears an argument between the patient and her father, who is pressuring his daughter to have a double mastectomy as a preventive course of treatment because the patient’s mother lost her life to breast cancer at age 36. Mrs. Briggs tells her father that she and her husband hope to conceive a child within the next year and she desperately wants to experience the bonding experience of breastfeeding. As he listens, Tomas is reminded of his wife’s difficulty in breastfeeding and thinks the patient shouldn’t place so much importance on it. After the patient’s father leaves, Tomas

enters the room and finds Mrs. Briggs crying. He pulls up a chair and asks her if she wants to talk. Mrs. Briggs says she's fine and collects herself. Tomas squeezes her hand and informs her that he is willing to listen, but she shakes her head no. While changing the patient's dressing, he allows a few minutes to pass before providing her with tips on how she can tend to her sutures when she is discharged in a couple of days, adding that he can also instruct her husband when he comes in later that evening. Upon completing Mrs. Briggs' care, Tomas tells her that there are support groups for young breast cancer survivors like her and promises to bring the information to her before the end of his shift.

Critical Thinking Questions

1. Did Tomas demonstrate presencing, empowerment, compassion, and competence in his interactions with Mrs. Briggs? If so, provide specific examples.
2. Could Tomas have approached the patient's dilemma differently? If so, how?

Lifespan Considerations

There are often some overarching themes that influence nurses as they provide caring interventions to patients of all ages. Obviously, one of the most important factors to consider, which is essential to all patient interactions and teaching, is the patient's developmental level. Developmental characteristics across the lifespan are discussed thoroughly in the module on Development. The presence of developmental delays and physical impairments will influence interactions with these patients and may require nurses to adjust delivery of their caring interventions to achieve optimal outcomes. Many areas can be impacted by developmental factors. Cultural and religious diversity, the presence of pain, the stress of a medical issue or emergency, the unfamiliar environment of the hospital or healthcare facility, and the context of the medical issue (e.g., accidents, chronic illnesses, the possibility of death, and associated psychologic issues such as grief and loss) all influence patient communication.

Furthermore, even though they may be performing caring interventions with only one patient, nurses often find that they are teaching and educating family members and caregivers at the same time. Thus, nurses find themselves accommodating a full range of developmental, psychologic, and sociocultural issues for several people when providing caring interventions. With the addition of family members and caregivers, caregiving becomes increasingly complicated and nuanced.

Caring Interventions for Infants

Nurses interacting with very young infants will likely find that as long as the environment is comfortable and a parent or caregiver present, infants will not object too much to being handled during caring interventions (see **Figure 35-3** »). Infants are fascinated by faces, and as they age they prefer faces that they know and recognize (Mash, Bornstein, & Arterberry, 2013). Babies are programmed to inherently provide important information—how they like to be treated, talked to, held, and comforted (American Academy of Pediatrics, 2016a). Aside from assessing developmental milestones and physical issues, nurses caring for infants must consider any pain or discomfort caused by interventions. Healthcare providers now know that infants experience

Source: Monkeybusinessimages/iStock/Getty Images.

Figure 35-3 » Having the parents nearby when providing care for infants is soothing.

pain, and interventions such as sucking (with or without sucrose) or pain medications, depending on the procedure, are necessary (Stevens et al., 2014). Often in these cases, nurses must act as an advocate for the infant to receive pain-relieving interventions during routine procedures such as heelsticks and circumcision (Carter, 2013).

Other areas being assessed with parents and caregivers include whether infants, especially preterm infants, are thriving and gaining weight (American Academy of Pediatrics, 2016a); whether parents in vulnerable or underserved populations who are enrolled in early intervention or parenting programs are adequately caring for the child (Benzies et al., 2013); whether bonding seems to be taking place between infant and caregiver (American Academy of Pediatrics, 2016b); and the emotional and mental health of the mother and/or caregiver (Leis et al., 2014), with especial attention given to detection of postpartum depression (O'Hara & McCabe, 2013).

During the toddler years, physical growth and motor development will slow, but toddlers experience tremendous intellectual, social, and emotional changes. At this stage, parents may become concerned regarding speech and language development, temperament and personality traits such as shyness or aggression, and social isolation that may indicate autism (American Academy of Pediatrics, 2016c; Autism Speaks, 2016). Caring interventions will be affected by the toddlers' self-directed behavior and innate suspicion of strangers. Parents and caregivers will be necessary in providing care during this time.

Caring Interventions for Children

Children during the preschool and school years still need a parent or caregiver present during procedures. If a child has been exposed to uncomfortable medical procedures, he or she may be leery of or cry during caring interventions. Children at this stage become capable of developing psychic pain that the nurse may have to address. Some of the global issues facing children at this stage are stress, anger, conflict, and bullying; natural and human-caused disasters, such as terrorism and school shootings; poverty and uncertain

housing; deployed parents and frequent moves (for children of military personnel); and emotional needs and emerging mental health problems (American Academy of Pediatrics, 2016d).

Caring Interventions for Adolescents

Adolescents may still need parents or caregivers present during times of medical challenge, such as surgery or an accident, but in general, they can handle medical procedures by themselves. They will also prefer privacy when interacting with healthcare providers. Nurses will find that adolescents will be more forthcoming with sensitive information regarding sexual practices and alcohol or drug use if questioned separately from their parents. Issues of concern with teens and parents include puberty; social development and relationships with peers, especially romantic attachments; gender identity; academic pressures; sexual, physical, and emotional abuse; and potential hazardous activities such as drunk driving and contact sports (American Academy of Pediatrics, 2016e). Parental relationship issues such as absent mothers or fathers, blended families with stepparents, or the presence of adopted/fostered children in the family may surge to the forefront during teen/family interactions with the provider (American Academy of Pediatrics, 2016f). The nurse may find that these issues, rather than a procedure or exam, become paramount during patient interactions.

Caring Interventions for Pregnant Women

Regardless of the caring intervention between the provider and pregnant woman, the nurse should keep in mind that he or she is always dealing with a dyad: the mother and the baby. Obviously, the expectant mother will assess every caring intervention in regard to its effect on the baby. Nurses must be sensitive to this concern and include this information in any patient teaching, especially regarding procedures, such as chorionic villus sampling to detect congenital abnormalities, that can present a genuine risk to the fetus (Mayo Clinic, 2016).

Nurses will also assess for signs of maternal alcohol or drug abuse and intimate partner violence (IPV). Pregnancy adds stress to interpersonal relationships and increases the incidence of IPV. The presence of partner alcohol misuse, jealousy, and suspicion of infidelity has been associated with psychologic and physical IPV victimization in the prenatal and postpartum periods (Hellmuth et al., 2013) and can lead to child abuse.

Research has indicated that the quality, rather than quantity, of prenatal care is more important to pregnant women (see **Figure 35-4** »). Under ideal situations, prenatal care represents an opportunity for health promotion and illness prevention, screening and assessment, information sharing, continuity of care, non-medicalization of pregnancy, and women-centeredness (Sword et al., 2012). Pregnant women, especially those from vulnerable populations, form opinions regarding the quality of care based on access, physical setting, and staff and care provider characteristics. However, they rank as most important interpersonal care processes such as respectful attitude, emotional support, approachable interaction style, and taking time (Sword et al., 2012). The

Figure 35-4 » Having a good rapport with patients is important for nurses in an obstetrics practice.

meaningful relationship characterized by trust that exists between a woman and her prenatal care provider has been a recurrent theme in research. Nurses must respect this relationship in all interactions.

Caring Interventions for Adults

Perhaps the biggest obstacle clinicians face with adults is actually getting them to access healthcare. Lack of time and financial resources are large issues, as well as lack of health insurance coverage and lack of specialty providers in rural and less populated areas.

Many young and middle-aged adults can operate computers, although the abundance of poor-quality health information can complicate nurse–patient interventions and interactions. Nurses are encouraged to become aware of reliable internet sites for healthcare information and steer patients to them (Johns Hopkins Medicine, 2016). Another care issue is adults' increased reliance on retail clinics (e.g., drugstore chain walk-in clinics) for both acute and primary care. Although research has found that retail clinics handle new, simple medical conditions adequately, subsequent follow-up care is not as comprehensive as it would be with a primary care provider (Reid et al., 2013).

Finally, many young adults do not connect with the healthcare system for primary care. A large care gap emerges as young adults transition from pediatric care, monitored by parents, into autonomous primary care. The primary concern is that many young adults neglect getting care for chronic childhood conditions such as asthma and diabetes (American College of Physicians, 2016). In all caring interventions and interactions with adults, nurses can emphasize the importance of having a medical home and routinely monitoring and treating chronic conditions.

Caring Interventions for Older Adults

The term *active aging* refers to the fact that many older adults are aging independently or with limited assistance from friends, work associates, neighbors, and family members. Many older adults do not have chronic illnesses or cognitive decline and primarily seek interaction with care

providers and other organizations to support quality of life. Healthy active older adults will seek complete and up-to-date information on caring interventions and will be engaged participants in their healthcare. Active older adults also seek opportunities to engage with others and live healthy, purposeful lives. Many may do so through interacting with organizations that work to improve the quality of life for older adults by creating vocational, social, and recreational opportunities. For example, many communities and organizations have developed extensive volunteer networks through collaborations among local Departments of Aging, Departments of Social Services, hospitals, and other organizations. These volunteer networks may recruit retired and active older adults to participate in meaningful volunteer opportunities in places such as hospitals, airports, libraries, and schools.

On the other hand, some older adults will develop physical and functional limitations and need to manage chronic medical conditions and comorbidities as they age. One of the largest issues elders face is securing care from providers, such as geriatricians, who can integrate all the findings from specialists into a comprehensive overview. There is a shortage of physicians and nurse providers of geriatric care in the United States because of factors such as limited payment, difficulty securing reimbursement from Medicare, and lower annual pay than other specialties (see **Figure 35-5** ») (AARP, 2016).

Nurses providing care to older adults should be mindful of negative attitudes that inhibit patient interactions: ageism, which is prejudice or discrimination based on age, and elderspeak, a type of simplified speech, characterized by shorter sentences and words, used when talking to older adults (Hanson, 2014). Research has shown that the primary factor causing negative nursing attitudes is lack of knowledge about gerontology and the aging process (Liu, Norman, & While, 2015). Other contributing factors are self-aging anxiety, commitment to nursing, and negative attitudes toward healthcare resources allocation among older people (Liu et al., 2015). Nurses can address these factors by continuing their education and by paying careful attention to patient–nurse interactions.

Caring for the Caregiver: Self-Care in Nursing

Self-care is of vital importance in nursing and should not be treated as peripheral to patient care. George (2011) describes self-care as the activities an individual performs independently to ensure personal well-being and good health. Examples of such activities include a balanced diet, regular exercise, adequate rest and sleep, recreational activities, and meditation and/or prayer.

Self-care is particularly relevant to the nursing profession because nurses tend to overlook their own well-being while focusing on the health of others. According to the National Institute for Occupational Safety and Health (2016), “cases of nonfatal occupational injury and illness among healthcare workers are among the highest of any industry sector” (para. 3). Complicating the issue, healthcare is the fastest-growing sector of the U.S. economy, employing over 18 million workers, with women representing nearly 80% of the healthcare work force (National Institute for Occupational Safety and Health, 2015). Healthcare workers face a wide range of hazards on the job, including exposure to emerging pathogens, needlestick injuries, back injuries, latex allergy, violence, and stress.

In addition, the pressures of work, family, school, and community commitments experienced by nurses often lead to exhaustion, burnout, and stress with potentially debilitating effects on the quality of care delivered to patients. One study looking at nurses in the United States and Europe found that a substantial proportion of nurses in every country reported quality-of-care deficits, high nurse burnout, job dissatisfaction, and intention to leave their current positions (Aiken et al., 2012). The study concluded that modification of organizational behaviors toward nurses, improvement of the hospital work environment, and better nurse staffing would help retain a qualified and committed nurse workforce, improve hospital care safety and quality, and result in improved patient outcomes (Aiken et al., 2012).

Self-care for nurses encompasses more than just being physically fit and healthy. The practices that lead to increased well-being also build self-esteem, which in turn helps individuals problem-solve critically and face challenges more efficiently. Taking a self-esteem questionnaire helps individuals increase self-awareness by putting them in touch with their feelings and emotions; only through self-awareness can an individual begin to change those aspects that lower self-esteem. There are a number of self-esteem instruments available for use on the internet and at college counseling services. Worthy of note is the connection between self-awareness and self-control. A lack of self-awareness can contribute to decreased emotional control (Faguy, 2012), which could be problematic for nurses and the patients receiving their care.

AHNA (2016b) has maintained that holistic nursing practice requires the integration of self-care and personal development activities into one’s life. Holistic nurses engage in self-assessment, self-care, and personal development, aware of being instruments of healing. Holistic nurses value themselves and mobilize the necessary resources to care for themselves, striving to achieve harmony and balance in their own lives and assisting others to do the same.

Evidence-Based Practice

Recognizing and Preventing Burnout in New Nurse Graduates

Problem

Nurses often function in high-pressure, short-staffed situations and are subject to rotating schedules and extended shifts. Despite the challenges associated with functioning in such an intense work environment, nurses tend to ignore feelings of fatigue, exhaustion, depression, and job dissatisfaction, believing that their colleagues must be feeling the same way. Consequently, many push self-care to the bottom of their list of priorities, ignoring even their most basic needs in order to meet job demands. This cycle leads to burnout.

The effects of nursing burnout take not only a personal emotional and physical toll, but they also adversely impact quality of care and patient satisfaction and lead to high turnover rates, contributing to the nursing shortage, which inevitably leads to even more burnout (Aiken et al., 2012; Chau et al., 2015). Much research has validated the relationship between poor patient outcomes, including 30-day inpatient mortality and failure-to-rescue rates, and factors such as nursing staffing levels, skill mix of baccalaureate-prepared registered nurses, and the overall nurse practice environment (Aiken et al., 2012; Chau et al., 2015).

Evidence

Most researchers have agreed that burnout consists of three components: emotional exhaustion, cynicism, and diminished personal efficacy, with emotional exhaustion and cynicism being considered the core elements of burnout (Spence Laschinger & Fida, 2014). Similar to other helping professions, the prevalence of burnout in nursing is particularly high because of the high emotional and physical demands of the work. Nursing burnout overall has been associated with heavy workloads, inadequate staffing levels, job dissatisfaction, absenteeism, turnover, depression, and career dissatisfaction (Ahola et al., 2014).

Alarming, new graduate nurses have the highest risk of experiencing burnout, with as many as 66% of new graduates experiencing severe burnout, primarily related to negative workplace conditions (Pineau Stam et al., 2015; Spence Laschinger & Fida, 2014). Moreover, approximately 17.5% of new nurses leave their first job within 1 year of starting their jobs (Kovner et al., 2014). Many factors causing burnout in recent graduates mirrored the concerns of experienced nurses. New-graduate burnout has been significantly related to lack of supervisor support, unmanageable workloads, absenteeism and turnover intentions, lower organizational commitment, and depression (Ahola et al., 2014).

A significant factor, usually considered to be part of the unfavorable working environment, is bullying or horizontal violence. Typically, nursing peers, physicians, or patient families were the main sources of bullying; some 29.5% of U.S. nurse graduates in one study had considered leaving the nursing profession because of bullying (Vogelpohl et al., 2013). Education of staff and authentic leadership committed to extinguishing horizontal violence are imperative for identifying and correcting negative behaviors in the workplace (Rush et al., 2014; Spence Laschinger, Wong, & Grau, 2012; Vogelpohl et al., 2013).

The personal and workplace resources can prevent new-graduate burnout. Research has shown that psychologic capital, structural empowerment, and perceived staffing adequacy were significant independent predictors of job satisfaction in recent graduates (Pineau Stam et al., 2015). Managers should ensure that empowerment structures are in place to support new graduate nurses' job satisfaction. Interventions that specifically support nurse graduates include orientation processes and ongoing management support that build psychologic capital in new graduate

nurses and create positive perceptions of the workplace, thus enhancing job satisfaction (Pineau Stam et al., 2015).

Some of the essential components of successful programs for transitioning nurse graduates into the workplace have been identified. Formal new graduate transition programs have resulted in good retention and improved competency. Evidence has suggested that new graduate education should focus on practical skill development; preceptors should receive a level of formal training; formal support, including respectful feedback to improve confidence and competence in practice, should be available at least through the difficult 6- to 9-month post-hire period; opportunities for connection with their peers should be provided; and organizations should strive to ensure that clinical units operate with healthy work environments (for example, by allocating patient responsibilities commensurate with the new nurse's beginning skill set) (Phillips, Esterman, & Kenny, 2015; Rush et al., 2013).

Implications

Because burnout is detrimental to both the nurse and the patient, it is crucial that nurses recognize the signs and symptoms of this phenomenon. The Maslach Burnout Inventory (Maslach & Jackson, 1981) is the most widely used tool for measuring burnout (Poghosyan, Aiken, & Sloane, 2009). This questionnaire, which is designed to identify burnout, groups symptoms into three categories:

- **Emotional exhaustion.** This is one of the earliest signs of burnout and can cause headaches, insomnia, indigestion, and weight fluctuations. It may manifest itself as feelings of dread about going to work. Examples include uncontrollable crying, queasiness, and/or headaches during the nurse's commute.
- **Personal accomplishment.** Overworked nurses tend to feel that patients, supervisors, and hospital administrators do not appreciate their efforts. This can lead to underperformance, which is an adaptive response to stress.
- **Depersonalization.** When a nurse no longer feels compassion for some of her patients, it could cause insensitive behavior when providing care.

New graduate nurses experiencing any of these symptoms should seek the advice of colleagues and supervisors on how to overcome burnout. Strategies include physical exercise, talking it through, reducing patient load, learning to say "no" to extra assignments and committee appointments, switching shifts, and even changing jobs. Burnout is a sign that something must change. Nurses who choose to ignore it will discover that the symptoms and negative consequences of those symptoms will only worsen.

Critical Thinking Application

1. How can a nurse differentiate between the typical stress experienced by all healthcare professionals and burnout?
2. A nurse is experiencing symptoms of burnout and has approached her supervisor for support and guidance. The supervisor tells her it is simply a part of working as a caregiver and to "push through it." What steps can this nurse take to cope and improve her situation?
3. A nurse observes one of his colleagues being brusque with patients (e.g., lack of eye contact, not providing direct answers, cutting off patients when speaking). When he questions his coworker, she says that she doesn't want to get too emotionally involved with her patients and is just maintaining a healthy distance between them. He knows that she is also going through a difficult divorce and custody battle. What should he do?

Maslow's Hierarchy of Needs

Psychologist Abraham Maslow (1943, 1968) identified five levels of needs, the lower of which must be fulfilled before an individual can move to the next level and eventually achieve self-actualization, the highest level. For an illustration of Maslow's human needs hierarchy and a discussion of his work and its implication for the nursing care of patients, refer to the module on Stress and Coping.

Physiologic Needs

Physiologic needs are also referred to as survival needs and include the necessities of food, water, air, sleep, and shelter. For example, the extended work hours and rotating shifts common to the nursing profession make it challenging to maintain a regular eating schedule and sleep routine and to participate in regular physical activity. A lack of physical activity has been associated with high rates of lower back pain and other physical ailments reported by healthcare professionals (Sung, 2013).

Physiologic needs can be satisfied in healthy and unhealthy ways. Nurses practice self-care when they make healthy choices regarding food (e.g., by choosing fruit as a snack between meals), drinks (i.e., by drinking water instead of soft drinks), and sleep. Managing a sleep schedule can be particularly challenging, especially for nurses whose families operate on different schedules than the nurse. Physical recreational activities also help nurses cope with limited sleep while enhancing their fitness level. For more information, see the exemplars on Physical Fitness and Exercise and Normal Sleep–Rest Patterns in the module on Health, Wellness, Illness, and Injury.

Safety

Needs at this level have both physical and psychologic aspects, which include bodily safety, financial security, and personal health. The American Nurses Association's (ANA) 2011 *Health and Safety Survey* (2013) reported that stress and overwork (74%) and musculoskeletal injury (62%) top the list of nurses' concerns; in addition, 34% of nurses reported concerns about physical assault by their patients, representing a 25% increase from the previous survey in 2001. Moreover, the ANA (2014) has recognized that nurse fatigue contributes to workplace errors and poor patient outcomes and has urged a stronger focus to prevent this problem. The ANA (2014) has endorsed some of the following recommendations:

- Involve nurses in the design of work schedules and use a regular and predictable schedule so nurses can plan for work and personal responsibilities.
- Limit work weeks to 40 hours within 7 days and work shifts to 12 hours.
- Eliminate the use of mandatory overtime as a "staffing solution."
- Promote frequent, uninterrupted rest breaks during work shifts.
- Enact official policy that confers RNs the right to accept or reject a work assignment based on preventing risks from fatigue. The policy should include conditions that a rejected assignment does not constitute patient abandonment, and that RNs should not experience adverse consequences in retaliation for such a decision.

Work–family conflict among nurses also has a negative effect on job satisfaction (Rantanen et al., 2013). When the

quality of a nurse's personal and family life suffers, so does job performance, which directly impacts patient satisfaction and service quality.

Belonging and Love

According to Maslow, when the lower physical needs are met, an individual is in a position to address higher psychologic needs. The sense of love and belonging that comes from relationships with family, friends, and colleagues is particularly important to nurses, who depend on solid support networks to help them talk through and cope with pressures of work. Venting is a healthy way to unload stress, but it is vital that nurses maintain patient confidentiality at all times, even when venting to other nurses.

Unfortunately, new nurses may find their desire and efforts to fit in at work thwarted by a culture of bullying that is prevalent in the nursing profession. "Nurses eat their young" (Townsend, 2012) is an old, familiar refrain, and there is evidence to support it: As mentioned in the Evidence-Based Practice feature in this module, newly graduated nurses have significantly higher resignation rates in their first year of practice (Gaffney et al., 2012). Victims of bullying experience distress, anxiety, feelings of isolation, and depression, and they subsequently show an increased use of sick time. New graduates are particularly vulnerable because they often lack confidence in their skills and thus crave acceptance and positive feedback from their peers. In addition to adversely affecting job performance and satisfaction, bullying leads to increased absenteeism and staff turnover, therefore risking patient safety by interfering with teamwork, collaboration, and communication.

Clinical Example C

Mrs. Oden, the charge nurse on a medical–surgical unit, assigns extra patients to Celia Hammond, a new graduate nurse, in order to cover for a colleague who left unexpectedly to tend to a family emergency. Mr. Stephen Suskind, a 57-year-old man recovering from knee surgery, is among Celia's patients. In the early afternoon, Mr. Suskind falls while attempting to make his way to the bathroom unassisted. The sound of the fall and his subsequent cry prompt Celia to rush into his room. As Celia helps Mr. Suskind to stand, Mrs. Oden appears in the doorway and criticizes Celia harshly for having neglected her patient, as well as for attempting to move him after his fall. The commotion attracts the attention of other nurses on the floor, who stand behind Mrs. Oden, observing Celia as she is being chastised. Afterward, Celia discusses the incident with an experienced colleague who has worked at the hospital for more than a decade. When Celia complains about having been publicly humiliated, her colleague advises her to "suck it up" and closes the conversation by warning her that "no one likes a whiner."

Critical Thinking Questions

1. What should Celia do next?
 2. How have Mrs. Oden, Celia's nurse colleague, and others reinforced a culture of bullying?
 3. What actions might the nursing supervisor take to address incidents such as this one?
-

Self-esteem

Needs at this particular level include feelings of confidence, independence, competence, respect, and achievement. In nursing, a caregiver's self-esteem is based on how he/she is viewed by others. Nurses strive to be seen as competent and proficient and value the respect of peers. It is important for

new nurses to realize that nursing proficiency comes through hands-on practice. Skills are improved and mastered over time; thus, new nurses should not compare themselves to more experienced colleagues by being overly self-critical. Instead, they should maintain a positive mindset and be open to learning. Knowledgeable, sympathetic preceptors can enhance the skills acquisition of new nurses during their orientation to a hospital or other healthcare facility.

A mentor can also play an important role in encouraging a new nurse's self-esteem needs by supporting the new nurse's skill development and sharing experiences. Many healthcare institutions have mentoring programs where new nurses are paired with established colleagues who serve to teach, counsel, aid, and encourage them. In cases where mentoring programs have not been institutionalized, new nurses can still reach out to experienced colleagues and build a mentoring relationship with someone whose style and behavior they admire (Sullivan, 2013).

Self-actualization

After meeting the lower-level needs, an individual can then strive to develop her maximum potential and fully realize her abilities and qualities. Part of self-actualization for nurses is the need to make time for themselves. This crucial aspect of self-care includes pursuing activities that bring joy and stimulate creativity. Artistic pursuits, such as writing, playing a musical instrument, and dancing, can serve as important outlets for self-expression. Hobbies are important to personal well-being, because they offer a healthy distraction from the pressures of work and encourage personal development. Taking a break to do nothing in particular is also an effective way to relax and reenergize.

Choosing Wellness

Wellness is a state of well-being involving sound nutrition, regular physical fitness, stable emotional health, self-responsibility, dynamic personal and professional growth, and preventive healthcare. Currently, nurses are promoting patient wellness through the *Healthy People 2020* program, which builds on efforts dating back to 1979 when the Surgeon General issued the original *Healthy People* report (Berman et al., 2016). (See the exemplars on Physical Fitness and Exercise and Normal Sleep-Rest Patterns in the module on Health, Wellness, and Illness for specifics.) Nurses would do well to adopt the same healthy principles in their own lives.

Avoiding Unhealthy Behaviors

In addition to adapting healthy behaviors, self-care is also about avoiding unhealthy ones. Smoking, abusing alcohol and drugs, and misusing medications are all destructive lifestyle choices that impact a nurse's personal and professional life.

An estimated 10–15% of all nurses may be impaired by or in recovery from some form of drug or alcohol addiction (Thomas & Siela, 2011). However, only a small percentage of the employed nursing population has been identified with substance use problems in the United States and its territories (Monroe et al., 2013). Approximately 71% of impaired nurses do enroll in substance abuse monitoring programs, which are viewed as less punitive than disciplinary programs run by state boards. The prevalence of nurses identified with a substance use problem requiring an intervention and treatment is lower than the prevalence of those receiving substance abuse

treatment in the general population (0.51% vs. 1.0%) (Monroe et al., 2013).

Another major concern is the alcohol- or substance-impaired student nurse who increases risks to consumers by unsafe practice. Nursing students are at risk for alcohol and substance use for various reasons: lack of addiction/alcohol education; stress/anxiety from nursing program expectations; unhealthy habits, social isolation, and individual influences; peer influence/the college experience; and ineffective and unenforced campus policies (Nair et al., 2016). There has been little recent research about the numbers of nursing students with alcohol- and substance-use issues, but statistics presumably are in line with those of the general college population regarding to frequency of use and substance preference. One identified issue has been inconsistency among national and state healthcare organizations, clinical agencies, and colleges and universities regarding educational/professional policies addressing impaired nursing students (McCulloh Nair et al., 2015).

Nurses with a substance abuse problem are in a unique position given their access to drugs in the workplace. Further, beyond the harm they do to themselves, substance-abusing nurses may also inadvertently harm patients in their care. Fellow nurses are usually required to report impaired colleagues to management, and it is therefore vital that they recognize the telltale signs of substance abuse. Nurses with a drug or alcohol problem may exhibit one or more of the manifestations described in the module on Addiction (e.g., mood swings, tremors, slurred speech, or unsteady gait), as well as any of the following: discrepancies in documentation of controlled substances; volunteering to medicate coworkers' patients; wearing long sleeves in hot weather; committing frequent errors in care, particularly medication errors; arriving to work early or staying late; and coming in when not scheduled to work.

Workplace risk factors for substance use among nurses include the following (Bettinardi-Angres, Pickett, & Patrick, 2012):

- Easy access, role strain, and enabling behaviors by peers
- Seeing drugs as an acceptable means of coping with life's problems
- Developing an overarching faith in the ability of drugs to promote healing
- Rationalizing drug use on the basis of needing to continue working
- Feeling invulnerable to illnesses
- Developing a permissive attitude toward self-diagnosing
- Self-treating physical pain or stress.

Fellow nurses can help by making abusers aware of the issue and encouraging them to seek assistance options, such as counseling and treatment programs. Before reporting a colleague to management, a nurse may wish to give the fellow nurse the opportunity to self-report. Administrators tend to look more favorably on nurses who admit to their substance abuse problems (Cadiz et al., 2015). Nurses should especially keep an eye out for colleagues who have experienced a recent stressful life event, such as an accident or a divorce, because these experiences tend to increase the likelihood of resorting to some form of substance abuse to cope with the situation (Thomas & Siela, 2011).

Addiction is considered to be an illness. Nurses experiencing substance abuse should be referred to treatment, not punished. The majority of states have alternative-to-discipline programs (ADPs) affiliated with or recognized by their state boards of nursing. Increasingly, professional associations such as state nurses' associations are providing resources to help nurses recover from alcohol and drug addiction.

» **Stay Current:** For more information about nurses and substance abuse, visit <https://www.ncsbn.org/substance-use-in-nursing.htm>.

Choosing Healthy Behaviors

A healthy lifestyle is particularly important to nurses for two main reasons: (1) They must maintain strong immune systems in order to work with people who are ill and (2) they should act as role models so as to maintain credibility when advising others about healthy choices. Balance and moderation are the keys to a healthy lifestyle, and this is especially true with respect to nutrition and exercise.

Because personal physical, mental, and emotional health is integral to successful nursing practice, the ANA has published a book on the subject, *Self-care and You: Caring for the Caregiver* (Richards, Sheen, & Mazzer, 2014). Suggestions include the following: Maintain a regular eating schedule; eat balanced, nutritious foods throughout the day; exercise at least three times a week (e.g., take a walk, work out, participate in sports); set aside time for rest and relaxation; seek the company of supportive people; do something enjoyable every day (e.g., play a musical instrument, cook, read, watch TV); avoid tobacco, alcohol, and drugs; maintain an optimistic attitude; set limits with others; and prioritize tasks (Richards et al., 2014).

Maintaining a regular eating schedule is a challenge in a profession where rotating shifts and unexpected events are the norm. Nonetheless, nurses need to make time to address their nutritional needs and not wait until the effects of hunger and thirst (pangs, dizziness, seeing spots, and so on) are felt. Nurses can accomplish this by planning ahead and making sure that healthy snacks and fresh water are on hand to consume at predetermined moments of the work shift. Nurses with physically demanding tasks often make the mistake of thinking they are getting enough physical exercise at work; however, standing for long periods of time, lifting patients, and performing other tasks that require physical exertion are not likely to build muscle tone or contribute to cardiovascular fitness (see **Figure 35-6**) (Richards et al., 2014).

Self-awareness is the key to effective self-care. It involves self-discovery and leads to personal insights. For instance, a self-aware individual is able to identify personal strengths and weaknesses and is conscious of the assumptions, beliefs, values, and prejudices that can impair judgment. Through self-awareness, a nurse gains greater understanding of others, as well as increased respect and empathy for them (Sergeant

Figure 35-6 » Many nursing tasks are physically demanding. Nurses should incorporate regular exercise into their schedules to build muscle tone and fitness.

& Laws-Chapman, 2012). Koren and Papamitriou (2013) suggested that nurses take time to reflect and think about questions such as why they chose to go into nursing and what motivates them to go in to work every day.

In addition, nurses should take advantage of the support services available to them. At some healthcare facilities, nurses come together for weekly support groups to discuss their cases, providing a venue for them to reflect on their work and receive the benefit of their peers' experiences. Hospital chaplains are also available to listen to and support nurses (Koren & Papamitriou, 2013). For problems such as addiction and depression or health promotion activities such as engaging in a wellness program, nurses may be able to turn to employee assistance programs that are part of their employee benefits (Claxton et al., 2013).

Several professional associations, such as AHNA and state nursing organizations, provide programs and additional resources to help nurses cope with the stressors and pressures of their everyday lives. Online services, such as community forums, offer nurses a safe space where they can vent freely to others who understand the issues they face. Nurses must remember to respect patient privacy and confidentiality during group discussions or in online forums.

REVIEW The Concept of Caring Interventions

RELATE Link the Concepts

Linking the concept of caring interventions with the concept of health, wellness, and illness:

1. Apply theories of caring to discuss how the benefits of self-care (improved physical fitness, overall health, self-esteem, and self-actualization) impact patient care.

2. Explain the relationship between self-care and wellness. Is the absence of illness a requirement for wellness? Why or why not?

Linking the concept of caring interventions with the concept of comfort:

3. In the psychosocial realm, how would an absence of genuine caring impact the nursing care for a patient who is receiving end-of-life care?

4. Describe the application of presencing when caring for the family members of a patient who is receiving end-of-life care.

Linking the concept of caring interventions with the concept of communication:

5. From the patient's perspective, how might inadequate self-care affect facets of the nurse's nonverbal communication, such as personal appearance and facial expression?
6. How does confidence, identified by Roach as a caring trait, impact the quality of communication between the nurse and the patient?

READY Go to Volume 3: Clinical Nursing Skills

All of *Volume 3: Clinical Nursing Skills* is devoted to individual caring interventions. The book is conveniently indexed to facilitate quick access to the step-by-step nursing skills. Often, nursing skills take place within the context of a nursing assessment, monitoring vital signs, or administering medications. Here are some links to performing these foundation skills:

- SKILL 1.1 Appearance and Mental Status: Assessing
- SKILL 1.5 Blood Pressure: Newborn, Infant, Child, Adult, Obtaining
- SKILL 1.9 Temperature, Newborn, Infant, Child, Adult, Obtaining
- SKILL 1.22 Neurologic Status: Assessing
- SKILL 2.11 Medications: Preparing and Administering

Finally, keep in mind that many hospitals and healthcare facilities maintain protocols and procedure guidelines for nurses and educational handouts for patients on the facility's intranet, or internal computer network. Nurses should be able to access these documents from computer workstations within the facility.

REFLECT Apply Your Knowledge

Ms. Ann Mah, a 26-year-old single woman, was admitted to the hospital following an automobile crash. She lost consciousness at the wheel while driving home from the gym by herself. Since her admission, she has been diagnosed with a neck injury, and a neurologic workup revealed she has epilepsy. Her nurse, Michael Robbins, is monitoring her blood pressure and assessing her for side effects related to her newly prescribed anticonvulsant medication, valproate (Depakote).

When Michael enters the room, he finds Ms. Mah gazing out the window. When he asks how she is doing, she responds with a curt "Fine." As he goes through his list of questions, she answers with just one or two words. He senses that she is a very private person, so he avoids asking her personal questions. Later in the day, he asks his mentor for advice on the case, who tells him to be patient and allow

the patient time to open up. His mentor also informs him that some patients diagnosed with chronic illness may experience the diagnosis as a loss of their ideal selves and have difficulty accepting the diagnosis at first.

After his next assessment, Michael decides to spend an extra 5 minutes with Ms. Mah. He sits by her bedside quietly, observing her out of the corner of his eye as he pretends to review her file. Suddenly, she blurts out:

"I hate this! My life was perfect. I was promoted to regional director of sales last week. I drove around all over the city and I had a great social life. Now you tell me I'm epileptic. What are they going to say at work?"

Michael responds, "I hear your concern that the diagnosis of epilepsy may interfere with your life and work. And you're right, epilepsy does require adjustments. But you are the same woman you were before the accident. Except that now you know that the woman who was promoted to regional sales director has epilepsy. Tell me what else you're concerned about."

Ms. Mah looks away. "With this stupid medicine, I can't keep any food down!"

"I know that's frustrating, but it is important that we try to prevent another seizure, especially because of your neck injury. The idea is to gradually reduce the dosage to lessen the side effects as much as possible while still controlling the seizures. Does that make sense?"

"Yes, but I really don't want to take medication the rest of my life, especially not this stuff."

Michael nods his head to show that he's listening and answers, "I understand that. Let's do this: I'll email the attending provider who is managing your care and ask her to come around and discuss the medication with you. Would that be all right?"

Ms. Mah turns her head to look at Michael. "Yes. Thank you."

Michael says, "I know you're concerned about work and returning to your social life. How about we come up with a plan for how you might begin to manage your epilepsy after you leave here?"

Ms. Mah replies, "I'd like that. I spoke with my sister yesterday. She told me there are other ways to treat epilepsy. She mentioned acupuncture."

"I've heard that, too. Let's look into it and talk about some more ideas the next time I see you. Deal?"

Michael stretches out his hand and after a few seconds Ms. Mah takes it and they shake on it.

At his next assessment, Michael finds Ms. Mah reading information from an epilepsy website off a tablet.

"How are you today, Ms. Mah?" Michael asks.

"Fine. Today, I'll be asking the questions," Ms. Mah says.

1. Which caring theories are relevant to this case?
2. Which holistic approaches did Michael employ?
3. How did Michael's self-care aid him in caring for Ms. Mah?

Module 36

Clinical Decision Making

Module Outline and Learning Outcomes

The Concept of Clinical Decision Making

Critical Thinking

36.1 Analyze the use of critical thinking skills in nursing.

Clinical Decision Making

36.2 Analyze the components of clinical decision making.

Clinical Judgment

36.3 Outline the components of clinical judgment.

Lifespan Considerations

36.4 Differentiate considerations related to clinical decision making about patients throughout the lifespan.

Concepts Related to Clinical Decision Making

36.5 Outline the relationship between clinical decision making and other concepts.

Clinical Decision Making Exemplars

Exemplar 36.A The Nursing Process

36.A Analyze the nursing process as it relates to clinical decision making.

Exemplar 36.B The Nursing Plan of Care

36.B Analyze nursing plans of care as they relate to clinical decision making.

Exemplar 36.C Prioritizing Care

36.C Analyze prioritizing care as it relates to clinical decision making.

>> The Concept of Clinical Decision Making

Inductive reasoning, **2483**

Inquiry, **2482**

Intellect, **2480**

Intuition, **2484**

Reflection, **2483**

Salient cue, **2481**

Clinical decision making is a process nurses use in the clinical setting to evaluate and select the best actions to meet desired goals. Nurses use clinical decision making whenever choices are available, even when they evaluate a situation and decide not to act. In some cases, decisions are required in situations that have neither clear answers nor standard procedures and when conflicting forces add to the complexity. At other times, decisions are routine. For example, a nurse is assigned five patients:

- A patient with a 1-day-old abdominal surgical site
- A patient who was admitted in sickle cell crisis
- A patient with an arm wound infected with MRSA who is in contact isolation
- A patient who has been crying all night
- A patient who is already up and walking down the hall of the unit.

Clinical decision making applies across the continuum of nursing care, from direct patient care at the bedside to professional behaviors and accountability inherent in the profession of nursing. The nurse must evaluate each patient's needs and preferences as well as time-constraining activities (e.g., medication administration) to make appropriate decisions for each patient (see Exemplar 36.C on Prioritizing Care for further information). To make these decisions, the nurse must use critical thinking to choose among alternatives that support the best patient outcomes for all five patients.

Critical Thinking

Patient outcomes improve when the nurse uses critical thinking. Failure to employ critical thinking results in wasted time and energy, poor-quality patient outcomes, frustration, and anxiety (Elder & Paul, 2013). The American

Association of Colleges of Nursing’s (2008) *The Essentials of Baccalaureate Education for Professional Nursing Practice* defines **critical thinking** as “All or part of the process of questioning, analysis, synthesis, interpretation, inference, inductive and deductive reasoning, intuition, application, and creativity.” The Accreditation Commission for Education in Nursing speaks of critical thinking as “the deliberate nonlinear process of collecting, interpreting, analyzing, drawing conclusions about, presenting, and evaluating information that is both factually and belief based” (Benner, Hughes, & Sutphen, 2008). These statements, and those by other professional nursing organizations, underscore the importance of today’s nurses being able to make meaningful observations, solve problems, and decide on a course of action. To do so, nurses must be able to process both previously learned and newly acquired information about their patients, the work environment, and resources at hand or in the community as well as applicable evidence related to care of the patient; the nurse must then be able to prioritize this information quickly and efficiently.

Nurses use critical thinking skills in a variety of ways. Because nurses manage patient care and human responses holistically, they must draw meaningful information from other disciplines in order to understand the meaning of patient data and plan effective interventions. This can be challenging because nurses work in rapidly changing situations. Routine actions are not always adequate to deal with the situation at hand. Familiarity with the routine for giving medications, for example, does not help the nurse in a situation with a patient who is frightened of injections or does not wish to take a medication. When unexpected situations arise, critical thinking enables the nurse to recognize the situation, respond quickly, and adapt interventions to meet specific patient needs. Nurses must use critical thinking, for example, to decide if observations should be reported to the primary care provider immediately or if those observations can wait to be reported after morning rounds. The skills and abilities necessary to develop critical thinking include intellect, creativity, inquiry, reasoning, reflection, and intuition (Figure 36–1 >>). Critical thinking also requires maintaining an attitude that promotes critical thinking and working in an environment that encourages this skill (Table 36–1 >>).

SAFETY ALERT A cross-sectional review of 2699 patient medical records from hospitals found that 76.8% of patient-related adverse events were attributable to nursing. Patients had an average of 15.3% risk of experiencing an adverse event. Of those patients who experienced adverse events attributed to nursing, 30% experienced at least two adverse events (D’Amour et al., 2014). In a time of economic restraint with healthcare reimbursement linked to patient satisfaction, adverse healthcare events are costly for institutions, pose a risk to patient safety, and diminish patient confidence in healthcare institutions and in nursing (D’Amour et al., 2014).

Intellect

Intellect is defined as the ability to think, understand, and reason. Building on clinical knowledge and skills expands the knowledge base nurses use for reasoning, analyzing, and predicting patient outcomes. Intellect helps to differentiate facts from opinions, approach situations objectively,

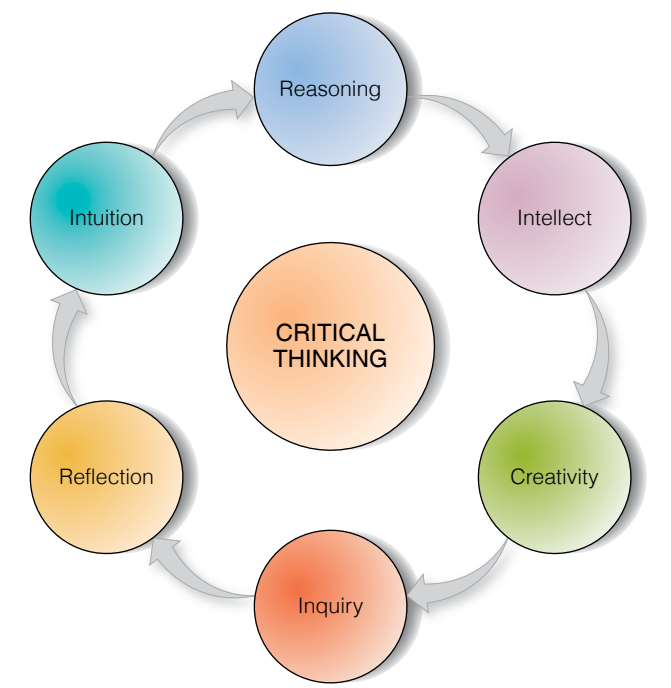

Figure 36–1 >> Critical thinking skills are essential for making clinical decisions.

TABLE 36–1 Common Attitudes of Critical Thinkers

Attitudes	Examples
Independence	<ul style="list-style-type: none"> Does own thinking, objectively and honestly. Is open minded about different methods used to reach same goal. Looks for the facts; not easily swayed by opinions.
Fair-mindedness	<ul style="list-style-type: none"> Has neutral judgments without bias. Considers opposing views to understand all aspects before making decisions. Is open to new ideas and ways of doing things.
Aware of self-limits	<ul style="list-style-type: none"> Knows limits of intellect and experience. Seeks new knowledge or skills in current evidence. Expresses a willingness to self-reflect on own beliefs and ideas.
Integrity	<ul style="list-style-type: none"> Challenges own ideas and methods of doing nursing care. Evaluates inconsistencies within own nursing practice. Chooses the right thing to do over the popular thing to do.
Perseverance	<ul style="list-style-type: none"> Has stick-with-it motivation to find the best solution for quality patient outcomes. Is patient with processes.
Confidence	<ul style="list-style-type: none"> Knows that he knows what he knows. Trusts the skills and abilities of intellect, creativity, inquiry, reasoning, reflection, and intuition.

and clarify concepts. Thinking becomes an intentional action to identify **salient cues** within a clinical situation. *Salient*, or significant, means the leading, most noticeable, or most important, and *cue* refers to significant data that informs and influences conclusions about the patient's health status. Salient cues can cluster to form a pattern that can be translated into a nursing diagnosis for the patient. A salient cue does one of the following:

- **Indicates a negative or positive change in a patient's health status or pattern.** For example, the patient states, "I have been experiencing shortness of breath when climbing stairs."
- **Varies from norms of the patient population.** The patient's pattern may vary from norms of the general society. For example, an adult patient may consider a pattern of eating two small meals a day to be normal.
- **Indicates a developmental delay.** The nurse must be aware of the normal patterns and changes that occur as the person grows and develops. For example, by age 9 months an infant is usually able to sit alone without support. The infant who has not accomplished this task requires further assessment for possible developmental delays.

Once salient cues are recognized, they can be clustered to determine whether any patterns are present. The nurse can then interpret the pattern and take appropriate action. Awareness of cues and their significance can be valuable in making clinical decisions essential to nursing care for ever-changing conditions and reordering of priorities to meet patient needs (Burbach & Thompson, 2014). This dynamic method of thinking evolves over time, very much in the way that nurses advance through the stages of skill acquisition as they gain experience in clinical care. New nurses need to write down the assessment data and search the data for abnormal cues to help cluster significant cues that can be translated into a nursing diagnosis. See **Figure 36-2** for an example of cues and clustering of data.

Continuous learning is necessary for nurses to remain current with the best evidence for quality patient outcomes (see the feature on Evidence-Based Practice for further information). Many states now require that for licensure renewal, nurses complete continuing education credits to demonstrate up-to-date and current knowledge in patient care.

Creativity

Creativity is an outlet for the imagination that allows a nurse to take what can be seen in the mind and make it tangible. **Creativity** means finding unique solutions to unique problems when traditional interventions are not effective; for example, finding just the right way to connect with a patient who does not want to talk about her diabetes or finding interventions that best help a patient meet a goal so he can be discharged from the hospital.

A modification to an old adage, "No one size fits all" describes the importance of individualizing nursing care for each patient. When an attempt to help a patient is not successful, the nurse changes tactics and asks the question,

Figure 36-2 Random cues are not similar to each other, whereas significant cues that relate to each other can be clustered to form a pattern.

"What other approach might help this patient to succeed?" The ability to look for alternatives by "thinking outside the box" is necessary because the need for creative problem solving occurs every day. Some examples of opportunities for nurse creativity are:

- Helping a patient who is dehydrated to drink more liquids by mouth
- Helping a patient newly diagnosed with diabetes learn appropriate foods for controlling blood glucose levels
- Finding alternatives for an IV tubing label when a traditional label is not available
- Finding something to write vital signs on when paper, laptop, or computer are not at hand
- Using tape and tongue blades to make a toy house for a young child.

Sometimes the best way to find a good alternative is to increase the number of options available. This is where creativity and reality meet in much the same way creativity is used to figure out how many words can be spelled using the letters in "nursing care." Initially, you may have minimal success, but after more thought, you will begin to "see" more possibilities and spell more words from these few letters. Nurses can promote creative problem solving if they begin with asking "What if we . . . ?"

Creative thinkers must have knowledge of the problem. They must assess the problems before them and use their knowledge (intellect) of both underlying facts and, in this case, principles of development that apply to this situation (see Clinical Example A). The nurse knows the anatomy and physiology of respiratory function and is aware of the purpose of incentive spirometry. The nurse also understands pediatric growth and development. In trying to assist the child, the nurse builds on this knowledge and comes up with a creative solution.

Evidence-Based Practice

Evidence-Based Competencies for Nurses

Problem

Evidence-based practice (the integration of research into practice), **clinical judgment** (the nurse's determination and provision of appropriate care to the patient), and patient preferences together ensure the use of scientific rigor when providing high-quality healthcare to patients. Although the benefits of evidence-based practice (EBP) have been well established, a lack of consistency exists in its use among healthcare providers, including nurses (Melnik et al., 2014).

Evidence

Clinicians fail to use EBP for several reasons, including provider lack of knowledge and understanding and the misperception that implementing EBP is time-consuming. These clinicians often follow traditional practices rather than evidence-based practices, because that's the way it's always been done, even when traditional practices have been proven to be harmful (Makic et al., 2013). Furthermore, many healthcare organizations fail to support EBP, and academic institutions continue to teach only traditional nursing methods. In order to begin implementing evidence-based practices, nurses must become proficient in critiquing current evidence, evaluating current practices, developing strategies to implement practice changes, and evaluating the outcomes related to changes in practice (Makic et al., 2013). To help combat clinicians' reluctance to implement evidence-based practices, the National Institutes of Health (NIH) has developed two programs: NIH Dissemination and Implementation (D&I) grants and the Improvement Science Research Network (Stevens, 2013).

Implications

Evidence-based practice has been an integral part of healthcare for at least a generation. Professional nursing and medicine strives to use this patient-centered practice methodology because it relies on the clinician's appraisal of the best evidence appropriate for the population the clinician serves. Furthermore, the added dimension of patient preference empowers the patient in healthcare decision making and allows the patient to be an active participant in his or her care as opposed to being the recipient of the traditional paternalistic physicians' orders or nursing interventions.

The National League of Nursing (NLN), the American Association of Critical-Care Nurses (AACN), and the Quality and Safety Education for Nurses (QSEN) have undertaken efforts to advance implementation of EBP among nurses at both the national and international levels (Melnik et al., 2014). Research by Melnik et al. (2014) supports both organizational and individual strategies for integrating EBP competencies into nursing practice, nursing research, organizational policies, management, and education.

Critical Thinking Application

1. How well do you understand EBP? Are you familiar with a health-care institution or a healthcare provider that uses EBP? How does their use of EBP affect patient satisfaction and outcomes?
2. In your own words, describe how EBP affects the care patients receive.
3. How will you integrate evidence-based care into clinical decision making in your professional nursing practice?

Clinical Example A

A pediatric home health nurse is caring for Tyesha, a 9-year-old girl who has ineffective respirations following abdominal surgery. The primary care provider has ordered incentive spirometry (a treatment device that promotes alveolar expansion). Tyesha is frightened by the equipment and tires quickly during the treatments. The nurse offers her a bottle of bubbles and a blowing wand. Tyesha is delighted with blowing bubbles. The nurse knows that the respiratory effort in blowing bubbles will promote alveolar expansion and suggests that she blow bubbles between incentive spirometry treatments.

Critical Thinking Questions

1. What questions might the nurse ask of Tyesha to isolate the reasons the incentive spirometry device frightens her?
2. How might the nurse explain the purpose of the incentive spirometry device to Tyesha in a way that would make her less frightened of it?
3. Why is blowing bubbles an effective form of treatment for Tyesha? How much does it depend on Tyesha understanding the therapeutic component of what she is doing?
4. If Tyesha didn't want to blow bubbles, what might an effective alternative be that could fulfill the same purpose?
5. If an older, teenaged child didn't want to use the incentive spirometry device, what might be an effective alternative for a child of that age?
6. How might the nurse measure the positive effect of Tyesha's blowing bubbles?

Inquiry

Inquiry, a form of research, is defined as a search for knowledge or facts. When a nurse uses inquiry, he or she examines objective information to gain clarification and find solutions to problems. Inquiry differs from query in that a query is simply a question that requires an answer. Critical thinking requires nurses to use inquiry to examine both the situation at hand and their own nursing practice: "Why do we always need to apply the dressing this way?" "How can I help a patient who is on a salt-free diet avoid problems with her serum potassium levels?" "Why do we always need to put gloves on when we give injections?" "What would happen if we helped the patient exercise more than twice a day?" "Is there something else we can try when a patient is having trouble swallowing?" Nurses continuously use inquiry in the clinical setting. Nurses are inquisitive decision makers who ask questions about physician orders they do not understand, seek more information about an alternative therapy, or wonder if there is a better way of accomplishing an outcome for a patient. Nurses make changes in their practice based on new information, evidence, or innovative ways of doing things better. Clinical inquiry can resolve clinical problems and issues to promote improved patient outcomes.

Reasoning

To be able to walk into a patient's room and immediately observe significant data, come to a conclusion about the patient, and begin appropriate actions takes clinical reasoning by an experienced nurse. To be objective, the nurse needs to focus on salient cues and not be influenced by personal beliefs, biases, or assumptions that can result in errors, as illustrated by this statement made by a nurse: "The patient's a man, so I didn't think he was really in enough pain for an injection of morphine."

To help determine if decisions are reasonable, nurses use one of two forms of logical reasoning. In **deductive reasoning**, the nurse works from the "top down" by starting with general ideas, observations, or principles and analyzing them to develop specific predictions (Polit & Beck, 2017). For example, based on prior knowledge, the nurse knows that older adults have increased susceptibility to infection (general). Using deduction, the nurse can predict that when an 88-year-old man arrives at the emergency department with a 2-day complaint of increased sputum production, decreased appetite, productive cough, low energy, and complaints of chest pain when coughing, he has pneumonia (specific). Ask these questions: "What is the general idea?" and "What cues observed support it?" and, finally, "Do the significant cues make sense? Are they logical?"

Inductive reasoning involves working from the "bottom up." The nurse observes specific behaviors or symptoms and develops a general conclusion by putting significant, specific cues together (Polit & Beck, 2017). For example, the nurse has observed the following specific symptoms in patients diagnosed with pneumonia: increased sputum production, poor appetite and fluid intake, productive cough, little energy, and complaints of chest pain with coughing. Using inductive reasoning, the nurse concludes that the presence of these same signs and symptoms in other patients strongly indicates they may also have pneumonia. Ask these questions: "What are the significant cues observed?" and "What is the conclusion from the cues (the end result)?" And again, "Does the conclusion make sense? Is it logical?"

During the process of reasoning, the nurse needs to determine if patient information is a fact, an inference, a judgment, or an opinion, as described in **Table 36-2**. Evaluating the credibility of information sources is an important step in critical thinking. Unfortunately, nurses cannot always assume that all the things they read or hear are facts. The nurse may need to ascertain the accuracy of information by reviewing the evidence (e.g., conducting a literature search), checking other documents (e.g., facility procedures), or talking with other informants (e.g., supervising nurse).

Clinical reasoning, the use of careful reasoning in the clinical setting to improve patient care, is a learned skill that novice nurses must practice. Clinical reasoning requires critical thinking and the ability to reflect on previous situations and decisions and evaluate their effectiveness. With effort and time, new nurses learn critical thinking and integrate it into daily routines. Here are a few actions new nurses can take to improve their clinical reasoning:

1. On entering a patient's room, look around and observe the patient, any other people in the room, where they

TABLE 36-2 Differentiating Types of Statements

Statement	Description	Example
Facts	Can be verified through investigation	Blood pressure is affected by blood volume.
Inferences	Conclusions drawn from facts; going beyond facts to make a statement about something not currently known	If blood volume is decreased (e.g., in hemorrhagic shock), the blood pressure will drop.
Judgments	Evaluation of facts or information that reflect values or other criteria; a type of opinion	It is harmful to the patient's health if the blood pressure drops too low.
Opinions	Beliefs formed over time; may include judgments that may fit facts or be in error	Nursing intervention can assist in maintaining the patient's blood pressure within normal limits.

are positioned in the room, and what they are doing. Observe what items, smells, and sounds are present and what actions are taking place. This is similar to doing a 60-second safety check, a 3-minute brief assessment, or a 5-minute general survey of the patient. Careful use of the senses can help the nurse collect important cues.

2. Common cues nurses learn to recognize include facial expressions, patient activity, degree of respiratory effort, smell of cigarette smoke, complaints made by the patient, bed safety (e.g., rails up or down, bed low and locked, call bell within reach), patient affect, colors (e.g., red indicating bleeding, yellow indicating infection). These common cues can provide meaningful information quickly and help the nurse determine which cues are salient and if they form a pattern. Clusters of information may bring attention to a problem or issue the patient is having (e.g., presence of infection) or that is in the patient's immediate environment (e.g., visitors preventing appropriate rest). The nurse can then determine the best course of action and intervene as appropriate (Koharchik et al., 2015).
3. The nurse can evaluate previous actions and turn those actions into experiences that can be drawn upon in the future. The new nurse may ask him- or herself questions about a situation in order to analyze and learn from the experience. For example, "How well did that work?" "How did the patient respond?" "What could be done better next time?"
4. Build awareness of faulty reasoning, an occurrence that may cause new nurses to make mistakes in reasoning. Types of faulty reasoning are outlined in **Table 36-3**.

Reflection

Reflection is the action of retrospectively making sense of occurrences, experiences, situations, or decisions and consequently learning from them. It is the process of figuring out what worked or did not work, what could have

TABLE 36–3 Types of Faulty Reasoning

Type of Faulty Reasoning	Action	Example
Bandwagon	Doing something because everyone else is doing it	Changing a patient's dressing without indicating date and time new dressing is applied because the dressing removed did not have this information.
Cause-and-effect fallacy	Linking something that happens to something that occurs before it happens	Thinking that the patient's nasogastric (NG) tube was draining fine until the nurse cleaned up the patient's bedside table; therefore, the nurse interfered with the NG tube drainage setup when cleaning up the bedside table.
Circular reasoning	Supporting an opinion by restating it using different words	Saying that a new dressing is very popular to use because a lot of nurses like using it. (The terms <i>popular</i> and <i>like using it</i> are saying the same thing.)
Either–or fallacy	Assuming that a problem has only two solutions	Thinking that the only way to help a patient with a headache is either with medication or a cold cloth on the head. (This ignores other interventions that may be helpful such as dimming the lights, decreasing noise, or giving the patient something to eat.)
Overgeneralizations	Coming to a conclusion when there is not enough evidence to do so	Concluding that a postoperative patient eats all of his meals based on the observation that he ate 100% of his last meal.
Using emotions instead of words	Reporting feelings about a situation rather than the facts	Saying the patient is an angry old man instead of saying that the older patient is anxious about being in the hospital.

been done differently to achieve better outcomes, what was done well, what necessary resources were available, and so on (Bulman & Schutz, 2013). To reflect on an experience, nurses need to learn to observe the significant factors of an experience that need to be included in reflective thinking. See **Box 36–1** >> for an example of guided reflection.

Evidence shows that debriefing, or reflective thinking after a simulated scenario, encourages reflective learning, a process that can help transfer book knowledge to practice application in complex situations (Decker et al., 2013). Reflective thinking can change a situation that is obscure, uncertain, and disturbing into one that is clear, understandable, and settled. For example, a nurse might be assigned to a patient who is anxious about going for surgery. The nurse can use guided reflection to help the patient “see” the surgical experience with better clarity, which may result in less anxiety for the patient.

Intuition

At times, nurses may experience what they call a “gut reaction” or a “feeling that something is wrong” when working with patients. Even though this awareness seems abstract and mysterious, it may be part of the nurse’s reasoning and analysis of the constant data the nurse receives through the senses below a level of conscious awareness. In their article “How Expert Nurses Use Intuition,” Benner and Tanner (1987) conclude that **intuition** is the use of nursing knowledge, experience, and expertise for understanding without the conscious use of reasoning. Many argue that intuition is a valuable cognitive skill in clinical decision making among professional expert nurses (Green, 2012; Pearson, 2013).

Intuition is a process. The data that are continuously received through senses are not always recognized consciously. Patterns and similarities of patterns are clustered and analyzed. Comparisons are made between a current patient’s significant patterns and past patients’ patterns

in response to similar situations. If the mind recognizes that a new pattern is similar to an old pattern, this recognition may bring the information to a level of cognitive awareness, making it available for the nurse to use in determining a course of action. Although the intuitive method of problem solving is gaining recognition as part of nursing practice, it is not recommended for new nurses or nursing students because they usually lack the knowledge base and clinical experience on which to make a valid judgment.

Courses are available to build critical thinking skills for nurses. For example, the National Council of State Boards of Nursing (NCSBN) has a continuing education course called “Sharpening Critical Thinking Skills.”

Critical thinking remains the cornerstone of nursing care and patient intervention. As nursing continues to evolve, so too do the methods of thinking that influence those interventions that directly affect patient care. Benner (2015) emphasizes shifting from critical thinking alone to multiple thinking methods that expand the nurse’s understanding and include understanding the patient’s experience, the family’s experience, and also the nurse’s experience. Benner reasons that the complexity of illness and its effect on the patient and all elements of his being beyond that of being a patient are too broad and far-reaching to be explained by a single theory. Benner recommends multiple methods of thinking in addition to critical thinking, including practical reasoning, in which decisions for actions are determined in part by the actions that provide the best outcome for the patient.

Clinical Decision Making

Nurses make many decisions every day:

- “Which patient should I see first?”
- “When can I teach my patient with congestive heart failure about a no-salt diet?”

Box 36–1

Guided Reflection

This activity illustrates how one new nurse reflected on a situation he encountered during a clinical day that caused him to think about what happened and how he responded. Learning to organize thinking

about patient care and professional nursing practice is an acquired skill. Reflecting on thinking processes supports recognizing the “lessons learned” for personal improvement in clinical judgment.

Task	Guided Reflection	New Nurse Response
Understanding the background of situation	<ol style="list-style-type: none"> 1. Briefly describe what happened and what emotions you experienced during the situation. 2. What previous personal experience with a similar situation helped guide you through the situation? 	<ol style="list-style-type: none"> 1. “I was so busy giving my patient his bath that I forgot to give him a scheduled medication.” 2. “I have worked as an unlicensed assistive personnel (UAP) in the past; I know that baths have to be given around other interventions that the patient has scheduled during the day.”
Observing	<ol style="list-style-type: none"> 3. What did you initially notice about the situation? 4. As time passed, what did you then notice? 	<ol style="list-style-type: none"> 3. “I started bathing the patient about 0850. I thought I had enough time to finish it, change his dressing, and then give him his medication that was scheduled to be given at 0930.” 4. “The patient needed more time than I thought to bathe. When I checked my watch, it was already 1003, and the medication was late.”
Interpreting	<ol style="list-style-type: none"> 5. What further information about the situation did you decide you needed, and how did you get it? 	<ol style="list-style-type: none"> 5. “I should have remembered that some patients, particularly older adults, need more time to do things. I could have started the bath earlier, or I could have given the patient his medication first, and then helped him with his bath.”
Responding	<ol style="list-style-type: none"> 6. What was your nursing response to the situation? What interventions did you do? 7. Describe stresses you experienced as you responded to the situation. 	<ol style="list-style-type: none"> 6. “I had to tell the charge nurse what had happened. I then had to give the medication late.” 7. “It stressed me out that I made a medication error. I felt stupid and was so embarrassed.”
Reflecting	<ol style="list-style-type: none"> 8. How did the situation end, and what emotion did you feel when the situation was over? 9. What might you do differently if this situation happens again? 10. What was your “take-away” from the experience? 	<ol style="list-style-type: none"> 8. “The patient received the medication 37 minutes late, so my actions didn’t negatively impact the patient, but I could have kicked myself for this.” 9. “I need to plan my work around medication administration times when I help a patient with morning care—or any intervention.” 10. “Keep an eye on the clock and give priority to interventions and activities I need to do at specific times—work the other interventions around the timed ones.”

Source: Based on Tanner, C. (2006). Thinking like a nurse: A research-based model of clinical judgment in nursing. *Journal of Nursing Education*, 45(6), 204–210. Retrieved from http://www.mccc.edu/nursing/documents/Thinking_Like_A_Nurse_Tanner.pdf.

- “How long should I wait before doing a bladder scan on my patient who hasn’t voided since the indwelling catheter was removed?”
- “When’s the best time for me to watch the video on that new dressing?”
- “Where can I find more linen for the UAPs to finish patient morning care?”

Wouldn’t it be nice if there was a book to show nurses how to guarantee all clinical decisions they make would be 100% “successful”?

Good decisions come from careful consideration of resources; potential alternatives and their potential outcomes; the nurse’s expertise, knowledge, skills, and clinical judgment; and the preferences of the patient. Typically, nurses make decisions during the process of solving problems. Types of decisions include:

- *Value decisions*, such as decisions regarding patient confidentiality
- *Time management decisions*, such as taking clean linens to a patient’s room when taking medication to be administered

- *Scheduling decisions*, such as bathing a patient before visiting hours
- *Priority decisions* about which interventions are most urgent and which can be delegated.

Nurses also assist patients in making decisions. When a patient is trying to make a decision about what course of treatment to follow, the nurse may need to provide information or resources the patient can use in making a decision (see the Lifespan Considerations section). Nurses also make decisions in their professional lives. For example, nurses must decide whether to work in a hospital or community setting, whether to join a professional association, and whether to carry professional liability insurance.

The constantly changing healthcare environment requires strong clinical decision-making skills. New technology, expanding roles for nurses in healthcare systems, the complexity of patients entering the healthcare system, and the expanding body of knowledge and skills all add to the complexity of clinical decision making.

When nurses do not have enough clinical experience or nursing knowledge, skills, or imagination to make decisions, they can turn to available guidelines for help. Decision trees and protocols can assist in decision making for many aspects of nursing and nursing subspecialties. For example, many facilities have an emergency protocol for starting a patient on low-flow oxygen when the patient meets listed criteria. Sometimes when cycling through the alternatives, one alternative will just be exactly what is needed and may be chosen for use without further consideration of other alternatives. Many models for decision making are available, each suggesting steps in how to use cognitive processes to choose among alternatives. The following common steps are used in making decisions:

1. Identify the situation or problem: What decision needs to be made?
2. List all possible alternatives and information about the situation (i.e., risks, consequences).
3. Compare pros and cons of each alternative or solution and evaluate all of them.
4. Select the best option or alternative to try in a given environment.
5. Put the alternative into action.
6. Evaluate the success of using the alternative or the best option (Decision Making Confidence, 2013).

As nurses apply critical thinking to challenges in the workplace, they typically must choose among possible alternatives, engage in problem solving, use the nursing process, employ the scientific method, and sometimes engage in trial and error.

SAFETY ALERT The Texas Board of Nursing (n.d.) recommends the following six questions as part of a decision-making model and a tool for clinical judgment in order to ensure patient safety:

1. Is the activity consistent with your state's Nurse Practice Act?
2. Is the activity appropriately authorized by a valid order or protocol, and is it in accordance with established policies and procedures?

3. Is the act supported by either research reported in nursing- and health-related literature or in scope-of-practice statements by national nursing organizations?
4. Do you possess the required knowledge and have you demonstrated the competency required to carry out this activity safely?
5. Would a reasonable and prudent nurse perform this activity in this setting?
6. Are you prepared to assume accountability for the provision of safe care and the outcome of care rendered?

Choosing Among Alternatives

Many clinical situations present possible alternatives that must be considered prior to taking action. In clinical situations, alternatives may be selected from a range of nursing interventions or patient care strategies. Often priorities for care suggest or even determine the alternative chosen, but not always. For example, pain may be treated with oral or injectable medications as needed (prn) or on a schedule, or without any pharmacologic intervention by using nursing measures to support the patient's comfort. In all cases, the nurse analyzes the alternatives to ensure that there is an objective rationale for choosing one alternative over another. For example, for the patient with kidney stone pain, common nursing measures may not provide strong enough relief, and oral medication may take effect too slowly, so an intravenous narcotic might be the best choice. The nurse must consider the possibilities of adverse consequences due to a decision. This is also part of the decision-making process. If the intravenous narcotic is selected, should safety measures such as a narcotic antidote and supplemental oxygen be in place? Think about the following questions when choosing between alternatives in decision making:

- | | |
|---|---|
| 1. Is there always just "one best" alternative? | Finding the "one best" alternative is very time consuming and may result in unnecessary delay. |
| 2. Can consideration always be given to every alternative? | The list of alternatives could be quite lengthy, so limit the list to the top five options for serious consideration. |
| 3. Is there always time to gather all the information about alternatives and consequences and then to think about them one at a time? | Is there ever enough time? |

The nurse recognizes significant cues that form patterns and then uses intellect, intuition, and reasoning to quickly make decisions and choose a plan of action based on past experiences. Experienced nurses will recognize more patterns and possess a greater wealth of knowledge, enabling them to come to decisions quickly. Regardless of experience, all nurses cycle through alternatives until they find an appropriate choice based on their past experience,

knowledge, and skills. At this point, the nurse mentally rehearses the choice and, if the alternative looks like it will work, selects a course of action. Every decision-making process helps nurses improve their decision-making skills and adds to their clinical experience.

Problem Solving

Problem solving is the norm rather than the exception for routine nursing responsibilities today. Nurses become skilled problem solvers in order to manage obstacles and maintain an unencumbered flow of care as they manage their workday. Sometimes patients are scheduled to be in two places at one time for various diagnostic tests, or perhaps a patient received the wrong diet tray and needs a different diet meal, or a patient needs a medication that has yet to arrive from the pharmacy department. Sometimes the problem itself is the number of problems that must be addressed in a short amount of time. Because some patients have complex health issues, their care is equally complex and involve problems that are not always easy to “fix.” Some problems may occur repeatedly—for example, the nurse may realize that the pharmacy has been late delivering medications for several days. Nurses must be alert to recurrent problems and new problems and find the time to step in and correct the cycle (see the module on Quality Improvement for more information).

When problems arise, nurses use decision making as part of the problem-solving process. In problem solving, the nurse obtains information that clarifies the nature of the problem and identifies possible solutions. The nurse then carefully evaluates the possible solutions and chooses the best one to implement. After implementing the solution, the nurse monitors the situation over time to ensure the initial and continued effectiveness of the solution. The other possible solutions are held in reserve in the event that the first solution is not effective. The nurse may also encounter a similar problem in a different patient situation where another solution is found to be the most effective. Therefore, problem solving for one situation contributes to the nurse’s body of knowledge for problem solving in similar situations. Commonly used approaches to problem solving include the nursing process, trial and error, intuition, and the scientific method.

The Nursing Process

The nursing process includes five phases that organize the problem-solving process (see Exemplar 36.A on the Nursing Process for more information). Nurses make clinical decisions using critical thinking during every phase of the nursing process. Experienced nurses also use their experiences, knowledge, skills, and current nursing research evidence to make decisions. As nursing students’ knowledge, skills, and attitudes progress, they will be able to make better decisions faster using the nursing process as a decision-making tool. Clinical Example B outlines the five phases of the nursing process as they related to problem solving:

Clinical Example B

1. **Assessment:** *Gathering information to determine the problem*
The nurse admits a 4-year-old patient, Austin Gates, who is suspected of having asthma. The patient has a history of frequent colds and has an allergy to grasses. His dad smokes three packs of cigarettes a day. Austin’s mother tells the nurse that Austin has been playing with the neighbor’s cats for the past few days. The nurse determines it is important to assess Austin for shortness of breath, respiratory effort, use of accessory muscles, lung sounds, vital signs, oxygen saturation, and the results of lab studies, including a complete blood count (CBC) and chest x-ray. With the help of Austin’s mother, the nurse collects other data that may be relevant, such as the patient’s past medical history, developmental behaviors, and activity level.
2. **Nursing Diagnosis:** *Stating the specific problem to solve*
Based on the assessment data obtained, the nurse caring for Austin determines that his main complaint is difficulty in breathing secondary to airway obstruction. The obstruction is caused by both narrowing of airways and increased mucus production, evidenced by audible wheezing and adventitious lung sounds. The patient is anxious secondary to his shortness of breath and being in a strange environment. The patient has an elevated WBC and an increased respiratory rate. The nurse must decide which of these symptoms are top priorities for nursing care.
3. **Planning:** *Stating how to know when the problem is resolved*
During the planning phase, the nurse caring for Austin decides that an important priority would be to monitor his wheezing, which indicates patency of airways. The goal might be “Austin’s lung sounds will be clear bilaterally.”
4. **Implementation:** *Giving solutions to resolve the problem*
Interventions to help Austin meet his goal might be:
 - Assess lung sounds every 4 hours
 - Maintain supplemental oxygen via nasal cannula as ordered by physician
 - Administer medication prescribed by provider
 - Encourage oral (PO) fluids.
5. **Evaluation:** *Evaluating if the problem has been resolved*
Nursing staff has documented “For the past 12 hours, Austin’s lung sounds have been free from wheezes and are now clear.”

Critical Thinking Questions

1. What interventions must the nurse address immediately in caring for Austin?
2. What interventions can be delayed?
3. What actions should the nurse anticipate related to Austin’s presentation?

Trial and Error

One way to solve problems is through trial and error—trying out a solution, seeing if it works, and, if it does not, reflecting on why and making another, different attempt. Trial and error is an option only when time and safety allow multiple opportunities to select the correct solution. This problem-solving process is not an option when an error may result in harm to the patient. Trial and error may be more useful in situations related to patient comfort or preference. Two trial-and-error examples are when determining how far to raise the head of the bed for the patient to be comfortable enough to eat, or trying different methods to communicate

with a patient who has a hearing impairment. The trial-and-error process is primarily used to solve problems; it may not result in the best solution, but it may reveal a workable solution. The use of trial and error requires creativity and patience, two qualities essential to nursing.

Intuition

Intuition is an unconscious awareness of a potentially compromising or dangerous situation. Intuition is an aspect of critical thinking. It is also relevant to problem solving. With practice, solving problems using rules and anticipatory thinking transforms into the ability to use thinking processes, knowledge, and intuition almost unconsciously.

The Scientific Method

The scientific method of problem solving is a formalized, logical, systematic investigative approach that is most successful when working in a controlled situation. Health professionals, often working with individuals in uncontrolled situations, require a modified approach to the scientific method for solving problems. For example, unlike experiments with animals, the effects of diet on health are complicated by a patient's genetic variations, lifestyle, and personal preferences.

Many aspects of nursing practice involve clinical decision making. Any time a patient's condition changes, those caring for the patient must decide how to respond. Decisions are usually made by problem solving or by choosing among alternatives. Some actions are performed routinely, such as measuring vital signs at the beginning of the shift or introducing oneself when meeting a new patient. Other actions require careful consideration, critical thinking, problem solving, and decision making in order to provide the highest quality nursing care and assure the safety of patients and staff. See Clinical Example C for an example of clinical decision making.

Clinical Example C

Anna Nadine, 64 years old, is admitted to the medical unit at a local healthcare facility with a medical diagnosis of pulmonary edema secondary to left-sided heart failure. Ms. Nadine has a history of type 2 diabetes requiring insulin injections, hypertension, and early-stage chronic renal failure. She is married, has no children, and lives with her husband in a high-rise apartment building that has a functioning elevator. Initial vital signs are T_O 99.2°F, P 90 bpm, R 24/min, and BP 136/86 mmHg. Oxygen saturation (O_2 Sat) is 91% on room air. Ms. Nadine is 5'2" and weighs 168 pounds. She has the following physician orders:

- Vital signs, including oxygen saturation every 1 hour \times 3, then every 2 hours \times 3, then every 4 hours
 - Give oxygen at 2 LPM via nasal cannula
 - Chest x-ray
 - Electrocardiogram (ECG)
 - Lab work: CBC with differential, electrolytes, urinalysis (voided)
 - ABGs on oxygen
 - Daily weights
 - No-added-salt regular diet
 - Accu-Chek before meals and at bedtime, with sliding scale—cover with regular insulin
- 200 or less = 0 coverage
 201–250 = 2 units subcutaneous injection
 251–300 = 4 units subcutaneous injection
 301–350 = 6 units subcutaneous injection

351–400 = 8 units subcutaneous injection
 401 and higher = 10 units subcutaneous injection and call physician

- Activity—out of bed to chair with assistance
- Intake and output every 12 hours
- D_5 $\frac{1}{2}$ NS with 10 mEq potassium chloride (KCl) at 50 mL/hr
- Lasix 40 mg IV STAT, then Lasix 20 mg PO daily (am)
- Digoxin 0.125 mg PO daily (am)
- Clonidine 0.1 mg PO BID.

Within 12 hours of admission, Ms. Nadine's weight is 160 pounds, and she is breathing more comfortably with breath sounds mostly clear with some fine crackles in the bases. Vital signs are T_O 99.2°F, P 78 bpm, R 18/min, BP 118/80 mmHg, and O_2 Sat 97% on 2 LPM via nasal cannula.

The next day when you return to the unit and are again assigned to her care, you receive a report from the previous shift that Ms. Nadine has been confused and disoriented for the past 2 hours. Her blood sugar when last checked 30 minutes ago was within normal limits. Her husband has been notified and plans to come in and sit with her today, but he has not yet arrived.

Critical Thinking Questions

1. What assessment information do you need to obtain?
2. What are the top three priority nursing actions for Ms. Nadine at this time?
3. What factors could be contributing to Ms. Nadine's confusion?
4. How important is it to gather additional assessment data prior to implementing any interventions for Ms. Nadine?
5. What discussion might you want to have with Mr. Nadine when he arrives?
6. Use critical thinking to determine what physician orders you would anticipate receiving for Ms. Nadine.

Clinical Judgment

The end product of the complex process that is clinical decision making is clinical judgment, the nurse's determination and provision of appropriate care to the patient. In other words, clinical judgment combines critical thinking abilities, evaluative decision making, and nursing experience to determine appropriate responses to a patient's complex and often layered situation to achieve the best patient outcomes (Thompson et al., 2013). Clinical judgment can be used in emergency situations and also for long-term planning of care.

This dynamic cognitive process brings all the elements of critical thinking and clinical decision making together in making clinical judgments about patient care through the application of nursing knowledge, skills, and attitudes. New nurses may find this skill difficult and slow to use, whereas experienced nurses will be faster and will be able to use their intuition for clinical judgment. The National League for Nursing (2016) lists nursing judgment as a competency for graduates of nursing programs. The National Council of State Boards of Nursing (2016) has models available for states to use in revising their scopes of nursing practice that relate to the accountability for clinical judgments. According to NANDA International (NANDA-I) (2016), a nursing diagnosis is a clinical judgment about an individual or family's situation or their response to a health concern or life process. Three nurse researchers have given the nursing profession important clinical research evidence related to clinical judgment: Patricia Benner, whose skill acquisition model describes five levels of clinical competence; Christine Tanner, whose clinical judgment model supports "thinking like

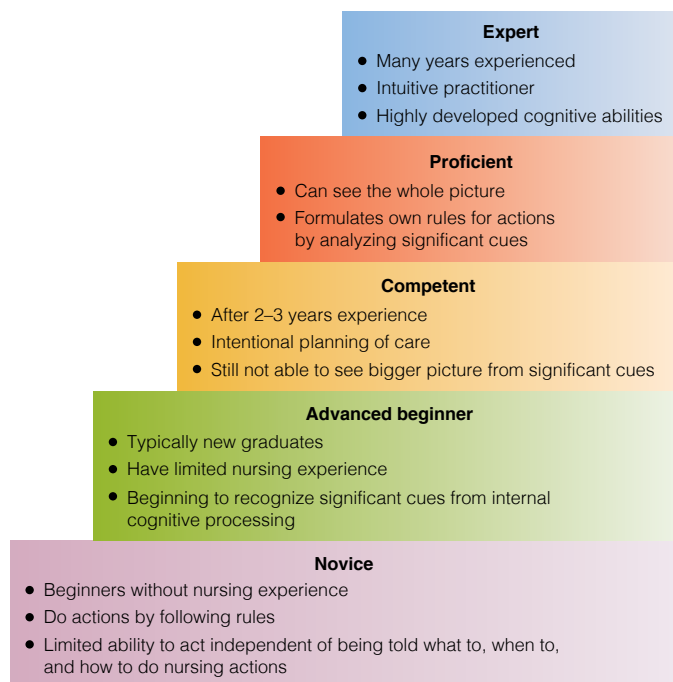

a nurse;" and Kathie Lasater, who promotes the use of a clinical judgment rubric.

Benner's Skill Acquisition Model

The ability to make clinical judgments improves as nurses gain experience and build on their critical thinking and decision-making skills. A study in the late 1970s compared the performance of senior nursing students, new nurses, and experienced nurses over a 3-year period of time. The results of this study demonstrated distinct differences in clinical performance at these varying levels of nursing education and nursing experience (Benner, Tanner, & Chesla, 2009). Benner adapted these findings to the Dreyfus Model of Skill Acquisition and organized the evidence from the study into five levels of proficiency a nurse progresses through as he or she gains additional clinical experience (Benner, 2011). These levels are novice, advanced beginner, competent, proficient, and expert (see **Figure 36-3** »).

The different levels of competence reflect four progressive changes in thinking processes:

1. Moving from not having nursing experiences on which to relate to having concrete clinical experiences to relate to new situations that require critical thinking
2. Progressing from following steps in a specific sequential order to customizing and adapting actions using nursing experience and intuition
3. Moving from taking in many significant cues and trying to make sense of all of them to identifying significant cues and clustering them to form patterns
4. Progressing from being an observant bystander to being an active participant.

Source: Data from Benner, P. (2011). From novice to expert. *Current Nursing*. Retrieved from http://currentnursing.com/nursing_theory/Patricia_Benner_From_Novice_to_Expert.html.

Figure 36-3 » Benner's five levels of clinical competence from nursing student to graduate to professional.

Each level builds on the previous level as critical thinking skills are mastered and decision making becomes routine for the nurse. Experience further expands this process as the nurse gains confidence in his or her nursing skills.

Tanner's Clinical Judgment Model

Clinical judgment does not always include standard decision making or require all the skills of critical thinking. Tanner's "thinking like a nurse" approach in her clinical judgment model emphasizes the importance of elements the nurse uses in cognitive processing: different types of knowledge (e.g., textbook, transferred, on-the-job, abstract), length of nursing experience, values, morals, intuition, and knowing the patient (i.e., being familiar with expected patterns of responses to a medical condition or knowing the individual patient) (Tanner, 2006). Another element that influences clinical judgment is the culture of the work environment, including group norms and expectations of work routines. The Tanner model includes four features: noticing, interpreting, responding, and reflecting (**Table 36-4** »).

Nursing education teaches fundamental nursing knowledge, skills, and attitudes that lay the foundation for expected high-level performance from students. Nursing education, both didactic and clinical, promotes safe and quality nursing performance. Nursing programs teach students to develop knowledge of their patients in order to care

TABLE 36-4 Features of the Tanner Clinical Judgment Model

Feature	Description
Noticing	<ul style="list-style-type: none"> ■ Having a sense of what is happening in the patient situation ■ May include recognition of or absence of expected significant cues from the patient's response to illness or a medical condition ■ Includes influences of the nurse's own health beliefs about patient situations and expectations of the work culture for patient care
Interpreting	<ul style="list-style-type: none"> ■ Using logical reasoning to gain understanding about a situation and determine appropriate actions
Responding	<ul style="list-style-type: none"> ■ Includes analyzing a situation and choosing the best course of action ■ Includes intuitive "knowing" from past similar experiences ■ Includes using past similar experiences to "make sense" of a present clinical situation ■ Includes responsive actions by the nurse
Reflecting	<ul style="list-style-type: none"> ■ Using cognitive processes to review a clinical situation ■ Considering appropriateness of assessment data obtained in the situation, actions taken, and positive and negative outcomes for patient ■ Making mental response adjustments for similar future situations ■ Learning from actions (done or not done)

Figure 36-4 » Tanner's clinical judgment model includes four major sequential cognitive steps: (1) noticing, (2) interpreting, (3) responding, and (4) reflecting.

for them responsibly and to develop a sense of their patients' situations in which they will need to intervene. Reflecting on clinical situations and learning from them help students build experiences they can use for future reference. In other words, "thinking like a nurse" begins with learning as a nursing student (Tanner, 2006). See **Figure 36-4** » for a diagram of these sequential cognitive steps.

Lasater's Clinical Judgment Rubric

Lasater developed the clinical judgment rubric to measure and evaluate clinical judgment using simulation (Bussard, 2015). Tanner's clinical judgment model served as the foundation for the rubric (see Figure 36-4). The rubric serves as a guide for learners to know the specific characteristics needed to reach quality levels of clinical judgment performance (**Figure 36-5** »). The rubric has been used successfully while observing learners in a simulation environment.

The rubric uses the four aspects of the Tanner model: noticing, interpreting, responding, and reflecting. Lasater developed additional dimensions for each of these aspects to describe associated behaviors and actions for each (see Figure 36-5, the vertical axis): for example, prioritizing data is an essential behavior of *interpreting* information. Lasater proposes measuring the four aspects of Tanner's model in a progressive developmental order: beginning, developing, accomplished, and exemplary (see Figure 36-5, the horizontal axis). The table provides descriptors and behavioral dimensions for each performance level. Students can use the rubric to measure their progress in

using clinical judgment. The rubric clearly defines characteristics for clinical judgment levels and dimensions (Bussard, 2015).

Focus on Integrative Health Holistic Care and Autonomous Decision Making

Western medicine has long supported paternalistic management of healthcare decision making, often relegating most patients to a passive state in decisions about their health. Brophy (2014) writes that while all providers acknowledge a patient's right to self-determination, patient autonomy has been limited in traditional Western medicine. The integration of complementary medicine and holistic care into the U.S. health-care system has altered patient healthcare decision making by supporting patient autonomy and the holistic relationship between the patient and the holistic-care provider.

Self-governance is the foundation of holistic care and autonomous decision making. Patients grounded in traditional paternalistic healthcare management will find that holistic providers spend time educating, building patient knowledge, and probing to ensure patient understanding in order to enable the patient to make the best decisions for his or her health. Holistic decision-making models are based on biopsychosocial, patient-centered, informed, and shared decision making, and evidence-based patient choice decision-making models in which patient-provider interactions focus on the whole person, not the disease.

Progressive Development				
Dimensions	Beginning	Developing	Accomplished	Exemplary
<u>Noticing</u> <ul style="list-style-type: none"> Focus on significant cues Recognize differences Look for cues 				
<u>Interpreting</u> <ul style="list-style-type: none"> Prioritize data Make sense of data 				
<u>Responding</u> <ul style="list-style-type: none"> Calm and confident Clear communication Do planned actions Skill abilities 				
<u>Reflecting</u> <ul style="list-style-type: none"> Evaluate/analyze self Desire to be better

Figure 36–5 » Lasater used the dimensions from Tanner’s clinical judgment model and created developmental levels of clinical judgment for her rubric.

Lifespan Considerations

Clinical Decision Making Involving Children

Parents often make decisions about the healthcare of their children. Growing children can participate in those decisions in developmentally appropriate ways. As children mature and develop, they gain decision-making ability and an understanding of the consequences of their decisions. They are able to contribute to decisions about their health; however, healthcare providers must carefully evaluate and follow an established process if the child is involved in making his or her health-care decisions (Michaud et al., 2015). Children’s ability to reason and think critically about themselves and their situation develops gradually. At each stage, nurses should be aware of the way children think and should be sensitive to how the child can be involved in healthcare decisions at each developmental stage:

- Infants progress from reflexive behavior to simple, repetitive behavior and then to imitative behaviors, learning the concepts of cause and effect and object permanence. Infants are not involved in healthcare decision making, but they need to be comforted and feel secure throughout the entire healthcare process, including during waiting periods.
- Toddlers and preschoolers are egocentric and engage in magical thinking. They cannot reason out the implications of care, but they need explanations in language they can understand. Play therapy and use of dolls and toys can help children in this age group understand healthcare in a manner appropriate to their developmental stage. Toddlers and preschoolers can sometimes be given options (e.g., “Do you want your dressing changed before breakfast or after?”).

- School-age children tend to be concrete thinkers. They benefit from simple, direct explanations; hands-on exploration of equipment and materials; and helping the care provider as appropriate during procedures. Involving these children in care can increase cooperation and decrease anxiety.
- Adolescents are able to think abstractly and are able to participate in healthcare decisions. Adolescent involvement in clinical decision making is complex and, when possible, should involve the patient’s assent to a procedure, though parental consent is still required. In some instances, an adolescent may provide assent as well as possess autonomous decision-making ability for clinical care. In such cases, the adolescent is also afforded both confidentiality and the ability to provide consent for procedures (Michaud et al., 2015). Healthcare providers, and if required, attorneys, must evaluate the adolescent and determine that he or she is competent and capable of making informed decisions.

Clinical Decision Making Involving Pregnant Women

Three decision-making models prevail in the health of the pregnant woman: paternalism, consumerism, and mutualism (Cox, 2014). Paternalism assumes that the provider, because of education and experience, knows best and will make the best decisions for the woman and the fetus. This assumption is based on the further assumption that the provider will make the best decision because of the need for a positive reputation among present and future patients.

The consumerism model takes a hands-off approach to decision making on the part of the clinician. In this model, the woman or her insurance provider pays for a service. The provider gives the woman what he or she believes is the best

information based on science and research. There is a transfer of essential information, enabling the woman to make an informed decision, but there is little engagement.

Mutualism is the most complex of the three models and involves shared decision making between the woman and her healthcare provider. In the mutualism model, the provider gives the woman information regarding any decision that must be made. The woman informs the provider of her preferences, values, expectations, previous knowledge, and other factors that may influence her decision making. In turn, the provider molds the information from the general to the specific as it relates to the unique individual woman and her pregnancy. Together, the patient and the provider discuss scenarios and options, deliberate, and arrive at a mutual decision.

Two examples of situations that require mutual decision making between the childbearing woman and her healthcare provider are women who have previously undergone cesarean section but wish to consider a trial of labor after cesarean (TOLAC) (Cox, 2014), and women who prefer intermittent fetal monitoring during labor in contrast to constant fetal monitoring that requires bedrest. In these cases, as in others, women should be informed of risks, benefits, evidence, possible occurrences, and support measures (Hersh, Megregian, & Emeis, 2014). Mutualism and shared decision making provides the best model for managing these and other issues related to pregnancy, labor, and delivery.

For the childbearing woman, pregnancy, labor, and delivery can be intense times. Women value the input of providers; yet, some women have described providers as inadequate, insensitive, and coercive. Childbearing women expect providers who are both knowledgeable and sensitive and who value their patients' input in decision making about their bodies, their lives, and the lives of their unborn children.

Clinical Decision Making Involving Older Adults

All adult patients should be involved in clinical decision making and planning their nursing care; however, older adults with impaired cognition related to disease processes such as Alzheimer disease present a challenge. The nurse should allow these patients as much control and input as possible, keeping discussions simple, direct, and easy to understand. Older adults with impairments usually are unable to perform multiple tasks or to think of more than one step at a time. The nurse must be willing to calmly repeat instructions as necessary. Presenting and discussing issues in basic terms helps maintain the older adult's respect and dignity and allows older adults to participate in their care for as long and as much as possible. If the older adult is unable to perform self-care activities such as bathing or health-related activities such as dressing changes, the nurse should seek appropriate alternative methods for assisting the patient with these tasks.

Concepts Related to Clinical Decision Making

Clinical decision making is a complex process in which nurses observe and gather data, interpret that data through the use of salient cues, and identify patterns that provide critical information. Nurses analyze cues and patterns and determine

patients' priority needs. Nurses also evaluate alternatives to provide appropriate interventions to support best outcomes for patients. The nursing process is the professional process by which nurses engage in clinical decision making.

Clinical decision making impacts every action and intervention performed by the professional nurse for every patient who experiences an alteration from his or her usual state of health. Clinical decision making is integral to nursing: it affects quality of care, patient satisfaction, cost, and care-related outcomes. Nurses make critical decisions and intervene to maintain the essential states necessary for life: airway, breathing, and circulation (ABC). Rapid clinical decisions and interventions maintain a patient's airway, ventilation, and perfusion, as well as the patient's oxygen supply to meet the body's demands. The nurse's clinical decision to initiate cardiopulmonary resuscitation (CPR) immediately can help restore circulation to major organs, including the brain and the heart. Nurses' critical decision making addresses the patient's actual or potential risk for compromised airway that may lead to respiratory arrest and alteration in the body's acid-base balance.

The nurse uses a vast body of knowledge in deciding appropriate interventions to resolve dehydration for the patient with fever in order to restore the patient to a state of normal hydration and to minimize the patient's electrolyte imbalance. However, the nurse's decisions and interventions must also reflect caution to avoid causing fluid overload that may exacerbate heart failure, compromise circulatory perfusion, and lead to respiratory failure.

The nurse caring for patients with neurologic deficits makes clinical decisions that reduce environmental stimuli with the potential to increase the patient's intracranial pressure. The nurse makes clinical decisions that avoid overwhelming the patient's sensory perceptions.

Nursing clinical decision making is integral to the postoperative patient, as the nurse's decision-making capability leads to interventions that assist patients who required surgical intervention for an inflammatory process, who undergo an orthopedic procedure related to mobility or orthopedic function, or have alteration in cellular regulation such as breast or colorectal cancer. The nurse uses knowledge and clinical decision making to perform interventions to decrease pain and promote patient comfort while continually assessing the patient and noting any postoperative alterations, including fever, a possible sign of infection; urinary retention after removal of an indwelling urinary catheter; or gastric alterations, a possible sign of digestive system complications that may compromise the patient's nutritional status. All hospitalized patients have increased risk of infection. Nurses' clinical decisions about a patient's already compromised immunity or recent surgery can alter the patient's risk of exposure to infection. Nurses' clinical decisions and interventions in the postoperative patient include interventions to promote tissue integrity and wound healing at the surgical site.

Almost every patient-nurse encounter requires a clinical decision that draws on the nurse's academic knowledge and work experience. Patients who benefit from nurses' sound decision-making ability experience satisfaction with quality nursing care. The Concepts Related to Clinical Decision Making feature links some, but not all, of the concepts integral to clinical decision making. They are presented in alphabetical order.

Concepts Related to Clinical Decision Making

CONCEPT	RELATIONSHIP TO CLINICAL DECISION MAKING	NURSING IMPLICATIONS
Accountability	Standards of care set benchmarks for nursing performance expectations, including evidence of competent and effective clinical decision making that reflects professional behavior.	<ul style="list-style-type: none"> Nurses are responsible for the clinical decisions and judgments they make to support desired patient outcomes.
Cognition	The nurse assesses the cognitive ability of the patient and determines the severity of cognitive impairment. Based on this assessment, the nurse decides on the most effective way to communicate and to teach the patient.	<ul style="list-style-type: none"> Nurses are knowledgeable about the progression of cognitive impairment. Based on the patient's history and the nurse's assessment, the nurse decides on those interventions that have been found to be effective means of communicating and teaching patients who are cognitively impaired. The nurse creatively employs those methods.
Collaboration	The nurse's assessment determines the patient's post-discharge needs, which may include the need for subacute care; visiting nurse services for wound care, vital sign monitoring, teaching, and safety assessment; and the need for home physical therapy.	<ul style="list-style-type: none"> Nurses participate in a collaborative team approach when caring for patients. Nurses refer patients to social services and case management to provide services outside of the hospital while continuing certain interventions for goal attainment.
Communication	Priorities of patient care need to be communicated to achieve continuity of care. Passing on correct information about patient status helps nurses on the next shift make competent decisions about patient care.	<ul style="list-style-type: none"> Nurses use the patient's plan of care, written or electronic, to communicate priority goals of the patient; document treatments, interventions and outcomes, and teaching; and record their work.
Safety	All clinical decisions, actions, and intervention on the part of the nurse must protect patients from harm. Clinical decision making and nursing actions and interventions must protect the nurse and nursing colleagues from harm.	<ul style="list-style-type: none"> Protecting patients from harm, or nonmaleficence, is one of the ethical foundations of nursing care. Behaviors that endanger the nurse, nursing colleagues, and staff increase the risk of serious injury, loss of staff members due to injury, and possible health repercussions such as needlesticks and back injuries.
Thermoregulation	Patients with thermoregulatory dysfunction require immediate interventions to begin cooling and minimize organ and brain injury in cases of hyperthermia and immediate warming for patients with hypothermia to minimize tissue injury, loss of limb, or in cases of extreme exposure, death.	<ul style="list-style-type: none"> The nurse is knowledgeable about the need for immediate interventions and the necessary precautions in treating patients with exposure and thermoregulatory disorders. This knowledge, in combination with patient assessment, helps the nurse make appropriate decisions about the independent actions the nurse will take.

Focus on Diversity and Culture

Double Minority and Patient–Provider Relationships

Shared clinical decision making, the combination of clinical expertise and patient values and preferences, is an important part of the patient–provider relationship. Patients who belong to more than one minority group, for example patients who identify as lesbian, gay, bisexual, or transgender (LGBT), and also identify with an ethnic or cultural minority, are at risk for suboptimal shared decision making (DeMeester et al., 2016; Peek et al., 2016), which often results in poor clinical outcomes (Harvey & Housel, 2014). Patients describe healthcare providers' lack of knowledge regarding gender identity, cultural barriers, and distrust as factors that contribute to

stigmatization and discrimination in the healthcare system. DeMeester et al. (2016) provide an extensive list of components for both patients and providers to assist in overcoming barriers to shared decision making for double-minority individuals. Peek and colleagues (2016) developed a model that depicts how race, gender identity, and other factors influence shared decision making. Shared decision making can help break down barriers between providers and patients to help increase trust and improve clinical outcomes.

REVIEW The Concept of Clinical Decision Making

RELATE Link the Concepts

Linking the concept of clinical decision making with the concept of legal issues:

1. What legal actions may occur if the nurse fails to make prudent clinical decisions? Explain your answer.
2. What role regarding sound clinical decision making in patient care is expected of the licensed registered nurse?
3. What role regarding sound clinical decision making in the workplace does the employer expect of the nurse?

Linking the concept of clinical decision making with the concept of evidence-based practice:

4. The nurse with strong critical thinking maintains an evidenced-based practice by _____.
5. A nurse reads a peer-reviewed article that recommends changing currently accepted practice. What critical thinking will the nurse perform before accepting the article's recommendations?

Linking the concept of clinical decision making with the concept of ethics:

6. What ethical obligation does the nurse hold toward the patient related to clinical decision making?
7. What ethical obligation does the nurse hold toward the hiring facility related to clinical decision making?

REFLECT Apply Your Knowledge

The nurse is caring for a patient who was admitted 3 days ago with acute abdominal pain. Following extensive diagnostic testing, the patient has received a medical diagnosis of stomach cancer, with suspected metastasis to the liver and pancreas. The oncologist has informed the patient that there are several options related to treatment. Option 1 is to surgically remove as much of the tumor as possible, followed by chemotherapy and radiation therapy. This is the most aggressive approach with the best odds for survival, but the oncologist tells the patient that with the amount of metastasis that has already occurred, the odds for survival are still not very good (less than 10%). The second option is to do nothing, allowing the patient to remain as comfortable as possible (palliative care) until death, which will likely occur in 3–6 months. The third option is the moderate option and involves chemotherapy to slow cancer growth, which may prolong the patient's life but will result in side effects (e.g., hair loss, vomiting, weakness) that will likely impact the patient's quality of life. After the oncologist leaves the room, the patient looks to the nurse and asks, "What do you think I should do? What would you do if you were me?"

1. What actions by the nurse would be most appropriate for this patient?
2. What ethical, legal, and moral duties guide the nurse when responding to this patient's questions?
3. How would you respond to each of the patient's questions?

Exemplar 36.A The Nursing Process

Exemplar Learning Outcomes

36.A Analyze the nursing process as it relates to clinical decision making.

- Describe the assessment phase of the nursing process.
- Describe the diagnosis phase of the nursing process.
- Describe the planning phase of the nursing process.
- Describe the implementation phase of the nursing process.
- Describe the evaluation phase of the nursing process.
- Differentiate the use of the nursing process in caring for patients across the lifespan.

Overview

The **nursing process** is used to identify a patient's health status and actual or potential healthcare problems or needs, to establish plans to meet the identified needs, to deliver specific nursing interventions to meet those needs, and to

evaluate the success of those interventions. The patient may be an individual, a family, or a group.

The nursing process gained legitimacy in clinical practice in 1973 when the phases of the nursing process were included in the American Nurses Association (ANA) *Standards of Nursing Practice*. The standards of practice within the

Figure 36-6 » The nursing process in action.

most current *Scope and Standards of Nursing Practice* include five phases of the nursing process: assessment, diagnosis, planning, implementation, and evaluation (American Nurses Association, 2010a). Outcome or outcome identification is sometimes included as another phase of the nursing process; however, in this text, outcomes are used to evaluate the patient's response to the plan of care. Virtually every state has since revised its nurse practice acts to reflect the nursing process. See **Figure 36-6** » for an illustration of the nursing process.

A few general characteristics of the nursing process complement its ease to organize the flow of nursing care and produce an individualized plan of care for all patients across the lifespan. The nursing process is a *dynamic* rather than static plan that can adapt to changes in the patient's status. The nursing process is *patient-centered*. The nurse organizes the plan of care according to a patient's need to achieve goals and outcomes.

Health is more than the absence of disease: it incorporates physical, spiritual, and emotional well-being. The nurse takes a holistic view of the patient and collects data related to the biological, psychologic, psychosocial, socioeconomic, and spiritual aspects of the patient. In other words, a holistic view sees the patient as the whole person rather than just the illness.

The nursing process is an adaptation of problem solving used by those involved with patient care. For example, physicians use the medical model, which focuses on physiologic

systems and the disease process. The nursing process is directed toward a patient's responses to the disease process and to the effects of the disease process, interventions, and therapies that interrupt the patient's standard of functioning in various aspects of his or her life. The nursing process assists the patient in restoring both physical health and general well-being within the limits of the patient's health condition.

Decision making is involved in every phase of the nursing process. Nurses can be very creative in making decisions to facilitate the individualized plan of care for each patient. The nursing process is interpersonal and *collaborative*; it requires the nurse to communicate directly and consistently with patients and families to meet their needs. The nursing process also requires that nurses collaborate with other members of the healthcare team in a joint effort to provide quality patient care. The universal characteristics of the nursing process make it an amenable framework for nursing care in all types of healthcare settings and with patients of all age groups, ethnicities, religions, cultures, genders, and sexual orientations.

An overview of the five phases of the nursing process is given in **Table 36-5** ». The phases of the nursing process are not separate entities—they are interrelated and they overlap. For example, assessment, which may be considered the first phase of the nursing process, is also carried out during the implementation and evaluation phases. For instance, while administering medications (implementation), the

TABLE 36–5 The Phases of the Nursing Process

Phase and Description	Purpose	Activities
Assessment		
Collecting, organizing, validating, and documenting patient's assessment data Begin noting significant cues and how they may be clustering.	To establish a database about the patient's response to health concerns or illness and the ability to manage healthcare needs.	<ul style="list-style-type: none"> ■ Establish a database: <ul style="list-style-type: none"> — Obtain a nursing health history. — Conduct a physical assessment. — Review patient records. — Speak with family members and significant support persons. — Speak with appropriate health professionals. ■ Update data to keep it current.
Look for significant cue clusters and patterns.		<ul style="list-style-type: none"> ■ Organize data.
Seek more assessment data to clarify cue clusters and patterns.		<ul style="list-style-type: none"> ■ Validate data. ■ Communicate/document data.
Nursing Diagnosis		
Analyzing and synthesizing data	<p>To identify patient strengths and health problems that can be prevented or resolved by collaborative and nursing interventions.</p> <p>To develop a list of nursing and collaborative problems.</p>	<ul style="list-style-type: none"> ■ Interpret and analyze data: <ul style="list-style-type: none"> — Compare data against standards. — Cluster or group data (generate tentative hypotheses). — Identify gaps and inconsistencies. ■ Determine patient's strengths, risks, diagnoses, and problems. ■ Formulate diagnostic statements. ■ Document priority nursing diagnoses on the nursing plan of care.
Planning		
Determining how to prevent, reduce, or resolve the identified priority patient problems; how to support patient strengths; and how to implement nursing interventions in an organized, individualized, and goal-directed manner	To develop an individualized plan of care that specifies patient goals/desired outcomes, and related priority nursing interventions.	<ul style="list-style-type: none"> ■ Set priorities and goals/outcomes in collaboration with patient. ■ Write goals/desired outcomes. ■ Select nursing strategies/interventions. ■ Consult other health professionals. ■ Write nursing interventions and nursing plan of care. ■ Communicate plan of care to relevant healthcare providers.
Implementation		
Carrying out (or delegating) and then documenting the planned nursing interventions	To assist the patient to meet desired goals/outcomes; promote wellness; prevent illness and disease; restore health; and facilitate coping with altered functioning.	<ul style="list-style-type: none"> ■ Reassess the patient to update the database to keep it current. ■ Determine the nurse's need for assistance. ■ Perform planned priority nursing interventions. ■ Communicate what nursing actions were implemented: <ul style="list-style-type: none"> — Document care and patient responses to care. — Give verbal reports as necessary.
Evaluation		
Measuring the degree to which goals/outcomes have been achieved and identifying factors that positively or negatively influence goal achievement	To determine whether to continue, modify, or terminate the plan of care.	<ul style="list-style-type: none"> ■ Collaborate with patient and collect data related to desired outcomes. ■ Judge whether goals/outcomes have been achieved. ■ Relate nursing actions to patient outcomes. ■ Make decisions about problem status. ■ Review and modify the plan of care as indicated or terminate it. ■ Document achievement of outcomes and modification of the plan of care.

nurse assesses the patient to determine the patient's continued need for the medication, response to the medication, and potential side effects of the medication.

SAFETY ALERT New nurses are often afraid to ask for help as they try to work independently. Undertaking a task better completed by more than one person is dangerous for the nurse and for the patient. Patient safety supersedes the desire to “do it all.” Before undertaking any physical activity involving a patient, assess the safety risk to you and to the patient. Follow hospital guidelines for moving and transferring patients. Use assistive devices if available and ask for help from physical therapists, UAPs, and nursing colleagues. Although family members may be present and willing, they should not take part in transferring and moving patients. Remember, patient safety comes first.

Each phase of the nursing process affects the others. For example, if inadequate data are obtained during assessment, the nursing diagnoses will be incomplete or incorrect; inaccuracy will also be reflected in the planning, implementation, and evaluation phases. Because the nursing process is an organizing tool that guides the nurse's approach to patient care and decision making, the process always begins with accurate data collection.

Assessment

Assessment is the systematic and continuous collection of data about a patient for the purpose of determining the patient's current and ongoing health status, predicting the patient's health risks, and identifying appropriate health-promoting activities. Assessment is a continuous process carried out during all phases of the nursing process. For example, in the evaluation phase, the nurse assesses the outcomes of the nursing interventions and evaluates goal achievement. All phases of the nursing process depend on the accurate and complete collection of assessment data.

A nursing assessment focuses on a patient's responses to a health problem. It includes subjective data obtained from the patient or family about the patient's needs, health condition, health practices, values, health history, and lifestyle. It also includes objective data obtained through assessment and physical examination of the patient. Available sources, including the patient's medical record or office visit records, are used to assist the nurse in developing a database that includes the patient's past medical history and previous current health status (see the module on Assessment for further information).

Assessment data can be organized according to one of several models. Most nursing programs develop their own framework for nursing assessment data based on these models. One example is Gordon's 11 functional health patterns to organize the data (Gordon, 2010):

1. Health perception–health management pattern
2. Nutritional-metabolic pattern
3. Elimination pattern
4. Activity-exercise pattern
5. Sleep-rest pattern
6. Cognitive-perceptual pattern
7. Self-perception/self-concept pattern
8. Role-relationship pattern

9. Sexuality-reproductive pattern
10. Coping/stress-tolerance pattern
11. Value-belief pattern.

Another example is Roy's adaptation model, which states that the goal of nursing is to promote adaptation in each of four adaptive modes:

1. Physiologic
2. Self-concept
3. Role function
4. Interdependence (Roy, 2008).

Roy separates the assessment portion of the nursing process into two phases: assessment of behavior and assessment of stimuli. Behaviors include subjective and objective behaviors (i.e., symptoms and signs, respectively) as well as adaptive and ineffective behaviors (i.e., does the behavior promote health or not). Stimuli include focal, contextual, and residual stimuli. The focal stimulus is what the patient is most focused on and is often the origin of the “related to” phrase of the nursing diagnosis. Contextual stimuli are all the factors that contribute to the patient's interpretation of the focal stimulus, including environment, background, culture, and so on. Residual stimuli are factors that do not have a clear effect on the situation. Once the relationship between the factors is clear, then the stimulus is categorized as a focal or contextual stimulus.

Another common way to organize assessment data is by body systems:

1. Immune system
2. Respiratory system
3. Cardiovascular system
4. Nervous system
5. Musculoskeletal system
6. Gastrointestinal system
7. Genitourinary system
8. Reproductive system.

Figure 36-7 » provides an example of how data might be organized according to a systems assessment or complete assessment (using the Case Study featuring Amanda Aquilini).

After data have been collected, it is validated (see the module on Assessment) and analyzed. Analysis involves three steps:

1. Comparing data against standards (to identify significant cues)
2. Clustering cues (to generate tentative hypotheses)
3. Identifying gaps and inconsistencies.

Experienced nurses perform these activities continuously rather than sequentially as data clusters around current health problems that require interventions. For this reason, nurses should think critically about what to assess.

When gathering and clustering assessment data for children, the nurse will need to include the parents as a major source of subjective data as well as asking the child about his or her feelings. Assessment of the family's needs related to the child's illness (e.g., does lack of insurance present a barrier to accessing services or paying for prescriptions?) is also necessary. See the Lifespan Considerations section for more detail on using the nursing process with children.

NURSING ADMINISTRATION ASSESSMENT

Figure 36-7 ➤ Assessment for Amanda Aquilini. (continued)

Case Study » Part 1

Amanda Aquilini, a 28-year-old married attorney with one child, was admitted to the medical unit of the local hospital with a medical diagnosis of pneumonia throughout her right lung. She has been assigned to Nurse Mary Medina, RN. After Mrs. Aquilini is oriented to her room by the UAP, Nurse Medina does her admission assessment (see **Figure 36-8** »).

During the interview, Nurse Medina learns that Mrs. Aquilini has had a “chest cold” for 2 weeks and has been experiencing shortness of breath when she tries to cook dinner or clean the house. Even putting her child to bed makes her short of breath. Mrs. Aquilini reports that for the past few days, she has not felt like eating very much and is only drinking a couple of glasses of tea every day. She states she has had a productive cough with a medium amount of thick, foul-smelling, pink sputum. Mrs. Aquilini tells Nurse Medina that she hasn’t felt like going to work; she just feels tired all the time. She states she doesn’t smoke and only drinks a glass of wine occasionally. Mrs. Aquilini likes to work out in the yard or go for a walk three or four times a week but lately has not had the energy to do these things. She currently takes levothyroxine 0.1 mg daily, and her last hospitalization was for the delivery of her child 3 years ago. Mrs. Aquilini states she is allergic to penicillin but not to foods, latex, or iodine.

On physical examination, Mrs. Aquilini is 62 in. (157 cm) tall and weighs 125 lbs. (56.7 kg). Vital signs: T_O 103°F (39.4°C); P 92 bpm; R 28/min; blood pressure 122/80 mmHg, and oxygen saturation (O₂ Sat) 95% on room air. Nurse Medina observes that Mrs. Aquilini’s skin is dry, her cheeks are flushed, and she is experiencing chills. Auscultation reveals inspiratory rhonchi with diminished breath sounds in the right lung. Respirations are shallow. Her oral mucous membranes are pale and dry and her skin turgor when tented is >3 seconds. She speaks in short sentences. Peripheral pulses are weak and equal bilateral in all four extremities.

Clinical Reasoning Questions Level I

1. Which assessment data are salient cues?
2. Do these cues form any clusters? What are they?

Clinical Reasoning Questions Level II

3. Are there any other questions you would ask Mrs. Aquilini to further clarify her health status?
4. Which cluster of significant cues would be the priority? Why?

Figure 36-8 » Assessment: Mrs. Aquilini’s admission assessment reveals the following: temperature 103°F (39.4°C); pulse 92 bpm; respirations 28/min; and blood pressure 122/80 mmHg. Nurse Medina observes that Mrs. Aquilini’s skin is dry, her cheeks are flushed, and she is experiencing chills. Auscultation reveals inspiratory crackles with diminished breath sounds in the right lung.

Diagnosis

In the diagnosis phase of the nursing process, nurses use critical thinking skills to cluster the assessment data and identify problems. Diagnosis is a pivotal step in the nursing process. Assessment activities preceding this phase are directed toward formulating a nursing diagnosis, and the care-planning activities following this phase are based on the nursing diagnoses.

Nursing diagnoses are developed and periodically updated by **NANDA-I** (formerly the North American Nursing Diagnosis Association). In 1990, NANDA-I adopted an official working definition of **nursing diagnosis**, “a clinical judgment concerning a human response to health conditions/life processes, or a vulnerability for that response, by an individual, family, group or community. A nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse has accountability” (NANDA-I, 2013). This definition implies the following:

- Registered nurses are responsible for making nursing diagnoses, even though other nursing personnel may contribute data to the process of diagnosing and may implement specified nursing care. In the *Standards of Professional Nursing Practice*, Standard 2 addresses the fact that registered nurses determine the diagnoses or issues from analysis of the assessment data (American Nurses Association, 2010a). The Joint Commission embraces ANA’s *Nursing: Scope and Standards of Practice* and therefore requires evidence of nursing diagnoses in patients’ medical records.
- The domains of nursing diagnoses include only those health states that nurses are educated and licensed to treat within their scope of practice (see the module on Legal Issues for further information). For example, nurses can diagnose and treat *Deficient Knowledge*, *Ineffective Coping*, or *Imbalanced Nutrition*, all of which are the human responses to the medical diagnosis of diabetes mellitus.
- A nursing diagnosis is a judgment made only after thorough, systematic assessment and data collection.
- Nursing diagnoses describe a continuum of health states: deviations from health, presence of risk factors, and areas of enhanced personal growth.

The current organization of nursing diagnoses is called Taxonomy II (NANDA-I, 2014). Taxonomy II has three levels: domains, classes, and nursing diagnoses. The diagnoses are coded according to seven axes that reflect elements of a patient’s response addressed in the diagnosis: diagnostic focus, subject, judgment, location, age, time, and status.

» **Stay Current:** For more information about NANDA-I-approved nursing diagnoses, refer to the NANDA-I website (www.nanda.org) and see Appendix A.

To identify nursing diagnoses effectively and then create and complete a nursing plan of care, the nurse must be familiar with:

- Common terms used with nursing diagnoses
- The difference between a nursing diagnosis and a medical diagnosis

- Types of nursing diagnoses
- Components of a nursing diagnosis.

Common Terms

A diagnosis is a statement or conclusion regarding the nature of a phenomenon. The standardized NANDA-I names for the nursing diagnoses are called **diagnostic labels**. The patient's problem statement is called a nursing diagnosis, and it includes the diagnostic label plus the etiology (causal relationship between a problem and its related or risk factors). **Risk factors** are factors that cause a patient to be vulnerable to developing a health problem. The term *diagnosing* refers to the reasoning process the nurse uses to formulate the nursing diagnosis.

Nursing diagnoses are developed using a multiaxial system. Axes are categories that address components of the diagnostic process. There are seven axes: the focus of the diagnosis, the subject of the diagnosis (patient, family, and so on), nursing judgment (impaired, inefficient, ineffective, and so on), locations (cardiac, pulmonary, leg, and so on), age (child, adult, adolescent, and so on), time (chronic, acute, intermittent, constant, and so on), and status of the diagnosis (problem-focused, risk, or health promotion).

Axis 1, the focus of the diagnosis, is the “principal element or the fundamental and essential part, the root, of the nursing diagnosis” (NANDA-I, 2014, p. 93). In the diagnosis *Compromised Family Coping*, coping is the principal element. Axis 2, the subject, may be explicit or implicit. For example, in the nursing diagnosis *Compromised Family Coping*, the subject, “family,” comes from Axis 2. In the nursing diagnosis, *Ineffective Airway Clearance*, the subject, the patient, is implied. Axis 3 consists of modifiers that give meaning to the focus of the diagnosis. In the diagnosis *Compromised Family Coping*, the judgment is compromised (Axis 3). Other judgments in nursing diagnoses include complicated, decreased, delayed, ineffective, insufficient, and several other modifiers and descriptors.

Axis 4 provides a description, location, system, or function affected by the focus. In some cases, the location may not be a part of the body—for example, bed, wheelchair, or crutches. In the diagnosis *Ineffective Airway Clearance*, “airway” stems from Axis 4: airway is the location of the focus. Axis 5, age, represents the categorical age of the subject based on World Health Organization (WHO) definitions. Ages are categorized as fetus, neonate, infant, child, adolescent, and adult. For example, a nursing diagnosis that categorizes the age of the subject could be *Ineffective Infant Feeding Pattern*. By convention, an older adult is defined as an individual age 65 or older. Older adult is not defined by WHO (NANDA-I, 2014).

Axis 6 describes time as it relates to the nursing diagnosis. Time may be episodic, for example, perioperative, the time before and after surgery; it may be situational and relate to a set of circumstances, for example labor and delivery; or it may be intermittent or periodic. Time can also be acute, lasting less than 3 months, or chronic, lasting more than 3 months. In the diagnosis *Ineffective Coping Related to Chronic Back Pain*, the subject has endured back pain for at least 3 months. Other time-related terms include continuous and intermittent.

Axis 7, the status of a diagnosis, determines an actual or current health problem (a problem-focused diagnosis), a

future problem (a risk diagnosis), or a desire to improve health and well-being (a **health promotion diagnosis**).

Nurses develop diagnoses by determining the focus (Axis 1) and adding a judgment (Axis 3). There are times when Axes 1 and 3 are combined—for example, *Nausea or Fatigue*. After determining the focus and the judgment, the subject is added. However, this is not necessary if the subject is an individual. Additional axes are then used to provide further detail and clarity.

Nursing Diagnosis Versus Medical Diagnosis

A nursing diagnosis is a statement of nursing judgment and refers to a condition that nurses, by virtue of their education, experience, and expertise, are licensed to treat. Nursing diagnoses describe the human response or a patient's physical, sociocultural, psychologic, and spiritual responses to an illness or a health condition. A medical diagnosis is made by a licensed provider such as a physician, advanced practice nurse, or physician assistant. Medical diagnoses refer to disease processes—specific pathophysiologic responses that are fairly uniform from one patient to another. Clinical Example D shows how these responses can vary among individuals:

Clinical Example D

Seventy-year-old Mary Cain and 20-year-old Kristi Vidan both have rheumatoid arthritis. Their disease processes are much the same. X-ray studies show that in both patients, the extent of inflammation and the number of joints involved are similar, and both patients experience almost constant pain. Mrs. Cain views her condition as part of the aging process and is responding with acceptance. Ms. Vidan, however, is responding with anger and hostility because she views her disease as a threat to her personal identity, role performance, and self-esteem.

Critical Thinking Questions

1. What barrier to effective pain management could Ms. Cain's acceptance of her rheumatoid arthritis possibly present?
2. How might the nurse separate the issue of personal identity for Ms. Vidan from her rheumatoid arthritis?
3. What are three issues of role performance that might be foremost in Ms. Vidan's mind when she thinks about her rheumatoid arthritis?
4. What aspects of rheumatoid arthritis mark it as an “old person's disease”?
5. How might the nurse help shift Ms. Vidan's concept of self-esteem from dwelling on her having rheumatoid arthritis to focusing on her effectively managing it?
6. Why might a results-based approach to the problem of rheumatoid arthritis be effective for helping Ms. Vidan manage the disease?

A patient's medical diagnosis remains the same for as long as the disease process is present, but nursing diagnoses change as the patient's responses change. Ms. Vidan's response to her illness may change over time to become more similar to those of Ms. Cain.

Types of Nursing Diagnoses

The current types of nursing diagnoses are problem-focused diagnoses (also referred to as actual diagnoses), risk

diagnoses, health promotion diagnoses, and syndrome diagnoses (NANDA-I, 2014):

1. A **problem-focused diagnosis** is a patient problem that is present at the time of the nursing assessment. Examples are *Ineffective Breathing Pattern*, *Acute Pain*, and *Anxiety*. A problem-focused nursing diagnosis is based on a cluster of associated assessment data.
2. A **risk nursing diagnosis** is a clinical judgment that a problem does not exist, but the presence of risk factors indicates that a problem is likely to develop unless the nurse intervenes. For example, all hospitalized individuals have some possibility of acquiring an infection; however, a patient with diabetes or a compromised immune system is at higher risk than others. Therefore, the nurse would use the *Risk for Infection* nursing diagnosis to describe the patient's health status. The risk diagnosis documents a patient's health status vulnerability for a single diagnosis or his or her risk for a syndrome diagnosis.
3. A **health promotion diagnosis** reflects a patient's readiness to improve an aspect of health. For example, if a patient expresses the desire to improve eating habits, an appropriate diagnosis would be *Readiness for Enhanced Nutrition*. Similarly, if a woman expresses the desire to improve her health in order to prepare for pregnancy, *Readiness for Enhanced Childbearing Process* would be an appropriate health promotion nursing diagnosis. Health promotion diagnoses reflect patient awareness of well-being and the desire to maintain or enhance this state.
4. A **syndrome diagnosis** recognizes a cluster of individual nursing diagnoses that occur simultaneously and may result in the best patient outcomes if addressed concurrently (NANDA-I, 2016). Syndrome diagnoses may be problem-focused or risk diagnoses. For example, *Risk for Disuse Syndrome* may be assigned to patients who are bedridden. The cluster of diagnoses associated with disuse syndrome include *Impaired Physical Mobility*, *Risk for Impaired Tissue Integrity*, *Risk for Activity Intolerance*, *Risk for Constipation*, *Risk for Infection*, *Risk for Injury*, *Risk for Powerlessness*, and *Impaired Gas Exchange*.

Components of a Nursing Diagnosis

A nursing diagnosis has three components, and each component serves a specific purpose:

1. The **diagnostic label** ("What is the focus or subject of the problem?")
2. The **etiology** ("Where did it come from?" "What is it related to?")
3. The **defining characteristics** ("What does it look like?").

The Diagnostic Label

A NANDA-I diagnostic label describes the patient's response to a health problem for which nursing care is given. The diagnostic label describes the patient's health status clearly and concisely in a few words such as *Infection*, *Nausea*, or *Urinary Incontinence*. The diagnostic label identifies the topic that directs the formation of a patient goal

and desired outcomes. It may also suggest some nursing interventions.

To be clinically useful, diagnostic labels need to be specific; when the word *specify* follows the label, the nurse states the area in which the problem occurs. The only nursing diagnosis in the 2015–2017 list of NANDA-I diagnoses that requires specification is *Decisional Conflict*. For example, a family that is trying to decide whether to remove a feeding tube for an elderly parent at the end of life may receive the nursing diagnosis *Decisional Conflict* (removing feeding tube).

Modifiers, Axis 3, reflect nursing judgment, intensify the focus of the diagnosis, and give it specific meaning. For example, commonly used modifiers include

- **Deficient:** inadequate in amount, quality, or degree; not sufficient; incomplete
- **Impaired:** made worse, weakened, damaged, reduced, deteriorated
- **Decreased:** lesser in size, amount, or degree
- **Ineffective:** not producing the desired effect
- **Compromised:** to make vulnerable to threat.

Each diagnostic label approved by NANDA-I carries a definition that clarifies its meaning. For example, the definition of the diagnostic label *Activity Intolerance* is given in **Table 36–6** >>.

The Etiology (Related Factors and Risk Factors)

The etiology component of a nursing diagnosis identifies one or more probable causes of the health problem, thereby giving a direction to the required nursing care and enabling the nurse to individualize the patient's care. Table 36–6 demonstrates the probable causes of *Activity Intolerance* that may include sedentary lifestyle, generalized weakness, and other factors. Differentiating among probable causes in the nursing diagnosis is essential because the cause of each problem may require different nursing interventions. **Table 36–7** >> provides an example of patients with the nursing diagnosis of *Constipation* who have different etiologies; therefore, they require different interventions.

TABLE 36–6 Example of the Components of a Nursing Diagnosis

Diagnostic Label and Definition	Related Factors	Defining Characteristics
<i>Activity Intolerance:</i> Insufficient physiologic or psychologic energy to endure or complete required or desired daily activities	Bedrest or immobility Generalized weakness Imbalance between oxygen supply/demand Sedentary lifestyle	Verbal report of fatigue or weakness Abnormal heart rate or blood pressure response to activity Electrocardiographic changes reflecting arrhythmias or ischemia Exertional discomfort or dyspnea

Source: From NANDA-I. (2014). *NANDA nursing diagnoses: Definitions and classification 2015–2017*. Chichester, UK: Wiley-Blackwell. Adapted with permission.

TABLE 36–7 Example of a Nursing Diagnosis with Different Etiologies

Diagnostic Label (Problem)	Patient	Etiology
Constipation	Al Martinez	Long-term laxative use
	Jerry Wong	Inactivity and insufficient fluid intake
	Tanya Brown	Depression
	Caitlin Shea	Change in eating pattern

The Defining Characteristics

Defining characteristics refer to the cluster of signs and symptoms that indicate the presence of a particular diagnostic label. For actual nursing diagnoses, the defining characteristics are the patient's signs and symptoms. For risk nursing diagnoses, subjective and objective signs are not present. Thus, the factors that cause the patient to be more vulnerable to the problem are the etiology of a risk nursing diagnosis. Characteristics can be listed separately according to whether they are subjective or objective in nature. For example, the problem-focused diagnostic label *Fear* includes the following defining characteristics:

- Report of apprehension, being scared, having increased tension
- Diminished learning ability, unable to solve problems
- Diarrhea, vomiting, dry mouth, increase in pulse rate.

The risk diagnostic label *Risk for Falls* includes the following defining characteristics:

- Having a history of falling, using a cane to walk
- Lack of gate on the stairs, lack of parental supervision
- Tranquilizer use, anemia, visual difficulties.

Developing a Nursing Diagnosis

The skills and abilities of critical thinking discussed at the beginning of this module are used by nurses to analyze and

apply reasoning to formulate nursing diagnoses. Data can be compared to standards, which are accepted measures, rules, or norms. For example, growth and development charts, normal ranges for laboratory values, or acceptable ranges for vital signs can provide standards against which to compare patient data when looking for norms. See **Table 36–8** » for some examples of how patient cues can compare with standards/norms.

An experienced nurse may enter a patient's room and immediately observe significant data and draw conclusions about the patient. As a result of attaining knowledge, skill, and expertise in the practice setting, the expert nurse may seem to perform these mental processes automatically. Novice nurses, however, need guidelines to understand and formulate nursing diagnoses (see the Critical Thinking section at the beginning of this module for further information).

Skillful assessment minimizes gaps and inconsistencies in data collection; however, data analysis should include a final check to ensure that assessment data are complete and current. Do the data make sense? For example, a nurse may learn from the nursing history that the patient reports not having seen a physician in 15 years, yet during the physical health examination he states, "My doctor takes my blood pressure every year." All inconsistencies must be clarified before a valid pattern can be established. See **Table 36–9** » for some examples of formulating nursing diagnoses based on patient cues.

After grouping and clustering the data, the nurse and patient together identify problems that support problem-focused and risk diagnoses, and if appropriate, health promotion diagnoses. This is primarily a decision-making process. In addition, the nurse determines whether the patient's problem is a nursing diagnosis, medical diagnosis, or collaborative problem. **Figure 36–9** » is a decision tree diagram that can help nurses make decisions about what kind of diagnosis is appropriate.

At this stage, the nurse and patient also establish the patient's strengths, resources, and abilities to cope. Most individuals have a clearer perception of their problems or weaknesses than of their strengths and assets, which they often take for granted. By taking an inventory of strengths,

TABLE 36–8 Examples of Patient Cues Compared to Standards/Norms

Cues from Patient	Standard/Norm	Interpretation of Cues
Height is 5 ft., 2 in. Woman with small frame Weighs 240 lb	Height and weight tables indicate that the "ideal" weight for a woman 5 ft., 2 in. with a small frame is 108–121 lb.	Deviation from population norms
Child is 17 months old. Parents state child has not yet attempted to speak. Child laughs aloud and makes cooing sounds.	Children usually speak their first word by 10–12 months of age.	Developmental delay
States, "I'm just not hungry these days." Ate only 15% of food on breakfast tray. Has lost 30 lb in past 3 months.	Patient usually eats three balanced meals per day. Adults typically maintain stable weight.	Changes in patient's usual health status
Mrs. Stuart reports that lately her husband angers easily. "Yesterday he even yelled at the dog." "He just seems so tense."	Mr. Stuart is usually relaxed and easygoing. He is friendly and kind to animals.	Changes in patient's usual behavior

TABLE 36–9 Examples of Formulating Nursing Diagnoses from Patient Cues

Patient Cue Clusters	Tentative Identification of Problems	Formulated Diagnostic Statements
“No appetite” since congestion Has not eaten today Last fluids at noon today Nauseated ×2 days	<i>Imbalanced Nutrition: Less Than Body Requirements</i>	<i>Imbalanced Nutrition: Less Than Body Requirements</i> related to decreased appetite and nausea (secondary to disease process)
Last fluids at noon today Oral temp 39.4°C (103°F) Skin hot and pale, cheeks flushed Mucous membranes dry Poor skin turgor Decreased urinary frequency and amount ×2 days	<i>Deficient Fluid Volume</i>	<i>Deficient Fluid Volume</i> related to intake insufficient to replace fluid loss secondary to fever, diaphoresis, anorexia
Difficulty sleeping because of cough “Can’t breathe lying down”	<i>Disturbed Sleep Pattern</i>	<i>Disturbed Sleep Pattern</i> related to cough, pain, orthopnea, fever, and diaphoresis
States, “I feel weak” Short of breath on exertion <i>Cues from cognitive/perceptual pattern:</i> Responsive but fatigued “I can think OK, just weak.” <i>Cues from cardiovascular pattern:</i> Radial pulses weak, regular; pulse rate 92 bpm	<i>Activity Intolerance</i>	<i>Activity Intolerance</i> related to general weakness, imbalance between oxygen supply/demand
Husband out of town; will be back tomorrow afternoon Child with neighbor until husband returns	<i>Interrupted Family Processes</i> related to mother’s illness and temporary unavailability of father to provide child care	<i>Interrupted Family Processes</i> related to mother’s illness and temporary unavailability of father to provide child care
Skin hot, pale, and moist Respirations shallow; chest expansion slight Cough productive of small amounts of thick pale pink sputum Inspiratory crackles auscultated throughout right upper and lower lungs Diminished breath sounds on right side	<i>Ineffective Airway Clearance</i> related to disease process	<i>Ineffective Airway Clearance</i> related to viscous secretions and shallow chest expansion secondary to pain, fluid volume deficit, and fatigue

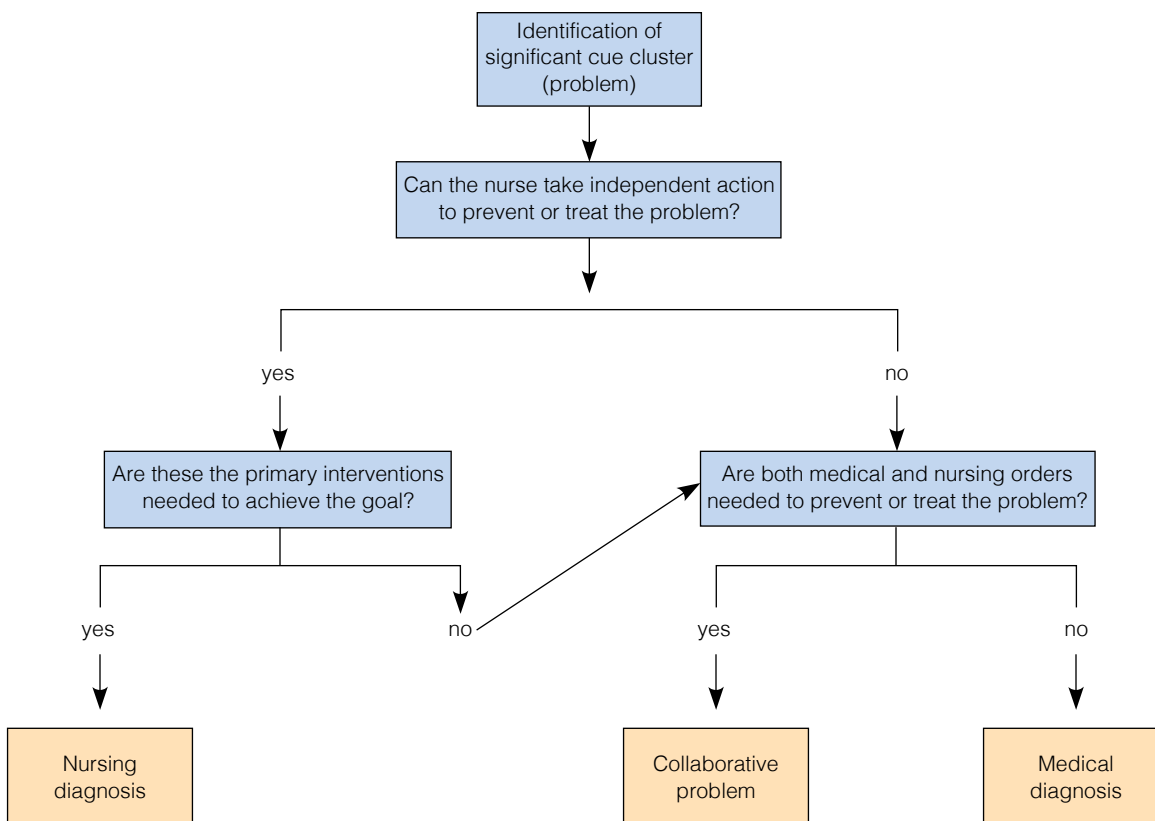

**Figure 36–9** » Decision tree for differentiating among nursing diagnoses, collaborative problems, and medical diagnoses.

TABLE 36–10 Examples of Two-Part Nursing Diagnosis Statements

Problem	Related to	Etiology
<i>Constipation</i>	related to	prolonged laxative use
<i>Anxiety</i>	related to	threat to physiologic integrity: possible cancer diagnosis

the patient can develop a more well-rounded self-concept and self-image. Strengths can be an aid to mobilizing health and regenerative processes. A patient's strength might include weight that is within the normal range for age and height, a strength that may enable the patient to recuperate from surgery faster and with fewer complications. Another patient's strength might be the absence of allergies or a non-smoking history.

A patient's strengths can be found in the nursing assessment record (health, home life, education, recreation, exercise, work, family and friends, religious beliefs, and sense of humor, for example), the health examination, and the patient's records.

Writing a Nursing Diagnosis Statement

Most nursing diagnoses are written as two-part or three-part statements.

Basic Two-Part Statement

The basic two-part statement includes the following:

1. **Problem (P):** NANDA-I label ("What's the problem?")
2. **Etiology (E):** related to . . . ("What's causing the problem?")

The two parts are joined by the words *related to* merely to imply a relationship. Some examples of two-part nursing diagnoses are shown in **Table 36–10** >>.

Basic Three-Part Statement

The basic three-part nursing diagnosis statement is called the PES format and includes the following:

1. **Problem (P):** NANDA-I label ("What's the problem?")
2. **Etiology (E):** related to . . . ("What's causing the problem?")
3. **Signs and symptoms (S):** defining characteristics of problem ("What's it look like?")

Actual nursing diagnoses can be documented by using a three-part statement (see **Table 36–11** >>) because the signs and symptoms have been identified. This format cannot be used for risk diagnoses because the patient does not have signs and symptoms of the diagnosis. The PES format is especially recommended for beginner nurses

because the signs and symptoms validate why the diagnosis was chosen and make the problem statement more descriptive.

Basic One-Part Statement

Some diagnostic statements, such as health promotion diagnoses and syndrome nursing diagnoses, consist of a NANDA-I label only. As the diagnostic labels are refined, they tend to become more specific so that nursing interventions can be derived from the label itself. Therefore, an etiology may not be needed. For example, adding an etiology to the label *Rape-Trauma Syndrome* does not make the label any more descriptive or useful.

NANDA-I has specified that any new health promotion diagnoses will be developed as one-part statements beginning with the words *Readiness for Enhanced* followed by the desired higher level of wellness (for example, *Readiness for Enhanced Parenting*). Currently, the NANDA-I list includes several health promotion diagnoses. Some of these are *Spiritual Well-Being*, *Breastfeeding*, *Coping*, and *Sleep*. These are usually accepted as one-part statements but may be made more explicit by adding a descriptor, for example, *Readiness for Enhanced Communication* (English-speaking class). See **Table 36–12** >> for general guidelines for writing all of the nursing diagnostic statements.

Common Variations

Common variations of the basic one-, two-, and three-part statements include the following:

1. Writing *unknown etiology* when the defining characteristics are present but the nurse does not know the cause or contributing factors. An example is *Acute Confusion* related to unknown etiology.
2. Using the phrase *complex factors* when there are too many etiologic factors or when they are too complex to state in a brief phrase. The actual causes of chronic low self-esteem, for instance, may be long term and complex, as in the following nursing diagnosis: *Chronic Low Self-Esteem* related to complex factors.
3. Using *secondary to* divides the etiology into two parts, thereby making the statement more descriptive and useful. The part following *secondary to* is often a pathophysiologic or disease process or a medical diagnosis, as in *Risk for Impaired Skin Integrity* related to decreased peripheral circulation secondary to diabetes.
4. Adding a second part to the general response or NANDA-I label to make it more precise. For example, the diagnosis *Impaired Skin Integrity* does not indicate the location of the problem. To make this label more specific, the nurse can add a descriptor as follows: *Impaired Skin Integrity* (left lateral ankle) related to decreased peripheral circulation.

TABLE 36–11 Example of a Three-Part Nursing Diagnosis Statement

Problem	Related to	Etiology	As Manifested by	Signs and Symptoms
<i>Situational Low Self-Esteem</i>	related to (r/t)	feelings of rejection by husband	as manifested by (amb)	hypersensitivity to criticism; states, "I don't know if I can manage by myself," and rejects positive feedback

TABLE 36–12 Guidelines for Writing a Nursing Diagnostic Statement

Guideline	Correct Statement	Incorrect or Ambiguous Statement
1. State in terms of a problem, not a need.	<i>Deficient Fluid Volume</i> (problem) related to fever	Fluid Replacement (need) related to fever
2. Word the statement so that it is legally advisable.	<i>Impaired Skin Integrity</i> related to immobility (legally acceptable)	<i>Impaired Skin Integrity</i> related to improper positioning (implies legal liability)
3. Use nonjudgmental statements.	<i>Spiritual Distress</i> related to inability to attend church services secondary to immobility (nonjudgmental)	<i>Spiritual Distress</i> related to strict rules necessitating church attendance (judgmental)
4. Make sure that both elements of the statement do not say the same thing.	<i>Risk for Impaired Skin Integrity</i> related to immobility	<i>Impaired Skin Integrity</i> related to ulceration of sacral area (response and probable cause are the same)
5. Be sure that cause and effect are correctly stated (i.e., the etiology causes the problem or puts the patient at risk for the problem).	<i>Acute Pain</i> : Severe headache related to fear of addiction to narcotics	<i>Acute Pain</i> related to severe headache
6. Word the diagnosis specifically and precisely to provide direction for planning nursing interventions.	<i>Impaired Oral Mucous Membrane</i> related to decreased salivation secondary to radiation of neck (specific)	<i>Impaired Oral Mucous Membrane</i> related to noxious agent (vague)
7. Use nursing terminology rather than medical terminology to describe the patient's response.	<i>Ineffective Airway Clearance</i> related to accumulation of secretions in lungs (nursing terminology)	<i>Risk for Pneumonia</i> (medical terminology)
8. Use nursing terminology rather than medical terminology to describe the probable cause of the patient's response.	<i>Ineffective Airway Clearance</i> related to accumulation of secretions in lungs (nursing terminology)	<i>Ineffective Airway Clearance</i> related to emphysema (medical terminology)

Avoiding Errors in Diagnostic Statements

It is important that nurses make nursing diagnoses with a high level of accuracy. Nurses can avoid some common errors of reasoning by recognizing them and applying appropriate critical thinking skills. Errors can occur at any point in the diagnostic process: data collection, data interpretation, and data clustering. Nurses can do the following to minimize diagnostic errors:

- **Verify.** Hypothesize possible explanations of the data, but realize that all diagnoses are only tentative until they are verified. Begin and end the diagnostic process by talking with the patient and family. When collecting health data, ask patients to describe both the problem and the factors they believe to be the cause of the problem. At the end of the process, ask patients to confirm the accuracy and relevance of the nursing diagnoses.
- **Build a good knowledge base and acquire clinical experience.** Nurses must apply knowledge from many different areas to recognize significant cues and patterns and generate hypotheses about the assessment data. Principles from chemistry, anatomy, and pharmacology, psychology, and sociology, among other disciplines, help the nurse understand patient data in a different way.
- **Have a working knowledge of what is normal.** Nurses need to know the population norms for vital signs, laboratory tests, speech development, breath sounds, and other indicators. In addition, nurses must determine what is usual for a particular patient, taking into account age, physical makeup, lifestyle, culture, and the patient's own perception of her normal status. For example, the generally accepted normal blood pressure for adults is in the range of 110/60 to 140/80 mmHg. However, a nurse might obtain a reading of 90/50 that is normal for a

particular patient. The nurse should compare actual findings to the patient's baseline when possible.

- **Consult resources.** Both novices and experienced nurses should consult appropriate resources whenever in doubt about a diagnosis. Professional literature, nursing colleagues, and other professionals are appropriate resources. The nurse should use a nursing diagnosis handbook to determine whether the patient's signs and symptoms truly fit the definition of the NANDA-I label chosen.
- **Base diagnoses on patterns—that is, on behavior over time—rather than on an isolated incident.** For example, even though the patient is concerned today about needing to leave her child with a neighbor, it is likely that this concern will be resolved without intervention by the next day. Therefore, the nurse should not diagnose *Interrupted Family Processes*.
- **Improve critical thinking skills.** Critical thinking skills help nurses increase awareness of patients' problems and also help nurses avoid errors in thinking, such as overgeneralizing, stereotyping, and making unwarranted assumptions about patients.

Case Study » Part 2

Nurse Medina wants to use the assessment data she obtained during the admission assessment of Mrs. Aquilini to identify the priority nursing diagnosis. First, she makes a list of all of the assessment data and then separates the significant cues that form clusters. Some of the significant cues came from Mrs. Aquilini's recent history at home, but others came from physical findings Nurse Medina obtained:

- "Chest cold" for 2 weeks
- Shortness of breath with activity
- Lung sounds—inspiratory crackles with diminished breath sounds in right lung

Figure 36-10 >> **Diagnosis:** After analysis, Nurse Medina formulates a nursing diagnosis: *Ineffective Airway Clearance* related to accumulated mucus obstructing airways (secondary to pneumonia).

- Drinking fluids less
- Feels tired all the time; no energy to do home activities or go to work
- Does not smoke
- T_O 103°F (34.4°C), P 92 bpm, R 28/min, BP 122/80 mmHg, and O₂ Sat 95% on room air
- Productive cough with thick, foul-smelling green sputum
- Speaks in short sentences.

Based on the above assessment cluster and the fact that Mrs. Aquilini has a medical diagnosis of pneumonia, Nurse Medina feels confident that the priority nursing diagnosis would involve Mrs. Aquilini's response to the infection in her right lung. There are many NANDA-I nursing diagnoses related to the respiratory system. Nurse Medina decides the definition of the *Ineffective Airway Clearance* nursing diagnosis best fits Mrs. Aquilini's signs and symptoms. So the diagnostic statement for the top priority nursing diagnosis for Mrs. Aquilini is *Ineffective Airway Clearance* related to accumulated mucus obstructing airways (secondary to pneumonia) (**Figure 36-10** >>>).

Clinical Reasoning Questions Level I

1. How do the assessment data support the nursing diagnosis made by Nurse Medina?
2. Can you identify the different components in this two-part diagnostic statement?

Clinical Reasoning Questions Level II

3. What might be the second and third priority nursing diagnoses for this patient?
4. What other assessment data could you hypothesize might be a potential problem for Mrs. Aquilini because of her medical diagnosis of pneumonia?

Planning

The **planning** phase is a deliberate, systematic phase of the nursing process during which the nurse refers to the patient's assessment data and nursing diagnoses for direction in formulating patient goals. Goals are different from outcomes, although many times these words are used to mean the same thing; the difference is outlined in **Box 36-2** >>>.

Box 36-2

The Difference Between a Goal and an Outcome

Goals are observable patient responses; what the nurse hopes to achieve through nursing actions. Goals are developed in the planning phase of the nursing process. They are broad statements about something the patient strives to achieve and indicate progress toward desired patient behaviors or actions. Goals are what nurses and patients want to happen. They are individualized and specific for each patient. Goals are the responses to nursing interventions.

Outcomes are used to evaluate the patient's response to the plan of care. Desired outcomes are specific, observable criteria used to evaluate whether goals have been met. Desired outcomes are identified during the planning phase: during the evaluation phase, the nurse determines if outcomes have or have not been met. Outcomes are the end results of nursing actions—both desirable and undesirable. Outcomes indicate the effectiveness of nursing actions. The Nursing Outcomes Classification (NOC) identifies 490 standardized and classified patient outcomes that can be used to describe patient status in response to nursing actions (University of Iowa, College of Nursing, 2013). For example:

Nursing diagnosis: *Ineffective Airway Clearance* related to poor cough effort

Goal: Patient will demonstrate an effective cough by 1400 this afternoon.

Desired outcome: Patient maintains a clear airway during the postoperative period.

The terms *goal* and *desired outcome* are often used interchangeably. Sometimes the word "or" is used between them, "goals or outcomes," and sometimes they are written "goals/outcomes." In this text, goals are developed in the planning phase of the nursing process and desired outcomes are used to evaluate the patient's response to the plan of care.

The goals become the basis for the nursing interventions that are developed to prevent, reduce, eliminate, or improve the nursing diagnosis situation. For the plan to be effective, it is important for the patient and support persons (if applicable) to participate in the development of the plan: Nurses do not plan for the patient, but encourage the patient to participate actively to the extent possible. In a home setting, the patient's family members and caregivers are the ones who implement the plan of care; thus, its effectiveness depends largely on them.

When the nurse and patient identify a goal for every nursing diagnosis together, it helps support the nurse-patient relationship. This partnership achieves these other purposes as well:

1. Provides direction for selecting nursing interventions. Ideas for interventions come more easily if the goal clearly and specifically states what the patient is to achieve.
2. Serves as criteria for evaluating patient progress. Although developed in the planning phase of the nursing process, goals serve as the criteria for determining

the effectiveness of nursing interventions and patient progress for desired outcomes in the evaluation phase.

3. Enables closure of the nursing diagnosis situation when the patient and nurse determine the goal has been achieved.
4. Helps motivate the patient and nurse by providing a sense of achievement. As goals are met, both patient and nurse can see that their efforts have been worthwhile. This provides motivation to continue following the plan, especially when difficult lifestyle changes need to be made by the patient.
5. Supports a therapeutic nurse–patient relationship. Any time the nurse and patient are able to move forward together in the patient’s plan of care, the patient gains trust in the nurse, further increasing the likelihood of the plan’s success.

Long-Term and Short-Term Goals

Goals are customized to individual patients, which means they take varying amounts of time to achieve. Because of differences in time, goals are categorized as either short term or long term, depending on the time frames necessary to achieve them.

Short-term goals are useful for patients who require health-care for a short time. In an acute care setting, much of the nurse’s time is spent on the patient’s immediate needs, so most goals are short term and can be achieved by the patient in a range of a few hours to a few days. Examples of short-term goals are:

- Patient will raise her right arm to shoulder height 4 days from today, January 23.
- Patient will identify five salty foods to avoid while on a salt-free diet by tomorrow, May 7.
- Patient will demonstrate how to change his leg dressing before discharge.
- Patient will use a cane to walk 20 feet down the hallway by April 22.

Long-term goals are often used for patients who live at home and have chronic health problems and for patients in nursing homes, extended care facilities, and rehabilitation centers. However, patients in acute care settings also need long-term goals to guide planning for their discharge to long-term care agencies or home care, especially in a managed-care environment. Long-term goals can be achieved by the patient in a range of 1 week to several months. Examples of long-term goals are:

- Patient will regain full use of her right arm 6 weeks from today, June 6.
- Patient will be able to discuss five effective coping strategies for dealing with stressful situations that he has used over a 6-month period of time from today, September 25.
- Patient will eat at least 60% of all meals by the end of 3 weeks from today, June 1.
- Patient will participate in two weekly group activities by sitting quietly and listening attentively by 3 months from today, May 13.

Developing a Goal

Goals are derived from the patient’s nursing diagnoses—primarily from the diagnostic label. Each nursing diagnosis has one goal for the patient to achieve. When developing goals, the nurse should ask the following questions:

1. What about the nursing diagnosis needs to be changed for or by the patient?
2. Is there a healthy response to correct a problem stated in the nursing diagnosis that the patient can achieve as a goal?
3. How will the patient look or behave if the healthy response as a goal is achieved? (What will be seen, heard, measured, palpated, smelled, or otherwise observed through the senses?)
4. What action must the patient do and how well must the patient do it to demonstrate problem resolution or achievement of the goal?

For example, the nursing diagnosis is:

Deficient Fluid Volume related to diarrhea and inadequate intake secondary to nausea

The <i>diagnostic label</i> is “ <i>Deficient Fluid Volume</i> .”	This is the problem.
<i>Related to</i> is “diarrhea and inadequate intake.”	This is the source of the problem.
<i>Secondary to</i> “nausea”	This is the origin of the “related to” factors.

The goal for this nursing diagnosis might be “Patient’s intake and output of fluids will be balanced during his hospitalization.” The patient’s goal reflects maintaining a fluid balance during the time interval he is losing fluids through diarrhea. The goal of fluid balance is the opposite of the nursing diagnostic label *Deficient Fluid Volume*.

Writing a Goal

Goals have specific characteristics that should be included when writing them to fulfill their purpose in the planning phase of the nursing process. Setting a goal helps to identify desired change in a patient’s situation and define the focus of nursing interventions. Common characteristics of goals include being:

- Patient centered (not about nurse activities)
- Specific and concise single actions
- A single goal for each nursing diagnosis
- Directional for nursing interventions
- Measurable
- Quantifiable
- Attainable for an individual patient
- Realistic to an individual patient
- Relevant to an individual patient
- Time limited.

All goals are patient centered in that the patient is always the subject, as indicated by beginning the goal with the words “The patient will” much of the time. Sometimes these

three words are omitted in goals because it is assumed that the subject is the patient unless indicated otherwise. A quick and user-friendly format to follow to write a goal statement is the acronym **SMART** (College of Nurses of Ontario, 2014), which stands for:

- S**pecific single action
- M**easurable
- A**ttainable (achievable)
- R**elevant
- T**ime limited.

Specific Single Action

The goal includes a clearly stated, single action for the patient to do that can be observed directly or indirectly. Any additional information defining how the action is to be done is included in this part of the statement. These are sometimes called *qualifiers* of the action. Information provided about the action is detailed so that other nurses following the nursing plan of care will be able to understand what the patient is to achieve to reach the goal.

Here are some examples of specific single actions for goals. The patient will:

- Walk 20 feet down the hall using a walker.
- Demonstrate giving herself an insulin injection using aseptic technique.
- Identify six foods to avoid that are high in salt content.
- State the purpose of his new medication, nitroglycerin, and when and how to take it.

Measurable

The goal includes a specific, measurable observation or result that is quantifiable. Any nurse observing the patient attempting the single action of the goal will be able to recognize when the patient reaches the goal. In the following examples, the first column does not provide specific measurements or quantities that all nurses would define the same, whereas the second column does. The patient will:

Poorly Written Quantified Measure	Correctly Written Quantified Measure
Go for a walk (need to know distance for goal to be reached).	Walk 20 feet down the hall using a walker.
Understand how to give insulin (understanding doesn't mean being able to do it).	Demonstrate giving herself an insulin injection using aseptic technique.
State foods not to eat (quantify how many and what kind so the understanding is consistent).	Identify six foods to avoid that are high in salt content.
Know about nitroglycerin (need to be specific about what to know).	State the purpose of his new medication, nitroglycerin, and when and how to take it.

Nurses must be aware that some phrases can lead to disagreements about whether the outcome was met. Avoid statements that start with *enable*, *facilitate*, *allow*, *let*, *permit*, or similar verbs followed by the word *patient*. These verbs indicate what the nurse hopes to accomplish, not what the patient will do.

Attainable (Achievable)

The goal is appropriate for the individual patient. The single action to be measured is realistic and one that the patient can complete based on the patient's physical, emotional, and psychologic capabilities and limitations (e.g., finances, equipment, family support, and social services). For example:

- Walking a mile would not be achievable for an end-stage COPD patient (20 feet might be more realistic).
- A 2-year-old would not be able to give her own insulin.
- A 24-year-old could identify foods high in salt content.
- A 68-year-old could discuss nitroglycerin.

Relevant

The goal is applicable to the individual patient. The attainable single action to be measured has a purpose that has been customized for the patient based on the needs of the patient. For example, typically:

- A patient on bedrest would not need a goal about walking.
- A nondiabetic patient does not need to know about insulin injections.
- An ordinary teenager does not need to watch his salt intake.
- A 22-year-old patient without angina does not need to know about nitroglycerin.

Time Limited

The goal has a specific time frame and deadline for the goal to be achieved. During this time period, the nurse evaluates the patient's progress in achieving the goal. **Evaluation** is a planned activity in which patients and healthcare professionals examine the patient's progress. Evaluation may serve as motivation for the patient to continue working to achieve the goal. The time frame is specific to date and hours, days, weeks, or months. For example:

- 3/2 at 0800
- In two months, starting 6/2
- Four hours from 1330
- 6/24 in the morning.

Putting all the SMART components together in the examples above results in the following appropriate goals:

- The patient will walk 20 feet down the hall using a walker by 3/3 at 0800.
- The patient will demonstrate giving herself an insulin injection using aseptic technique by discharge.
- The patient will identify six foods to avoid that are high in salt content in 4 hours from 1330.
- The patient will state the purpose of his new medication, nitroglycerin, and when and how to take it by discharge.

See **Table 36-13** » for examples of goals written in SMART format.

TABLE 36–13 SMART Format

Specific, Single Action	Measurable (Quantifiable, Determines How Often)	Appropriate for Patient	Realistic and Attainable for Patient	Time Frame for Patient to Reach Goal
Patient will drink	2500 mL of fluids daily	Ask yourself "Is this goal appropriate for this specific patient?"	Ask yourself "Is this goal realistic and attainable for this specific patient?"	by _____ time, date
Patient will administer	correct insulin dose using aseptic technique			by day of discharge
Patient will list	three hazards of smoking			by _____ time, date
Patient will walk	30 feet down the hall with his cane			by day of discharge
Patient's right ankle will measure	less than 10 inches in circumference			in 48 hours from _____ time, date
Patient will identify	five foods that are allowed on a low-salt diet			by _____ time, date

The nurse writes the goal statement in the format of subject, verb, goal and time limit. The *subject* in the goal statement is the patient. The *verb* is the specific action the patient is to perform that can be observed. The goal is the patient and nurse’s intended achievement, and the time limit determines by when the goal should be accomplished. Examples of action verbs include:

- | | | |
|---------------|---------|-----------|
| Apply | Discuss | Select |
| Change | Drink | Sit |
| Demonstrate | Explain | State |
| Describe | Inject | Verbalize |
| Differentiate | Prepare | Walk |

Make sure the patient considers the goals important and valuable. Patients are motivated if goals are associated with personal meaning. The nurse should assess the patient’s motivation to achieve goals or make behavioral changes. Some patients may know what they wish to accomplish with regard to their health problem; others may not be aware of their possible health goals. The nurse must actively listen to the patient to determine the patient’s personal values and goals in relation to their current health concerns. Patients are usually motivated and expend the necessary energy to reach goals they consider important.

Case Study » Part 3

Nurse Medina has formulated this diagnostic statement to be the top priority for Mrs. Aquilini based on the assessment cluster of significant cues: *Ineffective Airway Clearance* related to accumulated mucus obstructing airways (secondary to pneumonia). She is now ready to collaborate with Mrs. Aquilini to establish a goal. The following reasoning is part of this discussion:

- Mrs. Aquilini hasn’t been drinking much lately, so her mucus is thick and hard to expel.
- She has inspiratory rhonchi with diminished breath sounds in the right lung, which indicate partial obstructions from the thickened mucus in her airways.
- Because Mrs. Aquilini has increased mucus production from the infection in her lungs, she is experiencing impairment in gas exchange, which results in her intolerance to activities and shortness of breath.

- Because she is breathing faster, she is using more energy to breathe.
- Mrs. Aquilini is experiencing general fatigue as her body fights the lung infection.

Nurse Medina helps Mrs. Aquilini understand that many of her problems are a result of the amount and type of mucus in her airways from the lung infection. Nurse Medina further explains the importance of liquefying the mucus so Mrs. Aquilini can cough more effectively and help clear her airways. Together they decide on a goal: “The patient will drink 3000 mL of fluids daily by 8/12.” Both are satisfied that Mrs. Aquilini can reach this goal within the time frame. Now that the goal has been identified, they begin thinking about interventions that can help Mrs. Aquilini reach her goal (Figure 36–11 »).

Clinical Reasoning Questions Level I

1. What role did the critical thinking skill of reasoning play in the discussion between Nurse Medina and Mrs. Aquilini?
2. Can you identify the different components of the SMART format in the goal they created together?

Figure 36–11 » Planning: Nurse Medina and Mrs. Aquilini collaborate to establish goals (e.g., restore effective breathing pattern and lung ventilation); set outcome criteria (e.g., have a symmetrical respiratory excursion of at least 4 cm); and develop a care plan that includes, but is not limited to, coughing and deep breathing exercises q3h, fluid intake of 3000 mL daily, and daily postural drainage.

Clinical Reasoning Questions Level II

3. Why does Nurse Medina include Mrs. Aquilini in deciding what the goal will be instead of just letting her know she needs to drink more every day?
4. If Mrs. Aquilini did not feel she could drink 3000 mL of fluids daily, what other goal would you suggest based on the information provided in the case study?

Implementation

Implementation is the action phase of the nursing process. In this phase, nurses take all the data acquired in the first three phases of the nursing process and determine interventions that would be most appropriate to help the patient reach the goal stated in the planning phase. Interventions provide data that will be used during the evaluation phase to determine patient outcomes. Implementation is a two-step process. The first step is identifying the best priority interventions for an individual patient, and the second step is the implementation of these interventions.

Nursing Interventions

Interventions include nursing actions, delegation of tasks, and documentation completed to help the patient achieve his or her goal based on the nursing diagnosis. These actions are listed in priority order (see Exemplar 36.C on Prioritizing Care within this module for further information). Nursing interventions focus on:

- Assessing to observe for changes in the patient's status
- Preventing complications
- Reducing risk factors
- Treating through teaching and providing physical care
- Improving health through health promotion and achieving higher levels of wellness.

Correct identification of the etiology during the assessment and nursing diagnosis phases provides the framework for choosing successful nursing interventions. For example, the diagnostic label *Activity Intolerance* may have several etiologies: pain, weakness, sedentary lifestyle, anxiety, or cardiac arrhythmias. Interventions will vary according to the cause of the problem. Sometimes nursing actions treat the patient's response to a disease, illness, or medical condition. Interventions for risk nursing diagnoses focus on measures

to reduce the patient's risk factors found in the etiology of the risk nursing diagnosis. **Table 36-14** » shows examples of typical nursing interventions based on the nursing diagnosis and its etiology.

Types of Nursing Interventions

Nursing interventions include both direct and indirect care. Direct care is an intervention performed through interaction with the patient. Indirect care is an intervention performed away from, but on behalf of, the patient. Attending an interprofessional meeting and managing the care environment are two examples of indirect care. A taxonomy of nursing interventions referred to as the Nursing Interventions Classification (NIC) Taxonomy, developed by the Iowa Intervention Project, can be used to describe the interventions that nurses perform. It includes seven domains and 30 classes of interventions (see the module on Informatics for further information). Nursing interventions are classified as independent, or nurse initiated; dependent, or physician initiated; and collaborative, or involving other providers (e.g., physical therapist) involved in the patient's treatments.

Independent interventions are those activities that nurses are licensed to do within their scope of practice; in other words, areas of healthcare that are unique to nursing and separate and distinct from medical management. These interventions include physical care, ongoing assessment, emotional support and comfort, teaching, counseling, environmental management, and making referrals to other healthcare professionals. For example, most patients with a nursing diagnosis of pain have medical orders for analgesics, but many independent nursing interventions also can alleviate pain (e.g., guided imagery or teaching a patient to "splint" an incision using a pillow). Recall that many nursing diagnoses are patient problems that can be treated primarily by independent nursing interventions. In performing an autonomous activity, the nurse determines that the patient requires certain nursing interventions. The nurse either carries these out or delegates them to other nursing personnel, and is accountable or responsible for the decision and the actions (see the module on Accountability for further information). An example of an independent action is planning and providing special mouth care for a patient after diagnosing impaired oral mucous membranes.

Collaborative interventions encompass **dependent interventions** employed by the nurse under a physician's orders, under supervision, or according to specified routines

TABLE 36-14 Examples of Typical Nursing Interventions Based on Nursing Diagnosis and Etiology

Type of Nursing Diagnosis	Etiology	Nursing Interventions
Problem focused	<i>Acute Pain</i> related to surgical site	<ul style="list-style-type: none"> ■ Assess pain level using a pain rating scale of 0–10 at frequent intervals. ■ Give ketorolac 15 mg IV every 6 hours prn pain × 5 days.
Risk	<i>Risk for Falls</i> related to use of walker	<ul style="list-style-type: none"> ■ Assess ability to move when using the walker. ■ Keep area from bed to bathroom free from clutter.
Health promotion	<i>Readiness for Enhanced Parenting</i> related to newborn in the home	<ul style="list-style-type: none"> ■ Assess parents' feelings of impact of having a newborn in the home. ■ Discuss infant stimulation techniques with both parents.

and protocols, as well as actions the nurse carries out in collaboration with other healthcare team members, such as physical therapists, social workers, dietitians, and physicians. Collaborative nursing activities reflect the overlapping responsibilities of, and cooperative relationships among, healthcare personnel and demonstrate the benefits of multidisciplinary patient care. For example, the physician might order physical therapy to teach the patient crutch-walking. The nurse would be responsible for informing the physical therapy department and for coordinating the patient's care to include the physical therapy sessions. When the patient returns to the nursing unit, the nurse would assist with crutch-walking and collaborate with the physical therapist to evaluate the patient's progress.

Healthcare providers' prescriptions commonly direct nurses to provide medications, IV therapy, diagnostic tests, diet, and activity for patients. The nurse is responsible for assessing the need for, explaining, and administering medical orders. Nursing interventions should be written to customize the medical order based on the individual patient. For example, instead of writing "Administer NSAID as ordered" as an intervention, the nurse can write "Give ketorolac 15 mg IV every 6 hours prn pain × 5 days as prescribed by physician."

The amount of time the nurse spends in an independent versus a collaborative or dependent role varies according to the clinical area, type of facility, and specific position of the nurse.

Considerations When
Selecting Interventions

Usually several potential interventions can be identified for each nursing goal. The nurse's task is to select those that are most likely to achieve the desired patient outcomes. There is also a need to prioritize potential interventions and include the patient's input. Weighing the pros and cons of each intervention can help the nurse make these decisions. For example, "Provide accurate information about diabetes" as an

intervention could result in any one of the following patient responses:

- Increased anxiety
- Decreased anxiety
- Wish to talk with the primary care provider
- Desire to leave the hospital
- Relaxation.

Determining the pros and cons of each intervention requires nursing knowledge and experience. For example, the nurse's experience may suggest that providing information the night before the patient's surgery may increase the patient's worry and tension, whereas maintaining the usual rituals before sleep is more effective. The nurse might then consider providing the information several days before surgery. See examples of priority nursing interventions for the patient in **Table 36-15** >>.

The following guidelines can help the nurse choose the most appropriate priority nursing interventions to support patients in reaching their goal. Interventions need to be:

- Safe and appropriate for the individual patient's age, health, and condition (see the Lifespan Considerations feature).
- Achievable with the resources available. For example, a home care nurse might wish to include an intervention for an older adult patient to "check blood glucose daily," but in order for that to occur the patient must have intact sight, cognition, and memory to carry this out independently, or daily visits from a home care nurse must be available and affordable.
- Congruent with the patient's values, beliefs, and culture (see Focus on Diversity and Culture).
- Congruent with other therapies (e.g., if the patient is not permitted food, the strategy of an evening snack must be deferred until health permits).

TABLE 36-15 Examples of Priority Nursing Interventions

Nursing Interventions	Rationale
Nursing Diagnosis: <i>Ineffective Airway Clearance</i> related to viscous secretions and shallow chest expansion secondary to pneumonia	
Monitor respiratory status q4h: rate, depth, effort, skin color, mucous membranes, lung sounds, amount and color of sputum, and sensorium.	To identify progress toward or away from goal (i.e., pallor, cyanosis, lethargy, and drowsiness).
Monitor vital signs q4h: temperature, pulse, respiratory rate, blood pressure, and oxygen saturation.	To identify changes in vital signs, which may indicate changes in the patient's condition.
Administer oxygen at 2 LPM via nasal cannula as prescribed by physician.	Supplemental oxygen makes more oxygen available to the cells, which reduces the work of breathing.
Maintain in Fowler or semi-Fowler position.	Gravity allows for fuller lung expansion by decreasing pressure of abdomen on diaphragm.
Administer prescribed antibiotic to maintain therapeutic blood level.	Resolves infection by bactericidal effect.
Administer prescribed expectorant.	Helps loosen secretions so they can be coughed up and expelled.
Administer prescribed analgesic.	Controls pleuritic pain, enabling patient to increase thoracic expansion.
Encourage fluids by mouth (except when contraindicated by medical conditions such as cardiovascular or renal problems).	Helps liquefy the mucus, making it easier to cough up and expel.
Instruct in breathing and coughing techniques. Remind patient to perform, and assist as needed q2-3h.	To enable patient to cough up secretions.

Focus on Diversity and Culture

Cultural Considerations for Nursing Interventions

Patients will have their own cultural beliefs and values that need to be taken into consideration when selecting interventions. For example, patients who have strict dietary practices, such as not eating meat, will require advanced planning if their health problem requires dietary restrictions. Similarly, cultures that require daily care to be given by an individual of the same gender may require the nursing staff to reassign nurses to accommodate this request. In addition, patients who have strong religious beliefs may benefit from interventions related to prayer and meditation, whereas these same interventions would not be helpful for patients who do not have religious beliefs. Each step of the nursing process is important for providing culturally competent care. The assessment phase should be used to identify cultural practices through observation and interview questions. The diagnosis phase can be used to list nursing diagnoses that relate to cultural factors, such as *Spiritual Distress* or *Readiness for Enhanced Religiosity*. The planning and implementation phases should consider the patient's normal cultural practices and incorporate them into the plan of care. The patient has a greater chance of meeting goals and having positive outcomes if the interventions the nurse selects are consistent with the patient's values, beliefs, and practices.

- Based on current best nursing research evidence (see the module on Evidence-Based Practice for further information).
- Within established standards of care as determined by state laws, professional associations (e.g., ANA), and the policies of the facility. Many agencies have policies to guide the activities of health professionals and to safeguard patients. For example, there may be policies for visiting hours and procedures to follow for the patient who has had a cardiac arrest.

Writing a Nursing Intervention

After choosing the best priority nursing interventions, the nurse writes them in the patient's nursing plan of care. Interventions are dated when they are written and then reviewed regularly. Common characteristics of nursing interventions include that they:

- Are patient centered
- Have a specific and concise single action
- Include detailed information about the action (i.e., when, how, time, and where)
- Are realistic for the individual patient
- Are relevant to helping patient reach goal set in planning phase

Only the top 3–5 priority interventions are usually listed for each nursing diagnosis (instead of the 6–10 that could be listed). Nursing students often include a rationale for each selected intervention as they are learning about nursing actions expected with patient conditions and diseases. The

following table shows examples of poorly and correctly written interventions:

Poorly Written Intervention	Correctly Written Intervention
Tell the patient about insulin.	Explain to the patient the actions of insulin.
Assess edema of left ankle daily.	Measure and record patient's left ankle circumference daily at 0800.
Apply dressing to left leg.	Change spiral dressing to left leg every shift as needed.
Give pain medication as needed.	Give acetaminophen 325 mg/oxycodone 5 mg 1 tablet PO 30 minutes prior to going to physical therapy and every 6 hours prn per physician order.

The Process of Implementation

Implementation refers to doing the actions in the interventions. The process of implementation commonly includes the following:

- Preassessment of the patient
- Determining the nurse's need for assistance
- Implementing the nursing interventions
- Supervising any delegated care
- Documenting nursing actions.

Preassessment of the Patient

Just before implementing an intervention, the nurse must reassess the patient to make sure the intervention is still needed and appropriate because the patient's condition may have changed. For example, a patient has a nursing diagnosis of *Disturbed Sleep Pattern* related to anxiety and unfamiliar surroundings. During rounds, the nurse discovers that the patient is sleeping; the nurse decides to defer the back massage intervention that had been planned as a relaxation strategy.

New data may indicate a need to change the priorities of care or the nursing activities. For example, a nurse begins to teach a patient who has diabetes how to give himself insulin injections. Shortly after beginning the teaching, the nurse realizes that the patient is not concentrating on the lesson. Subsequent discussion reveals that he is worried about his eyesight and fears he is going blind. Realizing that the patient's level of stress is interfering with his learning, the nurse ends the lesson and arranges for a primary care provider to examine the patient's eyes. The nurse also provides supportive communication to help alleviate the patient's stress.

Determining the Nurse's Need for Assistance

When implementing some nursing interventions, the nurse may require assistance for one or more of the following reasons:

- The nurse is unable to implement the nursing activity safely or efficiently alone (e.g., ambulating a patient who is obese and needs assistance).
- Assistance would reduce stress on the patient (e.g., turning an individual who experiences acute pain when moved).

- The nurse lacks the knowledge or skills to implement a particular nursing activity (e.g., a nurse who is not familiar with a particular type of orthopedic traction equipment needs assistance the first time turning the patient).

Implementing Nursing Interventions

Before beginning implementation, explain to the patient what interventions will be done, what sensations to expect, what the patient is expected to do, and the purpose of the intervention. For many nursing activities, it is important to ensure the patient's privacy by closing doors, pulling curtains, or draping the patient. The number and types of direct nursing interventions are almost unlimited and include coordination of patient care. Interventions involve scheduling patient contacts with other healthcare providers (e.g., laboratory and x-ray technicians, physical and respiratory therapists) and serving as a liaison among the members of the healthcare team. When implementing interventions, nurses should follow these guidelines:

- **Base nursing interventions on scientific knowledge, nursing research evidence, and professional standards of care.** The nurse must be aware of the scientific rationale as well as possible side effects or complications of all interventions. For example, a patient prefers to take an oral medication after meals; however, this medication is not absorbed well in the presence of food. Therefore, the nurse will need to explain why this preference cannot be honored.
- **Clearly understand the interventions to be implemented and question any that are not understood.** The nurse is responsible for intelligent implementation of physician-ordered interventions in the nursing plan of care. This requires knowledge of each intervention, its purpose in the patient's plan of care, any contraindications (e.g., allergies), and any changes in the patient's condition that may affect the order.
- **Adapt activities to the individual patient.** A patient's beliefs, values, age (chronologic and developmental), health status, and environment are factors that can affect the success of a nursing action. For example, the nurse determines that a patient chokes when swallowing pills, so she consults with the physician to change the order to a liquid form of the medication.
- **Implement safe care.** For example, when changing a sterile dressing, the nurse practices sterile technique to prevent infection; when giving a medication, the nurse follows the six rights of safe medication administration.
- **Provide teaching, support, and comfort.** The nurse should always explain the purpose of interventions, what the patient will experience, and how the patient can participate. The patient must have sufficient knowledge to agree to the plan of care and to be able to assume responsibility for as much self-care as possible.
- **Respect the patient's ethnic background and cultural preferences.** The nurse must always view the patient as a whole and give consideration to the patient's preferences. For example, whenever possible, the nurse honors the patient's expressed preference that interventions be planned for times that fit with the patient's usual schedule of visitors, work, sleep, eating, prayer, or meditation.

- **Respect the dignity of the patient and enhance the patient's self-esteem** by providing privacy and encouraging patients to make their own decisions as appropriate.
- **Encourage patients to participate actively in implementing nursing interventions.** Active participation enhances the patient's sense of independence and control. However, patients vary in the degree of participation they desire. Some want total involvement in their care, whereas others prefer little involvement. The amount of active involvement may be related to the severity of the illness; the patient's culture; or the patient's fear, understanding of the illness, and understanding of the intervention.

Delegation

Delegating patient care and assigning tasks are important responsibilities for registered nurses because healthcare facilities use licensed practical nurses and many unlicensed assistive personnel (UAP). To delegate appropriately, the nurse must match the needs of the patient and family with the scope of practice of the available caregivers. The RN remains responsible for making sure delegated tasks are carried out properly.

Other caregivers may be required to communicate their activities to the nurse by documenting them on the patient's medical record, reporting verbally, filling in a written form, or placing an entry in the patient's electronic medical record. The nurse validates and responds to any adverse findings or patient responses. This may involve modifying the nursing plan of care. For example, UAP may perform tasks such as measuring intake and output, but the RN is still responsible for analyzing data, planning care, and evaluating outcomes (see the module on Managing Care for further information).

Documentation

After carrying out the nursing activities, the nurse completes the implementation phase by recording the interventions performed and patient responses in the nursing progress notes. Nursing actions are communicated verbally, in writing, or by electronic entry. When a patient's health is changing rapidly, the charge nurse and/or the physician may want to be kept up to date with verbal reports. Nurses also report patient status to nursing colleagues at change of shift (see the module on Communication for further information).

Skills Necessary for Implementation

To implement the nursing plan of care successfully, nurses need several kinds of skills: cognitive (knowledge), interpersonal (attitudes), and technical (skills). Although these skills are distinct from one another, nurses use them in various combinations and with different emphasis depending on the activity. For instance, when inserting a urinary catheter, the nurse needs cognitive knowledge of the principles and steps of the procedure, interpersonal skills to inform and reassure the patient, and technical skill in draping the patient and manipulating the equipment.

Cognitive skills include problem solving, decision making, critical thinking, and creativity. They are crucial to safe, intelligent nursing care.

Interpersonal skills are the verbal and nonverbal communication methods nurses use when interacting with the patient or family. The effectiveness of a nursing action often depends largely on the nurse's ability to use therapeutic communication. A nurse also needs interpersonal skills to work effectively with others as a member of a healthcare team (see the module on Communication for further information). Interpersonal skills are necessary for all nursing activities and reflect knowledge, attitudes, feelings, interest, and appreciation of the patient's cultural values and lifestyle as well as the cultural and ethnic differences among fellow healthcare professionals.

Technical skills are purposeful, "hands-on" skills such as manipulating equipment; giving injections; bandaging; and moving, lifting, and repositioning patients. These skills are also called procedural or psychomotor skills. Technical skills require knowledge and, frequently, manual dexterity. The number of technical skills expected of a nurse has greatly increased in recent years because of the advances in the use of technology, especially in acute care hospitals.

Relationship to Other Nursing Process Phases

The first three phases of the nursing process—assessment, nursing diagnosis, and goal planning—provide the basis for the nursing actions performed during the implementation of interventions phase. In turn, the implementation phase provides the actual nursing activities and patient responses that are examined in the final phase, the evaluation phase. Using data acquired during assessment, the nurse can individualize the care given during the implementation phase.

While implementing nursing care, the nurse continues to reassess the patient at every contact, gathering data about the patient's responses to the nursing actions and about any new problems that may develop. Some routine nursing activities present new assessment data for the nurse making observations. For example, while bathing an older adult patient, the nurse observes a reddened area on the patient's sacrum. Or, when emptying a urinary catheter bag, the nurse measures 200 mL of foul-smelling, cloudy, brown urine.

Case Study » Part 4

The goal for Mrs. Aquilini is "The patient will drink 3000 mL of fluids daily by 8/12." Nurse Medina and Mrs. Aquilini are now discussing interventions that will help Mrs. Aquilini reach her goal. Here is the list of potential interventions they have come up with:

- Perform postural drainage daily.
- Record daily weights.
- Have Mrs. Aquilini's favorite beverages available so she can drink them frequently.
- Do coughing and deep breathing exercises every 2 hours.
- Have Mrs. Aquilini's favorite snacks readily available.
- Encourage Mrs. Aquilini to drink a variety of beverages so she does not get bored with water.
- Keep a tally of how much Mrs. Aquilini is drinking and urinating each shift.
- Assess sputum for consistency, color, amount, and odor.

Figure 36-12 » Implementation: Mrs. Aquilini agrees to practice deep breathing exercises q3h during the day. In addition, she verbalizes awareness of the need to increase her fluid intake and to plan her morning activities to accommodate postural drainage.

Nurse Medina explains to Mrs. Aquilini that they need to select the top four priorities from this list to add to her plan of care (**Figure 36-12 »**). She further explains the importance of assessment to measure progress toward reaching the goal. Together, they decide these are the top four priorities:

- Measure intake and output every shift.
- Have Mrs. Aquilini's favorite beverages available so she can drink them frequently.
- Do coughing and deep breathing exercises every 3 hours.
- Perform postural drainage daily.

Clinical Reasoning Questions Level I

1. What is the importance of conducting an assessment before performing any interventions?
2. Would you have selected other interventions for Mrs. Aquilini? If so, what are they and why would you have selected them?

Clinical Reasoning Questions Level II

3. Which of the interventions listed are independent interventions nurses can do without physician orders?
4. Why do you think assessment of the sputum for consistency, color, amount, and odor was not selected as an intervention specific to helping Mrs. Aquilini reach her goal?

Evaluation

After implementing nursing care, the nurse evaluates the desired outcomes. In this context, evaluation is a planned, ongoing, purposeful activity in which patients and healthcare professionals determine (a) the patient's progress toward achievement of goals/outcomes and (b) the effectiveness of the nursing plan of care. On the basis of this evaluation, the plan of care is continued, modified, or terminated. As in all phases of the nursing process, patients and support persons are encouraged to participate as much as possible.

Evaluation continues until the patient achieves the health goals or is discharged from nursing care. Evaluation

conducted during or immediately after implementation of a nursing action enables the nurse to make on-the-spot modifications to an intervention. Evaluation performed at specified intervals (e.g., once a week for the home care patient) shows the extent of progress toward goal achievement and enables the nurse to correct any deficiencies and modify the care plan as needed. Evaluation at discharge includes the status of goal achievement and the patient's self-care abilities with regard to follow-up care. Most facilities have a special discharge record for this evaluation.

Through evaluation, nurses demonstrate responsibility and accountability for their actions, indicate interest in the results of the nursing activities, and demonstrate a desire not to perpetuate ineffective actions but to adopt more effective interventions. During the evaluation process, the nurse determines whether the nursing interventions had any relation to the patient achieving his or her outcomes. It should never be assumed that a nursing action was the cause of or the only factor in meeting, partially meeting, or not meeting a goal.

Clinical Example E

Ruth Horowitz, a patient with obesity, needed to lose 14 kg (30 lb). When the nurse and Mrs. Horowitz drew up a plan of care, one goal was "Lose 1.4 kg (3 lb) in 4 weeks." A nursing intervention listed in the plan of care was "Explain how to plan and prepare a 1200-calorie diet." Four weeks later, Mrs. Horowitz weighed herself and had lost 1.8 kg (4 lb). The goal had been met—in fact, exceeded. It is easy to assume that the nursing intervention was highly effective. However, it is important to collect more data before drawing that conclusion. On questioning Mrs. Horowitz, the nurse might find any of the following: (a) She planned a 1200-calorie diet and prepared and ate the food; (b) she planned a 1200-calorie diet but did not prepare the correct food; or (c) she did not understand how to plan a 1200-calorie diet so she did not bother with it.

If the first possibility is found to be true, the nurse can safely judge that the nursing intervention "Explain how to plan and prepare a 1200-calorie diet" was effective in helping Mrs. Horowitz lose weight. However, if the nurse learns that either the second or third possibility actually happened, then it must be assumed that the nursing strategy did not affect the outcome. The next step for the nurse is to collect data about what Mrs. Horowitz actually did to lose weight. It is important to establish the relationship (or lack thereof) of the nursing actions to the patient responses.

Critical Thinking Questions

1. How might a nurse explain how to plan and prepare a 1200-calorie diet?
2. If a SMART goal is specific, measurable, attainable, realistic, and time-limited, then how do these criteria apply to the statement that "Ruth Horowitz, a patient with obesity, needs to lose 14 kg (30 lb)"?
3. If Ruth did not prepare the correct food, should the goal be explained more practically, revised, or abandoned?
4. What questions should the nurse ask to determine how Ruth lost weight if she did not follow her diet plan?
5. If Ruth did not understand how to plan and prepare the 1200-calorie diet, what should the nurse do first to determine how to better explain the practical steps involved?
6. What are potential indications that the problem might be Ruth's attitude and not her intellectual understanding of the practical issues involved in the 1200-calorie diet?

Drawing Conclusions

The nurse uses judgment about goal achievement to determine whether the plan of care was effective in resolving, reducing, or preventing the nursing diagnosis. When goals have been met, the nurse can draw one of the following conclusions about the status of the patient's problem:

- The actual problem stated in the nursing diagnosis has been resolved, or the potential problem is being prevented and the risk factors no longer exist. In these instances, the nurse documents that the goals have been met and discontinues the care for the problem.
- The risk problem stated in the nursing diagnosis is being prevented, but the risk factors are still present. In this case, the nurse keeps the problem on the plan of care.
- The actual problem still exists even though some goals are being met. For example, a desired goal on a patient's care plan is "Will drink 3000 mL of fluid daily." Even though the data may show this goal has been achieved, other data, for example the presence of dry oral mucous membranes, may indicate that the patient is still experiencing deficient fluid volume. Therefore, the nursing interventions must be continued even though this one goal was met.

When goals have been partially met or when goals have not been met, two conclusions can be drawn:

- The plan of care needs to be revised, since the problem is only partially resolved. The revisions may need to occur during the assessment, nursing diagnosis, planning, or implementation phase.

OR

- The plan of care does not need revision because the patient merely needs more time to achieve the previously established goal(s). To make this decision, the nurse must assess why the goals are being only partially achieved, including whether the evaluation was conducted too soon.

Developing an Evaluation

The nurse collects data so that conclusions can be drawn about whether goals have been met. It is usually necessary to collect both objective and subjective data. Some data may require interpretation. Examples of objective data that may require interpretation are the degree of tissue turgor of a dehydrated patient or the degree of restlessness of a patient with pain. Examples of subjective data that may need interpretation include complaints of nausea or pain by the patient. When interpreting subjective data, the nurse must rely on either (a) the patient's statements (e.g., "My pain is worse now than it was after breakfast") or (b) objective indicators of the subjective data, even though these indicators may require further interpretation (e.g., decreased restlessness, decreased pulse and respiratory rates, and relaxed facial muscles as indicators of pain relief). Data must be recorded concisely and accurately to facilitate the next part of the evaluation process.

If the goal has been written following the guidelines given in this module, it will be relatively simple to determine

whether a goal has been met. Both the nurse and patient play an active role in comparing the patient's actual responses with the desired outcomes. Did the patient drink 3000 mL of fluid in 24 hours? Did the patient walk unassisted the specified distance per day? When determining whether a goal has been achieved, the nurse can draw one of three possible conclusions:

1. The goal was met; that is, the patient's response is the same as the desired outcome.
2. The goal was partially met; that is, either a short-term goal was achieved but the long-term goal was not, or the desired outcome was only partially attained.
3. The goal was not met; that is, the patient did not achieve the goal within the time frame.

Writing an Evaluation

After determining whether a goal has been met, the nurse writes an evaluation statement (either on the care plan or in the nurse's notes). An **evaluation statement** consists of the following information:

- Date and time evaluation was done
- A conclusion statement about whether the goal was met, partially met, or not met
- A supporting statement giving the results of how the patient did or did not achieve the goal.

Here are examples of evaluation statements:

Date and Time of Evaluation	Conclusion Statement	Supporting Statement
12/3, 1345	Goal met.	Patient walked with cane 20 feet down hallway.
9/22, 0900	Goal partially met.	Patient is able to identify three foods instead of five foods high in sugar content.
5/14, 1030	Goal not met.	Patient did not change the dressing on his right arm using aseptic technique.

Continuing, Modifying, or Terminating the Nursing Plan of Care

After drawing conclusions about the status of the patient's problems, the nurse modifies the plan of care as needed. Depending on the facility, modifications may be made by drawing a line through portions of the plan of care or writing "discontinued," "goal met," or "problem resolved" and the date and time.

Whether or not goals were met, a number of decisions need to be made about continuing, modifying, or terminating nursing care for each problem. See **Table 36-16** » for a checklist to use when reviewing a care plan. Although the checklist uses a closed, yes-or-no format, its only intent is to identify areas that require the nurse's further examination.

TABLE 36-16 Evaluation Checklist

Phase of Nursing Process	Checklist
Assessment	<p>____ Are data complete, accurate, and validated?</p> <p>____ Do new data require changes in the care plan?</p>
Diagnosis	<p>____ Are nursing diagnoses relevant and accurate?</p> <p>____ Are nursing diagnoses supported by the data?</p> <p>____ Has problem status changed (i.e., potential, actual, risk)?</p> <p>____ Are the diagnoses stated clearly and in the correct format?</p> <p>____ Have any nursing diagnoses been resolved?</p>
Planning	<p>Desired Outcomes</p> <p>____ Do new nursing diagnoses require new goals?</p> <p>____ Are goals realistic?</p> <p>____ Was enough time allowed for goal achievement?</p> <p>____ Do the goals address all aspects of the problem?</p> <p>____ Does the patient still concur with the goals?</p> <p>____ Have patient priorities changed?</p> <p>Nursing Interventions</p> <p>____ Do nursing interventions need to be written for new nursing diagnoses or new goals?</p> <p>____ Do the nursing interventions seem to be related to the stated goals?</p> <p>____ Is there a rationale to justify each nursing diagnosis?</p> <p>____ Are the nursing interventions clear, specific, and detailed?</p> <p>____ Are new resources available?</p> <p>____ Do the nursing interventions address all aspects of the patient's goals?</p> <p>____ Were the nursing interventions actually carried out?</p>
Implementation	<p>____ Was patient input obtained at each step of the nursing process?</p> <p>____ Were goals and nursing interventions acceptable to the patient?</p> <p>____ Did the caregivers have the knowledge and skill to perform the interventions correctly?</p> <p>____ Were explanations given to the patient prior to implementing?</p>

Before making modifications, the nurse must determine whether the plan as a whole was not completely effective. This requires a review of the entire plan of care and a critique of each step of the nursing process involved in its development.

Assessment

Incomplete or incorrect data influence all subsequent steps of the nursing process and plan of care. If data are incomplete, the nurse needs to reassess the patient and record the new data. In some instances, new data may indicate the need for new nursing diagnoses, new goals, and new nursing interventions.

Nursing Diagnosis

If the data were incomplete, new nursing diagnostic statements may be required. If the data were complete, the nurse needs to analyze whether the problems were identified correctly and whether the nursing diagnoses were relevant to the information collected. After making judgments about problem status, the nurse revises or adds new nursing diagnoses as needed to reflect current patient data.

Revising Patient Goals

If a nursing diagnosis was inaccurate, the goal statement(s) will need revision. If the nursing diagnosis was appropriate, the nurse then checks whether the goal was realistic and attainable. Unrealistic goals require correction. The nurse should also determine whether priorities have changed and whether the patient still agrees with the priorities. For example, the time frame for a specific amount of weight loss was possibly too short and should be extended. Goals must also be written for any new nursing diagnoses.

Selecting New Nursing Interventions

The nurse investigates whether the nursing interventions were appropriate for goal achievement and whether the priority nursing interventions were selected. Even when diagnoses and goals were appropriate, the nursing interventions selected may not have been the best ones to achieve the goal. New nursing interventions may reflect changes in the amount of nursing care the patient needs, scheduling changes, or rearranging nursing actions to group similar activities or to permit longer rest or activity periods for the patient. For example, for a patient who wishes to stop smoking, many potential interventions exist. If medication was prescribed but the patient is still smoking, a behavioral intervention such as group counseling may need to be added. If new nursing diagnoses have been written, then new nursing interventions will also be necessary.

Method of Implementation

Even if all sections of the plan of care appear to be satisfactory, the manner in which the plan was implemented may have interfered with goal achievement. Before selecting new interventions, the nurse should confirm whether the original interventions were carried out. Other personnel may not have carried them out, either because the interventions were unclear or because they were unreasonable in terms of external constraints such as money, staff, time, and equipment.

After making the necessary modifications to the plan of care, the nurse implements the modified plan and begins the nursing process cycle again. Refer to **Table 36-17** » to see how the plan for the patient in the plan of care throughout

this exemplar was modified after evaluation of goal achievement and review of the nursing process. Additions to the care plan are shown in italics. As well as evaluating the patient's response to the nursing plan of care, nurses also evaluate nursing care (see the module on Quality Improvement for further information).

Relationship to Other Nursing Process Phases

Successful evaluation depends on the effectiveness of the phases that precede it. Assessment data must be accurate and complete so that the nurse can formulate appropriate nursing diagnoses and desired goals. The goals must be stated concretely to be useful for evaluating patient responses. And finally, without the implementing phase in which the plan is put into action, there would be nothing to evaluate.

The evaluation phase includes assessment. As previously stated, assessment (data collection) is ongoing and continuous at every patient contact. However, data are collected for different purposes at different points in the nursing process. During the assessment phase, the nurse collects data for the purpose of making diagnoses. During the evaluation phase, the nurse collects data for the purpose of comparing it to the goal developed in the planning phase and making decisions about the effectiveness of the nursing care.

Case Study » Part 5

It is 8/12 and time for Nurse Medina and Mrs. Aquilini to evaluate whether or not Mrs. Aquilini has reached her goal. The first day her intake was 3100 mL and output was 2600 mL; the second day her intake was 3050 mL and output was 2825 mL. Mrs. Aquilini is pleased that she was able to increase her intake of fluids to at least 3000 mL daily. Nurse Medina was happy that Mrs. Aquilini has reached her goal that supports the outcome "to restore an effective breathing pattern." The goal statement was "Goal met. Patient has consumed at least 3000 mL of liquids daily by 8/12." (See **Figure 36-13** ».)

Figure 36-13 » Evaluation: Upon assessment of respiratory excursion, Nurse Medina detects failure of the patient to achieve maximum ventilation. She and Mrs. Aquilini reevaluate the care plan and modify it to increase coughing and deep breathing exercises to q2h.

TABLE 36–17 Example of Evaluation of Outcomes and Goals with Notes about Nursing Interventions

Desired Outcomes	Goal Statements	Nursing Interventions	Note about Nursing Interventions
Nursing Diagnosis: <i>Ineffective Airway Clearance</i> related to viscous secretions and shallow chest expansion secondary to deficient fluid volume, pain, and fatigue			
Respiratory status: gas exchange as evidenced by the following:			<i>Retain nursing interventions to continue to identify progress. Goal status indicates problem not resolved.</i>
■ Absence of pallor and cyanosis (skin and mucous membranes)	Partially met. Skin and mucous membranes not cyanotic, but still pale.	Monitor respiratory status q4h: rate, depth, effort, skin color, mucous membranes, amount and color of sputum.	
■ Use of correct breathing/coughing technique after instruction	Partially met. Uses correct technique when pain well controlled by narcotic analgesics.	Monitor results of blood gases, chest x-ray studies, pulse oximetry, and incentive spirometer volume as available.	
■ Productive cough	Met. Cough productive of moderate amounts of thick, yellow, pink-tinged sputum.	Monitor level of consciousness.	
■ Symmetric chest excursion of at least 4 cm	Not met. Chest excursion 3 cm.	Auscultate lungs q4h.	
■ Lungs clear to auscultation within 48–72 hours	Not met. Scattered inspiratory crackles auscultated throughout right anterior and posterior chest.	Monitor vital signs q4h: TPR, BP, pulse oximetry.	
■ Respirations 12–22/min; pulse <100 bpm	Partially met. Respirations 26/min, pulse 96 bpm.	Instruct in breathing and coughing techniques. Remind to perform and assist q3h. <i>Support and encourage.</i> (4/17/17, JW)	<i>Does not need to be reinstructed because patient demonstrates correct techniques. May still need support and encouragement because of fatigue and pain of breathing.</i>
■ Inhaling normal volume of air on incentive spirometer	Not met. Tidal volume only 350 mL. (Evaluated 4/17/17, JW)	Administer prescribed expectorant; schedule for maximum effectiveness. Maintain Fowler or semi-Fowler position. Administer prescribed analgesics. Notify primary care provider if pain not relieved. Administer oxygen by nasal cannula as prescribed. Provide portable oxygen if patient goes off unit (e.g., for x-ray examination). Assist with postural drainage daily at 0930. On 4/17, teach to continue PRN at home. (4/17/17, JW) Administer prescribed antibiotic to maintain constant blood level. Observe for rash and GI or other side effects.	<i>As soon as patient is hydrated and fever is controlled, she will probably be discharged to self-care at home.</i>

In this plan of care, additions to the care plan are shown in *italics*.

Clinical Reasoning Questions Level I

1. Can you identify the different components in the goal statement?
2. How important is it for Nurse Medina to give Mrs. Aquilini positive feedback on reaching her goal?

Clinical Reasoning Questions Level II

3. If Mrs. Aquilini was not able to reach her goal, what would be Nurse Medina's next action?
4. Once a goal has been met successfully by the patient, what happens to this nursing diagnosis in the plan of care?

stage. Neonates and infants are not able to verbalize their complaints; therefore, collecting “subjective” data relies heavily on parents and caregivers; objective data are based on nursing observations, child–caregiver interactions, and physical assessment. Nevertheless, assessment of the child is a continuous process of collecting and developing a database of information. The nurse analyzes the data and develops accurate nursing diagnoses.

Data analysis supports a nursing diagnosis or diagnoses addressing the child's health-focused problem. Nursing diagnoses may also address risk problems that require interventions in order to decrease the risk of the child or family developing an actual problem. Furthermore, nurses must become familiar with the defining characteristics of diagnoses that address parenting, role conflict, and family processes and observe for cues that accurately support these diagnoses.

Lifespan Considerations

Applying the Nursing Process to Children

Assessment of a child is complex and can vary significantly depending on the child's chronologic age and developmental

After developing nursing diagnoses, the nurse identifies a priority outcome that will be used to evaluate the pediatric patient's plan of care. A priority outcome states that (a) a healthcare problem does not exist and therefore health promotion is stressed; (b) a risk for health dysfunction is present that requires intervention to decrease or eliminate development of an actual problem; (c) an actual health-focused problem is present that requires interventions; or (d) the nurse identifies an outcome that addresses the child and the family's healthcare goals.

In addition to identifying an outcome to evaluate the plan of care, the nurse, the patient, and when applicable, the patient's family develop a plan with patient goals that will evaluate the patient's response to nursing interventions. Once the nurse develops patient- or family-focused goals, the next step is to develop and implement planned interventions and assess feedback by observation or by communication with patient, family, and other providers in order to determine the effectiveness of the interventions. The nurse ensures the child's physical and emotional safety and comfort while nurses or other providers perform interventions.

In the final step of the nursing process, the nurse evaluates data to determine that previously established goals and outcomes have been met and that nursing interventions were appropriate to the child's needs. If the goals have not been met, have been partially met, or have been met because of interventions not included in the plan of care, the nurse considers altering the plan of care, its goals, and its interventions.

Expected outcomes are not reviewed only during the child's hospitalization and at discharge but also at follow-up appointments with the child's pediatrician to evaluate for complete resolution of the actual health problem and, if applicable, the risk problem. School nurses and healthcare providers in daycare centers should also review expected outcomes for children with chronic diseases such as asthma, cystic fibrosis, diabetes, and other chronic diseases.

Clinical Example F

A 4-year-old girl is admitted following emergency surgery for a ruptured appendix. She is awake and alert, but refuses to talk. Her parents have had little sleep for over 24 hours and are extremely anxious.

- Gathering assessment data in this situation requires the nurse to be sensitive to the parents' needs for rest and assurance; at the same time, the nurse must collect information to compile an adequate database that can be used to make appropriate nursing care decisions. Assessment will be problem focused, monitoring the condition of the child as she recovers from surgery and being alert to potential problems.
- Objective data collected include vital signs; level of and response to pain (often called the fifth vital sign); bleeding or discharge from the incision; mobility; integrity of dressings, intravenous lines, catheters, nasogastric tubes, or other medical devices; and affect.
- Since children are a part of families, assessment will include observation of family dynamics and questions that could lead to care of the family system.

Critical Thinking Questions

1. What are the nursing priorities for the 4-year-old child?
2. What are the patient-centered outcomes for the child?
3. What might be an effective method of getting the patient to talk?

4. List three strategies that you would use to allay the parents' anxiety.
5. What objective data about the patient's parents is important for you to assess in relation to her care?

Applying the Nursing Process to Older Adults

Older adults make up the greater portion of all hospital admissions. As the older adult population increases, so does the cultural diversity of this segment of the population (U.S. Department of Health and Human Services, n.d.). Nurses are challenged to provide culturally sensitive care to the older population without cultural or age-related bias and assumptions.

In addition to acute care facilities, older adults function and seek care in various community settings. Nurses are involved in the care of older adults in patients' homes, nursing homes, adult daycare facilities, assisted-living communities, and various categories of subacute care facilities.

Assessment of the older adult in the acute-care or community setting may be complex because of factors related to physical health, cognition, and functionality. However, the nurse should not assume that all older adults have poor memory or impaired functionality; that they all experience depression, social isolation, or financial hardship; or that all older adults are dependent individuals.

The older adult has the potential for a complex and lengthy assessment database as the nurse attempts to organize information that spans a lifetime. For the older adult who may have visual and auditory impairment, assistive devices such as glasses and hearing aids should be used in order to engage in conversation with the nurse and to respond to questions appropriately. Some older adults may respond to questions with slower but accurate answers. The nurse allows the patient time to respond and does not rush the patient or fill in answers based on assumptions about older adults. Some older adult patients may have less than adequate recall due to cognitive dysfunction, medication, or illness. Patients with previous admissions to an institution should have an established database of health-related information that is supplemented and updated with each new admission. Assessment of the older adult should include up-to-date assessment of each patient's strengths, limitations, and means of social support, factors that may change over short periods of time due to illness, change in functionality, and death of spouse or friends.

The nurse must be aware that changes in an older adult's mental status, often reported by family members or caregivers, may indicate an underlying illness. In many cases, older adults do not present with typical signs and symptoms associated with infections or other healthcare problems. An acute change in mental status of the older adult is a cue for a high level of suspicion for a focused health problem and the need for thorough assessment.

The nurse determines the patient's diagnosis or diagnoses based on subjective data and observations from family members and caregivers and from objective data, including observations, physical and cognitive exams, and test results. The nurse then identifies a priority outcome related to the patient's diagnosis and identifies short- and long-term

goals that will be used to evaluate nursing interventions. Outcomes and goals for the older adult must be realistic, individualized and within the realm of the patient's capability. As much as possible, older adult patients should be included when determining goals and interventions related to their care. Although care for every patient is individualized, common goals in caring for older adults revolve around learning needs related to chronic illnesses and medication regimens, safety concerns related to mobility and polypharmacy, and in some cases issues of physical and emotional safety related to caregiver mistreatment or socioeconomic well-being.

Once the nurse develops patient goals, the next step is to develop and implement planned interventions and assess feedback by observation or by communication in order to determine the effectiveness of the interventions. The nurse must take into consideration certain factors that prove challenging when developing interventions for some older adults, including the need for additional time, the patient's level of education and health literacy, the need to interact or teach the patient during the time of day the he or she has the most energy, and the need to use everyday language. The nurse may consider using multiple teaching modes and creativity when educating older adults.

In the final step of the nursing process, the nurse evaluates data to determine that previously established outcomes have been met and that nursing interventions were appropriate to the patient's goals. If the goals have not been met, have been partially met, or have been met because of interventions not included in the plan, the nurse considers altering the plan of care.

Expected outcomes are reviewed during the patient's hospitalization and at discharge. Outcomes should also be evaluated as patients return to the community, because health maintenance minimizes patient readmission. Although many older adults have chronic illnesses and actual health problems, nurses should not focus on these alone. Risk diagnoses are significant to the health of older adults, some of whom are vulnerable to additional health-care, social, and socioeconomic problems.

Healthcare providers often associate health promotion with children and young adults; however, many older adults at various functional levels express the desire to maintain their level of health, improve their health status and functionality, and prevent disease. For older adults who express interest in improving their health status and in preventive care, health promotion diagnoses and interventions should be included in each patient's plan of care.

REVIEW The Nursing Process

RELATE Link the Concepts and Exemplars

Linking the exemplar of the nursing process with the concept of communication:

1. How does the nurse communicate the use of the nursing process when documenting?
2. The nurse is caring for a patient with postoperative pain and administers an analgesic 10 minutes before the end of the shift. How does the nurse communicate the need for evaluation of effectiveness of pain management to the oncoming shift?

Linking the exemplar of the nursing process with the concept of legal issues:

3. How does use of the nursing process in providing and documenting care reduce the nurse's risk of malpractice claims?
4. What legal obligations does the nurse have related to use of the nursing process?

REFLECT Apply Your Knowledge

Dr. Danilo Ocampo is a 74-year-old retired pathologist. He lives in his home with Lydia, his wife of 51 years. Their only child, a son, was killed at age 22 in an automobile crash. Dr. Ocampo was born and raised in the Philippines and came to the United States when he was 23. He is the last living member of his immediate family. He has a few nephews and nieces in the Philippines, but no relatives live nearby.

Dr. Ocampo's health has been declining for the past few years. He has a medical history that includes hypertension, myocardial infarction,

angina, and heart failure. Because of these cardiovascular disorders, he takes multiple medications, including metoprolol; lisinopril; spironolactone; furosemide off and on; K⁺ when taking furosemide; aspirin; isosorbide dinitrate; and nitroglycerin. He understands the pharmaceutical properties of the medications. At times, he is doubtful of the quality of healthcare he receives because of all the medications he has been prescribed. He often does not believe the medications are helpful because he experiences many side effects, and he has been readmitted to the hospital multiple times. He usually feels better after a few days in the hospital but typically checks himself out of the hospital before his physicians are ready to discharge him.

Because Lydia has dementia, most of Dr. Ocampo's time and energy are spent managing their household and taking care of her. He has been resistant to outside help, believing he can care for her better than anyone else does. He maintains a consistent schedule, and he and his wife get along quite well. Although at one time in their lives they were very socially active, at this point, they rarely go out.

Dr. Ocampo has become increasingly short of breath and is very fatigued. He notices his legs have become edematous. He goes to the neighborhood drugstore to use the "self-serve" blood pressure machine and finds his blood pressure to be 152/106 mmHg. He is resistant to the idea of seeing his physician or going to the emergency department for fear of being admitted. Instead, he increases the dose of furosemide and lisinopril by 1 tablet per day and tries to get a bit more rest. A week later when his symptoms fail to improve and seem to worsen slightly, Dr. Ocampo visits his healthcare provider's office and reports his symptoms and increase in medication dosages.

1. What are the priorities of care for Dr. Ocampo?
2. What data would you collect from Dr. Ocampo on initial examination?
3. Develop a nursing plan of care for this patient.

Exemplar 36.B

The Nursing Plan of Care

Exemplar Learning Outcomes

36.B Analyze nursing plans of care as they relate to clinical decision making.

- Define the nursing plan of care.
- Describe the column plan type of nursing care plan.
- Describe the concept map type of nursing care plan.
- Describe the standardized plan type of nursing care plan.
- Describe the clinical pathway type of nursing care plan.

Exemplar Key Terms

Clinical pathway, 2528
 Column plan, 2524
 Concept map, 2524
 Nursing plan of care, 2522
 Standardized plan, 2525

Overview

A **nursing plan of care** is a written or electronic guideline that organizes information about an individual patient or family's care. One plan may include several nursing diagnoses for a single patient. It is important to prioritize nursing diagnoses and to list only three to five nursing diagnoses; this helps the nurse focus on nursing care that provides the best patient outcomes. The RN initiates the plan when the patient is admitted to the facility. The plan of care is then constantly updated throughout the patient's stay in response to changes in the patient's condition and evaluations of goal achievement. Keeping the plan of care current is necessary to ensure appropriate, individualized care for the patient. When the patient is discharged from the facility, the plan is included as part of a patient's permanent record of the care

received and care the patient should have received (see the module on Communication for further information).

Although formats differ from facility to facility, the plan of care is often organized using the five phases of the nursing process (see **Figure 36-14** »). Whether written or electronic, plans have the following purposes:

- Provide individualized patient-centered care to meet the unique needs of each patient.
- Provide for continuity of care through communication with nursing staff and other healthcare providers involved with the care of the patient.
- Inform the nurse about which specific observations or actions need to be documented in the nurse's progress notes about the patient's care.

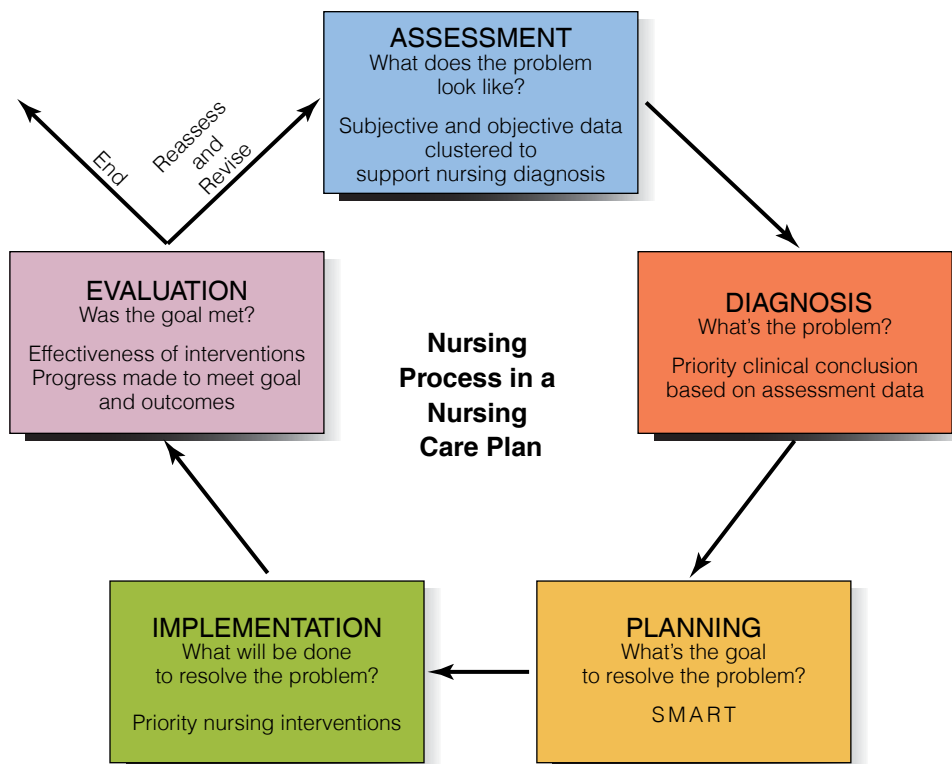

Figure 36-14 » Using the nursing process in a nursing plan of care.

- Provide health insurance companies documented proof for reimbursement amount to pay for services rendered to the patient.
- Provide the nurse with a guide when assigning nursing staff to care for each patient.

Accessibility

Nursing plans of care need to be readily accessible to all healthcare team members involved with the care of the patient. Availability of the plan supports communication with others for better continuity of care. The plan of care may be kept at the bedside but is more commonly kept within the medical record. In most institutions, the nursing plan of care is part of the electronic medical record that requires specific information about the patient’s plan of care. The electronic medical record is accessible to all staff with appropriate access to the patient’s record on all units and departments to which the patient may be transferred. The electronic medical record provides the healthcare team with information about the patient, such as demographic data, routines of daily care (i.e., bathing, nutrition), diagnostic studies, social history, oxygen therapy, monitoring needs, medications and IV fluids, and surgical drains.

Guidelines

The nurse should follow the guidelines in **Table 36–18** » when writing nursing plans of care. Note that the guidelines include specificity and customization.

Clinical Example G

Marlene Fisher is a 52-year-old woman whose husband of 35 years died 5 weeks ago after a long battle with lung cancer. She says that she has come to the clinic today because she does not sleep more than 3 hours at night and feels tired all the time. She tells the nurse that she has lost about 15 pounds since her husband died because she is too tired to fix anything to eat.

Mrs. Fisher has two sons, both of whom attended the funeral, but they have not contacted Mrs. Fisher since then. One lives on the other side of town, and the other lives out of state.

For more than 40 years, Mrs. Fisher attended her place of worship every time the doors were opened for an activity. She also enjoyed singing in the choir. For the past couple of weeks, she has not been able to attend any activities because she doesn’t understand why her husband had to die, and she feels disconnected from her place of worship. She stopped singing at home because she says she “doesn’t feel the music anymore.” Mrs. Fisher says she stays at home every night now to avoid seeing people that are “smiling and happy” when she feels so lost and alone.

Clinical Reasoning Questions Level I

1. What are the significant assessment data for Mrs. Fisher?
2. What related clusters do the significant assessment data form?

Clinical Reasoning Questions Level II

3. What are the top three priority nursing diagnoses from the clustered assessment data?
4. What goal would be appropriate for each of the three nursing diagnoses?
5. What are the top three priority nursing interventions to support Mrs. Fisher reaching her goals?

TABLE 36–18 Guidelines for Writing a Nursing Plan of Care

Guideline	Description
Date and sign the plan.	The date the plan is written is essential for evaluation, review, and future planning. The nurse’s signature or login demonstrates accountability since the effectiveness of nursing actions can be evaluated.
Use category headings: “Assessment,” “Nursing Diagnoses,” “Goals/Desired Outcomes,” “Nursing Interventions,” and “Evaluation.”	Headings may vary slightly with different facilities but are relative to the nursing process phases.
Use approved abbreviations and key words rather than complete sentences to communicate ideas unless facility policy dictates otherwise.	For example, write “Turn/reposition q2h” rather than “Turn and reposition the patient every two hours.” Or, write “Clean wound c– H ₂ O ₂ bid” rather than “Clean the patient’s wound with hydrogen peroxide twice a day, morning and evening.” (See the module on Communication for more information.)
Be specific, short, and concise.	Because nurses are now working shifts of different lengths (e.g., 12- or 8-hour shifts), the nurse must be specific about the timing of an intervention. An intervention reading “Change incisional dressing q shift,” could mean either twice in 24 hours, or three times in 24 hours, depending on the length of the facility’s shifts.
Refer to facility resources, such as procedure books, rather than including all of the steps on a written plan.	For example, write “See unit procedure book for tracheostomy care” or attach a standard nursing plan about such procedures as preoperative or postoperative care.
Customize the plan to include patient’s choices, such as preferences about the times of care and the methods used.	This reinforces the patient’s individuality and sense of control. For example, the written nursing intervention might read “Provide partial bath in the evening per patient’s preference.”
Ensure that the nursing plan incorporates preventive and health maintenance aspects as well as restorative ones.	For example, carrying out the intervention “Provide active assistance ROM (range-of-motion) exercises to affected limbs q2h” prevents joint contractures and maintains muscle strength and joint mobility.
Ensure that the plan contains interventions for ongoing assessment of the patient.	For example, “Inspect incision q8h.”
Include collaborative activities in the plan.	For example, the nurse may write interventions to ask a nutritionist or physical therapist about specific aspects of the patient’s care.
Include plans for the patient’s discharge and health teaching needs.	The nurse begins discharge planning as soon as the patient has been admitted, often consulting and making arrangements with a community health nurse, social worker, and other community agencies to supply patient services, needed equipment, and supplies.

Written nursing plans of care are used in facilities that do not have electronic medical records. Plans can be kept in a separate notebook or with the patient's medical record. Similar to the electronic medical record, written plans of care support communication and continuity of care when patients are transferred from one unit to another or from one facility to another. The plan of care becomes a part of the patient's permanent record upon the patient's discharge from the facility. Each facility decides the format used for the plan of care. Facilities customize the following common types of plans of care for their patients: column plan, concept map, standardized plan, and clinical pathway.

Column Plan

Nursing students learn to develop patients' plans of care and to organize the patients' data from patients assigned to them for learning activities. As a result, care plans developed by students usually are lengthier and more detailed than plans of care used by experienced nurses. Students may be required to give a rationale, or reason, for selecting a particular nursing intervention as a priority. Students may also be required to cite research evidence from literature to support their stated rationale and to develop evidence-based practice habits.

The **column plan** of care uses columns to categorize data for each phase of the nursing process. This type of care plan may include four columns: (a) nursing diagnoses, (b) goals/desired outcomes, (c) nursing interventions, and (d) evaluation. Some agencies use a three-column plan in which evaluation is done in the goals column or in the nurses' notes; other agencies use a five-column plan that adds a column for assessment data preceding the nursing diagnosis column. **Figure 36-15** » shows a five-column framework for a nursing care plan for the patient in Clinical Example G, Mrs. Fisher.

Concept Map

A **concept map** is a visual representation of a nursing plan of care in a patterned diagram with data and ideas. Various

shapes and colors are used to show relationships and connections in combination with lines or arrows. Concept maps are creative, conceptual images of concrete critical thinking. The visual image enhances clinical reasoning by "showing" how nursing diagnoses, goals, interventions, and evaluations relate to each other in a logical pattern. Concept maps can take many different forms and encompass various categories of data according to the creator's interpretation of the patient or health condition. They are an offshoot of mind maps or cognitive maps. A concept map can be a visual guide for analyzing relationships among clinical data to help prioritize meeting patient needs.

The concept map is another way of depicting the nursing plan of care. Concept maps can help nursing students view the patient and his or her problems holistically rather than as a single problem or medical diagnosis. Students are often asked to complete concept maps as a method of learning and demonstrating the links among disease processes, laboratory data, medications, signs and symptoms, risk factors, and other relevant data.

There are many different ways to make a concept map. Post-It notes are useful because they already come in a variety of colors and shapes; they also make it easy to move data around until the concept map is finished. Colored pencils or markers and paper cut into various shapes can be used as well. Software programs are available for creating electronic concept maps, and many websites offer free concept mapping programs.

Hints when making a concept map:

- Follow the sequence of the nursing process phases; always begin with assessment data collection and cluster significant related data to determine nursing diagnoses (see the exemplar on the Nursing Process for further information).
- Keep it simple. The more lines cross each other, the more difficult it is to follow the connections among data.

Assessment	Nursing Diagnosis	Plan	Implementation	Evaluation
<ul style="list-style-type: none"> Doesn't understand why her husband died Stopped attending place of worship because feels disconnected from it Stopped singing in the choir 	<i>Spiritual Distress</i>	Patient will meet with religious adviser by 4/12.	<ul style="list-style-type: none"> Establish therapeutic relationship with patient. Assist patient to cope with lifestyle changes. Assist patient in finding a reason for living. Discuss visit with religious adviser. Encourage patient to talk about her feelings. 	4/12 Goal ongoing—patient has appointment with religious adviser on 4/13.
<ul style="list-style-type: none"> Not sleeping well States she "feels so lost" Lost 15 pounds Not eating well 	<i>Ineffective Coping</i>	Patient will eat three meals a day by 4/8.	<ul style="list-style-type: none"> Assess for risk of hurting self or others. Refer patient to counseling. Discuss sleep promotion behaviors. Have dietitian discuss cooking for one with patient. 	4/8 Goal met—patient has eaten three meals a day × 4 days.
<ul style="list-style-type: none"> No contact with sons since husband's death Husband died 5 weeks ago Avoids people Stays at home every night 	<i>Social Isolation</i>	Patient will phone each son by 4/10.	<ul style="list-style-type: none"> Discuss promotion of social contacts. Assist patient in developing a support system. Support patient in reconnecting with sons. Encourage outside activity—like walking. 	4/10 Goal not met—patient has spoken with only one of her sons.

Figure 36-15 » Five-column nursing plan of care for situational distress.

- Many nursing programs have developed a concept map format for nursing students to follow, but the nurse can still use creativity to individualize patient concept maps.
- Avoid becoming caught up in the artistic expression. Do not spend hours matching colors and shapes and coordinating patterns while developing a concept map: it is a visual representation of important concepts focused on nursing care for best patient outcomes.

Many approaches can be used to build a concept map. Here is an example that is basic and can be expanded if more data are being used:

1. Develop a legend for the concept map by assigning shapes and colors for each nursing process phase and one for other categories of patient information: demographics, outcomes, lab results, risk factors, or medications.
2. Put the shape with the patient's initials, age, gender, and priority medical diagnosis in the middle of the paper to illustrate the patient-centered nature of nursing care.
3. Look at the assessment data, subjective and objective, and then gather and sort the significant clusters. Each piece of significant data goes on one assessment shape. Place the clustered groups around the patient shape.
4. Determine the priority nursing diagnoses that are relative to each of the clusters and place one nursing diagnosis with each of them. Draw connecting lines from each shape with assessment data to the nursing diagnosis for which it is relative.
5. Determine one appropriate goal for each nursing diagnosis cluster and add its shape to the side of the nursing diagnosis cluster. Select priority nursing interventions and label them as independent, dependent, or collaborative for each goal. Write separate interventions on their designated shape and arrange them on the outer side of the nursing diagnosis. Draw connecting lines from each shape with an intervention to the nursing diagnosis for which it is relative.
6. Evaluate whether the goal was met, not met, or partially met, and place the evaluation shape on the side of the nursing diagnosis cluster. It can be located under the goal shape or on the opposite side.
7. The concept map is now complete. **Figure 36-16** » uses the data for Mrs. Fisher from Clinical Example G to build a concept map.

Standardized Plan

A **standardized plan** of care specifies the nursing care for groups of patients with common needs (e.g., all patients with myocardial infarction). These plans can be developed by a standardized care committee composed of facility staff that use both medical and nursing research evidence (see the module on Evidence-Based Practice for more information). Facilities may also purchase standardized plans to complement their policies and procedures. A preprinted plan is time efficient for nurses compared to generating a single plan for a common set of interventions for patients with the same condition. Once the nursing assessment is completed, the standardized plan of care that is appropriate for the patient is selected, and the nurse adds or deletes information

on the generalized care plan to individualize it to the unique needs of a particular patient.

A standardized plan of care frequently includes checklists, blank lines, or empty spaces to allow the nurse to individualize goals and nursing interventions. Standardized plans of care should not be confused with standards of care. Although the two have some similarities, they have important differences.

SAFETY ALERT Nurses must remember that standards of care are not the same as a standardized plan of care. Standards of care are nursing actions for patients that describe achievable nursing care. They define the interventions for which nurses are held accountable. Standards of care are developed by individual health-care facilities for nurses working in the facility. National organizations and agencies, such as the ANA, the Joint Commission, and State Boards of Nursing, also set standards of nursing practice for nurse accountability (see the module on Accountability for further information). A standardized plan of care provides general nursing care for specific medical diseases or conditions. If the nurse determines that following any part of a standardized plan of care would jeopardize a patient's safety or health outcomes, the nurse is responsible for taking appropriate action to ensure the health and safety of the patient by altering or deleting that section of the plan of care.

Standardized care plans are usually categorized according to specific age groups, patient problems, and specialty categories. Standardized plans follow the nursing process phases so nurses are familiar with their format. Regardless of whether plans of care are handwritten, computerized, or standardized, nursing care must be individualized to fit the unique needs of each patient. In practice, a plan of care usually consists of both preprinted and nurse-created sections. The nurse uses standardized care plans for predictable, commonly occurring problems and creates an individual plan for unusual circumstances or problems that require special attention and are unique to the individual patient's needs.

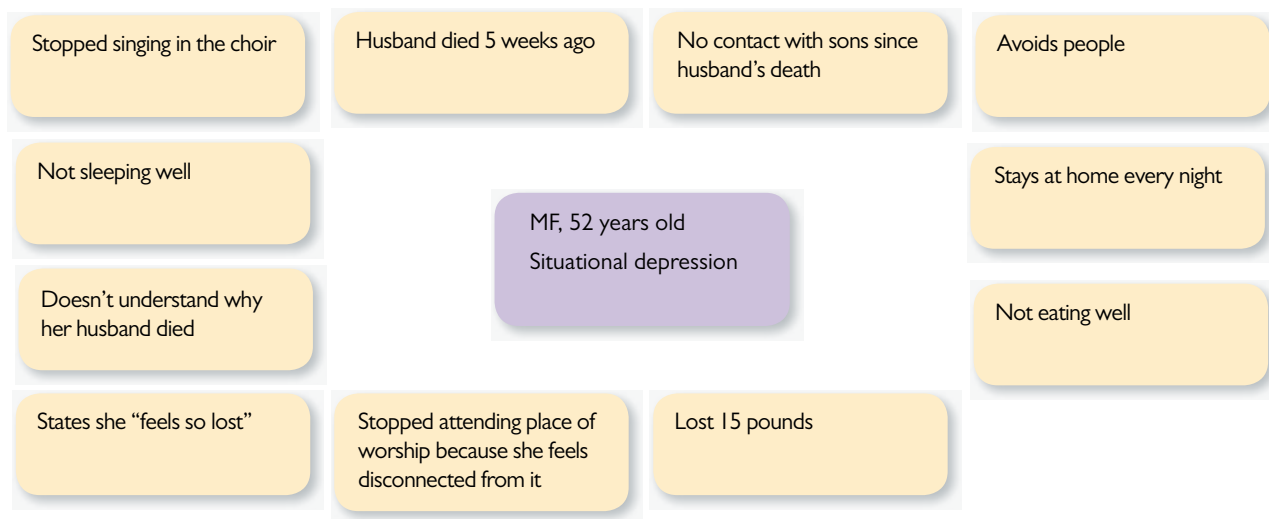

For example, a standardized care plan for "patients with a medical diagnosis of pneumonia" would probably include a nursing diagnosis of *Deficient Fluid Volume* and direct the nurse to assess the patient's hydration status. On a respiratory or medical unit this would be a common nursing diagnosis; therefore, the patient's nurse would be able to obtain a standardized plan directing care commonly needed by patients with deficient fluid volume (see **Figure 36-17** »). However, the nursing diagnosis *Interrupted Family Processes* would not be common to all patients with pneumonia, although it would be needed for a mother with three small children at home. Therefore, the goals and nursing interventions for that diagnosis for that patient would need to be created by the nurse.

SAFETY ALERT Documentation should always be clear, timely, and dated. Nursing documentation, handwritten or electronic, is the primary source of communication between the nurse and other members of the healthcare team. Documentation records nursing assessment, clinical problems, patient and family education, patient response to interventions, and patients' plan of care. Whereas documentation provides the most accurate and complete account of patient care, nursing documentation records nurses' work as well as patient outcomes. In addition, nursing documentation is the primary source for credentialing, accreditation, research, reimbursement, and legal affairs (American Nurses Association, 2010b).

1. Select shapes and/or colors for the concept map, assigning each a label.

2. Start with the patient in the middle of the paper, and cluster significant assessment cues to select priority nursing diagnoses.

3. Add the priority nursing diagnoses and use lines to connect them to the appropriate assessment data.

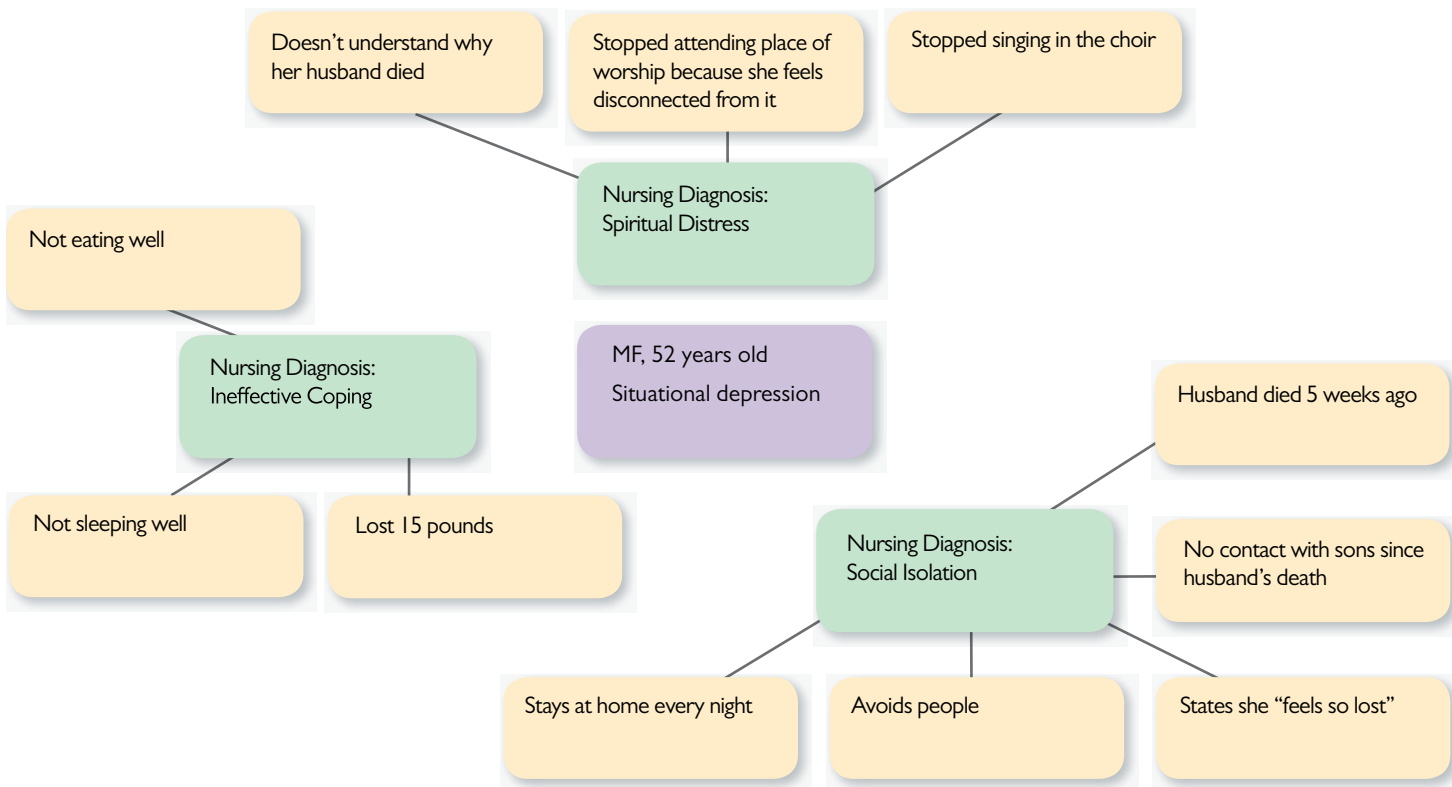

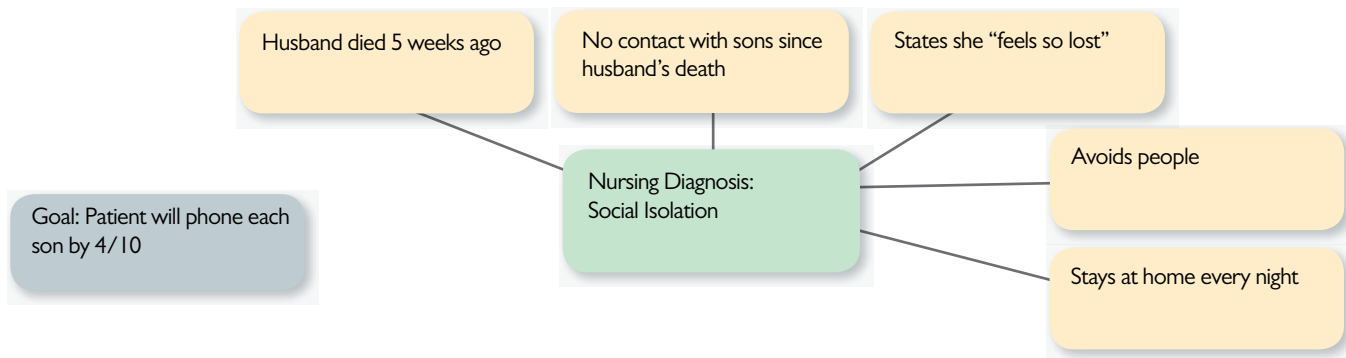

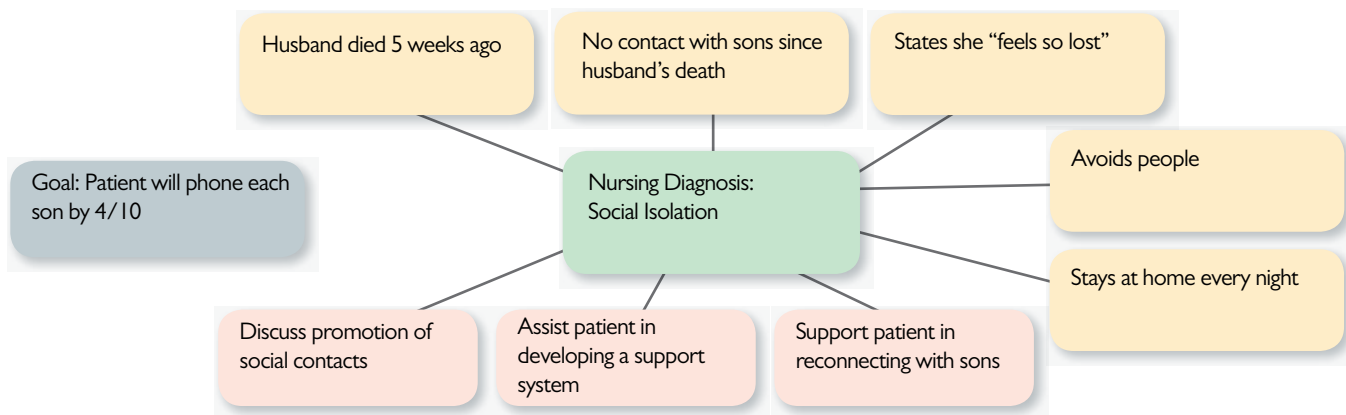

Figure 36-16 » Steps for building a concept map.

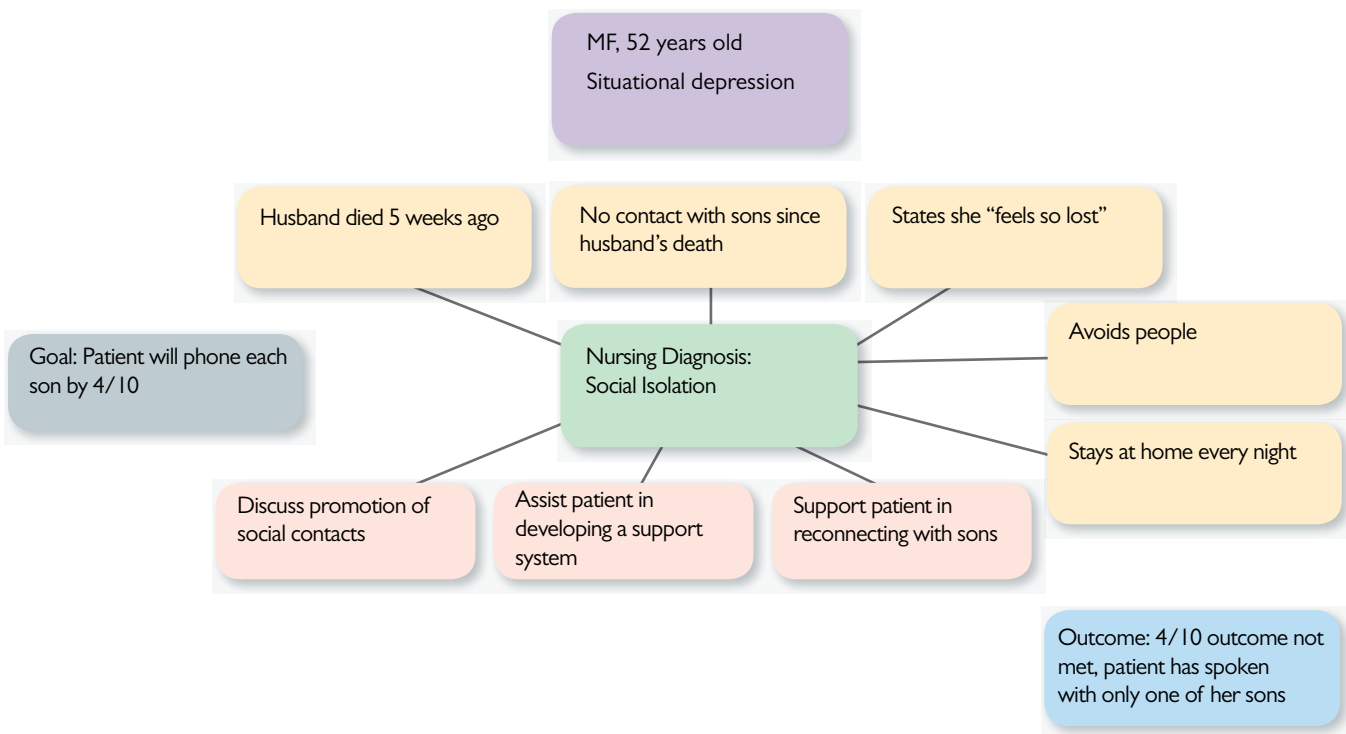

4. Select one or more measurable goals for the patient to work toward that will help the patient resolve the nursing diagnosis.

5. For each nursing diagnosis and corresponding goal(s), determine interventions that will help the patient meet the agreed upon goal(s).

6. At the next healthcare interaction, evaluate whether or not the patient has met the goals (outcomes) and, if not, why.

7. Repeat steps 4 – 6 for the nursing diagnoses of Ineffective Coping and Spiritual Distress. Arrange all the information into clusters with connecting lines, and complete a concept map on your own.

Figure 36-16 » Steps for building a concept map. (continued)

Clinical Pathway

A **clinical pathway** is a standardized, evidence-based, multidisciplinary plan that outlines the expected care required for patients with common, predictable health conditions. To initiate a clinical pathway, the physician writes an order for one that is appropriate for the patient. The clinical pathway documents are part of the patient's permanent record and are integrated into the clinical documentation.

Sometimes clinical pathways are referred to as collaborative plans or case management plans, and they sequence the care that must be given on each day during the projected length of stay for the specific type of condition. They include clinical interventions, time frames for completion, usual expectations of response, and expected outcomes. They are also sometimes called multidisciplinary plans because they include medical treatments to be performed by different types of healthcare providers.

The plan is usually organized with a column for each day, listing the interventions that should be carried out and the patient outcomes that should be achieved on that day. There are as many columns on the multidisciplinary care plan as the preset number of days allowed for the patient's diagnosis-related group (DRG). Clinical pathways do not include detailed nursing activities because they are multidisciplinary in nature. Because all patients are unique, each patient's care will be customized to meet his or her specific needs while keeping the guidelines in

mind. Clinical pathways minimize variance in treatment plans in order to reduce cost, increase efficiency, and improve patient care outcomes. Clinical pathways are frequently used in Canada, Australia, and the United Kingdom (Centre for Policy on Aging, 2014).

Patient-specific clinical pathways are given to patients to help them understand what to expect in terms of time frames, actions, and results as related to DRGs. For example, **Figure 36–18** » is a clinical pathway for a vaginal birth (mother and baby). It includes information about activity, nutrition, medications, treatments, patient teaching, tests, and discharge planning for specific times from delivery time of the baby.

Clinical pathways may be developed as an algorithm or path as shown in the example of **Figure 36–19** ». This clinical pathway is for pediatric patients with asthma and is directed toward the multidisciplinary team. It includes separate assessment and treatment progressive guidelines for the pediatric patient with mild, moderate, severe, and near-death signs and symptoms of asthma. Medications, treatments, and teaching instructions are listed for pediatric patients. The pathway includes information about the assessment, pretreatment, and treatment of these patients, and steps to be taken if the patient has not improved. Pathways like this one are designed to improve the quality of care and outcomes as well as to standardize care provided across clinical disciplines.

Focus on Diversity and Culture

Planning Care with Culture

The nurse develops the patient's plan of care with respect to the patient and family's sociocultural background, including the family's structure and organization, religious values, cultural beliefs, and the way in which culture and ethnicity relate to roles within the family. A patient's plan of care must address the role of family and family function within a specific culture, because after discharge, the family will be involved in the daily care of the patient. Nurses should employ effective communication, a holistic patient perspective, and respectful cultural care when caring for patients of varied cultures. Both in the hospital and at home, dietary recommendations should, as much as possible, fall within the patient's cultural dietary habits; it may be necessary to

consult a dietitian for assistance with regard to dietary changes and recommendations. The nurse should note the patient's religious observances that may require fasting and the manner in which this practice can affect the patient's medication regimen and health. Religious practices may also influence the gender of the nurse who is able to care for the patient during hospitalization. This should also be taken into consideration if the patient is discharged to home with an order for visiting nurse services. In addition, patients who receive skilled nursing and other health-related therapies at home may benefit from having healthcare personnel who speak the same language or who share or have superior understanding of the patient's culture.

REFLECT Apply Your Knowledge

Devon Bynum, an 11-year-old, is admitted to the hospital in sickle cell crisis. This is the first time he has been admitted to a hospital. He

states he hurts all over and rates his pain as 7 out of 10. Devon has been in the emergency department all night and last received morphine 2 mg IV at 0400 for his pain. He is receiving oxygen at 2 liters per minute (LPM) via nasal cannula. He has an IV of D5 ½NS running at 83 mL/hr. His mom, who has been with him throughout the night, is anxious for her son to feel better. His latest vital signs are T 99.3° F; P 122 bpm; R 22/min; BP 100/64 mmHg; and oxygen saturation 93% on oxygen at 2 LPM. He says he is tired and just wants to go to sleep. Devon's mom tells the nurse that she doesn't know how she

will be able to pay the hospital bills. She shares that she is a single parent with two other children at home.

1. What type of nursing plan of care would you use for Devon? Why?
2. Would you include his mom's concern about finances in his plan of care? How?
3. What other healthcare discipline(s) would you expect to include in Devon's plan of care?

Exemplar 36.C Prioritizing Care

Exemplar Learning Outcomes

36.C Analyze prioritizing care as it relates to clinical decision making.

- Describe the need for nurses to prioritize care.
- Describe methods or identifying what to prioritize.
- Describe various processes of categorizing priorities.
- Outline factors to consider when prioritizing care.
- Summarize pitfalls of prioritization.

Overview

The term **priority** refers to using judgment to discern which among competing problems should be addressed immediately. **Prioritizing care** is a process that helps nurses manage time and establish an order for completing responsibilities and care interventions for a single patient or for a group of patients. The ability to set priorities is a critical thinking skill that can optimize a nurse's time and productivity by categorizing responsibilities and care interventions in an order based on significance and urgency. Time is a constant factor in prioritizing care: nurses have only a limited amount of time to make clinical judgments about which interventions to perform and when to do them, whether for one patient or for several patients. Without some forethought and planning, a nurse may work for hours and yet accomplish very little. Nurses must learn to use time and energy wisely in today's busy healthcare settings.

A nurse's workload includes many objectives that need to be completed during each shift. Time management is an important skill that helps the nurse ensure that necessary activities are completed. Nurses can use a variety of approaches to accomplish nursing responsibilities and interventions. Unfortunately, some of these approaches may result in interventions being done poorly, incompletely, late, or not at all.

For example, some nurses simply plow into their work. They complete tasks as they go from patient to patient in no particular order, keeping busy by doing activities to meet patients' needs. They may start at one room and simply work their way down the hallway doing things for their

patients. This strategy raises a number of questions. What about the nursing interventions with time constraints, such as medication administration? Are all nursing interventions equally important? Do all nursing interventions impact patients equally?

Sometimes nurses choose to work on the easiest tasks first, postponing the more challenging, complex tasks for a later time, but they may find themselves rushing to finish the complex tasks during that inevitable "crunch" time. The nurse may decide he or she does not have time to perform an important intervention and leave it undone. A nurse working at a hurried pace experiences an increased stress level, which interferes with clear thinking, clinical judgment, and decision making. As time to complete actions decreases, working at a hurried, task-oriented pace often negatively impacts both the quality of professional performance and the quality of patient care.

Many new nurses have difficulty prioritizing patient care, yet they are afraid to ask questions to get the help they need. New nurses often benefit from adequate orientation and preceptorship that include discussions about delegation, but they also benefit from having a mentor to address issues such as workflow and prioritizing patient care. As new nurses gain confidence, experience, and competency, they develop the ability to distinguish routine tasks from individualized care, they learn to advocate for their patients, and they develop their workflow based on prioritizing patient care (Veerapen & Purkis, 2014).

In contrast to less productive methods of completing activities, nurses can learn to prioritize their actions according

to the importance of tasks and interventions and the appropriate timing for accomplishing them. As a result, interventions that have a high priority will be completed early. Just like learning any new skill, learning to prioritize care will take practice. When developing this skill, nurses have the advantage of being able to transfer other skills they have learned in nursing: assessment, critical thinking, clinical judgment, decision making, planning, implementation, and ongoing evaluation (see the Critical Thinking section earlier in this module for more information).

Identifying What to Prioritize

Nursing strives for quality productivity and patient satisfaction. Three factors can influence patient satisfaction with nursing care: availability of nursing staff to care for patients, the amount of time it takes nursing staff to meet patients' needs, and the quality of the care provided. **Effectiveness** (doing the right things) and **efficiency** (doing things right) are two qualities that impact patient perception of nursing care. Nurses employ effectiveness and efficiency by using the strategies of setting priorities, managing time, and delegating to staff. To support these qualities, nurses need to limit distractions and interruptions. Patients may perceive the nurses' distractions and interruptions as signs of inefficiency and conclude that the actions nurses perform are simply tasks instead of individualized, personal care. When providing patient-centered care, treat all patients with respect, dignity, and necessary attention.

Assessment

"Look before you leap" reflects the need to have accurate information prior to taking action. Setting priorities for nursing care always begins with assessment. Assessment includes observing and asking questions to gather the information necessary for decision making. Helpful assessment data include the following:

- Observing for cues about pace and emotions of staff already working on the unit (e.g., are they relaxed or stressed?).
- After receiving information from the previous nurse in shift report, conducting one's own assessment by making a quick safety check of patients.
- Becoming aware of any patients who have an unstable status, a risk of change in their condition, or who require closer observation.
- Asking if there are any complexities to patient problems.
- Asking about any special safety concerns for the patients (e.g., high risk for falls).
- Making note of routine responsibilities and interventions that have time constraints (e.g., physician rounds at 0900, medication administration at 1000 and 1200, nursing meeting at 1330).
- Knowing how many and what level of nursing staff are available for delegation of tasks to help with patient care. Delegation is the transfer of responsibility and authority for completing an activity to a qualified individual (see the module on Managing Care for additional information), although accountability for the task remains with the nurse.

- Noting the presence (and absence) of necessary resources on the unit (e.g., linen, supplies, and nourishments).
- Asking about patient preferences to take into consideration when providing care.

Airway, breathing, and circulation are vital for life. If a safety risk or physiologic deterioration threatens any one of these functions, the situation may quickly become life threatening without prompt assessment and intervention. Nurses must be able to assess and prioritize threats to these functions as they arise (see **Box 36-3** »).

The Nursing Process

Since the 1950s, the nursing process has been used as a method of organizing nursing care of patients, and this process was made mandatory when it was codified by the ANA in 1973. The steps in the nursing process provide the framework nurses use to determine priorities when working with a single patient or a group of patients (see the exemplar on the Nursing Process for further information).

The National Council of State Boards of Nursing (NCSBN) provides models for states to use when revising their nurse practice acts and nursing administrative rules. The sections covering the scope and standards of nursing practice list the steps of the nursing process that develop a nursing plan of care. These sections also support accountability for clinical judgments, decision making, critical thinking, and competence of interventions in the course of nursing practice (prioritizing care and performing interventions) (NCSBN, 2016). See **Box 36-4** » for two examples of state rules about prioritization of care.

Maslow's Hierarchy of Needs

Maslow's hierarchy of needs is a well-known method of assessing and organizing patients' needs. This hierarchy of needs is typically displayed as a five-level triangle or set of steps (see the module on Stress and Coping for further information). Beginning at the bottom, the levels of need progress from the most basic physiologic needs to more complex psychologic and social needs at the top. The most basic needs include food, air, water, shelter, elimination, and sleep (Cherry, 2015).

According to Maslow, these needs motivate behavior. The first four needs—physiologic, safety, social, and esteem—are sometimes called "deficiency needs" and indicate the patient is experiencing deprivation of one or more of those four needs. Needs on the lower levels must be met before an individual can move to higher levels. The last need, self-actualization, is called a "being need" and does not result from a deficiency, but rather indicates a desire for growth as an individual (Cherry, 2015).

Maslow ranked his hierarchy of needs with essential needs on the first (bottom) level and lowest needs on the last (top) level. Nurses can use Maslow's hierarchy as they establish priorities of patient care. For example, ineffective breathing pattern, a physiologic need, takes priority over body image disturbance, a self-esteem need.

The nursing process and Maslow's hierarchy of needs can be used to guide the nurse in thinking critically about the order in which patient needs should be addressed. Nurses

Box 36–3

Priority Assessment of Safety Risks and Physiologic Deterioration

A nurse walks into a patient's room and finds the patient pulling out his tracheostomy tube. Another nurse walking down the hallway passes the visitors' waiting room and finds a child patient climbing up a high metal file cabinet. A third nurse finds her patient unresponsive, not breathing, and without a pulse. These situations involve safety and physiologic deterioration; all require prompt assessment for the potential to become life threatening. Removal of the tracheostomy tube could leave the patient without a patent airway; the child patient could cause the file cabinet to fall and possibly crush his head; and the patient who is unresponsive with no respirations or pulse could die within minutes. Nurses continuously assess patients in their environments to recognize harmful situations. If the patient is in danger, intervention becomes a priority.

The mnemonic **ABC** represents the essential functions of airway, breathing, and circulation. It provides a guideline for use when assessing a patient. An initial assessment of basic body functions necessary to sustain life precludes a more definitive assessment or any patient intervention (discussed in the module on Perfusion). The initial ABC assessment includes:

Airway: A patent airway so oxygen will have a pathway into the lungs for gas exchange and for carbon dioxide to be expelled from the body

Breathing: An effective breathing pattern and respiratory effort to take in enough oxygen to meet cellular demands for oxygen throughout the body

Circulation: An effective circulatory system to deliver oxygen throughout the body and exchange carbon dioxide and oxygen through the pulmonary circulatory network.

Nurses working in a variety of settings follow priority emergency protocols developed by the American Heart Association (2015) to

standardize CPR. Since its development, the ABCs of CPR have been enhanced and altered by various specialty groups and professional organizations, adding more letters or changing the meaning of the letters; however, ABC is the universally accepted priority in managing life-threatening emergencies.

Another popular enhancement to the basic ABCs mnemonic is to add a D at the end, creating **ABCD** to help define other priority emergency assessments to complete. The meaning of D varies from one organization to another, but D may stand for:

- **Defibrillation** (use an automated external defibrillator for an absent pulse)
- **Deficiency** (assess for sensory or neurologic changes)
- **Deadly bleeding** (assess for massive hemorrhaging and shock)
- **Disability** (assess for spinal cord trauma and injury with movement or sensory deficits) (American College of Surgeons Committee on Trauma, 2017; Thim et al., 2012).

The few seconds taken by the nurse to assess for a patent airway, effective breathing pattern, and effective circulation system are essential. If life-threatening problems are found on assessment, the nurse intervenes with appropriate nursing actions. When initiated immediately, these interventions can positively affect patient outcomes by preventing complications, resolving a deteriorating condition, or saving a life.

Assessment of airway, breathing, and circulation can be done very quickly by observing the patient. Is the patient awake? Moving? Talking? Responding? If there is no problem with airway, breathing, or circulation, a nurse can move on to a more holistic assessment to identify other patient needs. Assessment may include lung sounds, heart sounds, sensorium, emotional status, and psychologic status.

Box 36–4

Examples of Board of Nursing Rules Addressing Prioritization of Care

OHIO Board of Nursing

4723-4-07 Standards for Applying the Nursing Process as a Registered Nurse

(3) Planning

The registered nurse shall, in an accurate and timely manner:

- a. Develop, establish, maintain, or modify the nursing plan of care consistent with current nursing science, including the nursing diagnosis, desired patient outcomes or goals, and nursing interventions; and
- b. Communicate the nursing plan of care and all modifications of the plan to members of the healthcare team;

(d) Implementation:

The registered nurse shall, in an accurate and timely manner implement the current nursing plan of care which may include:

- a. Executing the nursing regimen;
- b. Implementing the current valid order authorized by an individual who is authorized to practice in this state and is

acting within the course of the individual's professional practice;

- c. Providing nursing care commensurate with the documented education, knowledge, skills, and abilities of the registered nurse;
- d. Assisting and collaborating with other healthcare providers in the care of the patient;
- e. Delegating nursing tasks, including medication administration, only in accordance with Chapter 4723-13, 4723-23, 4723-26, or 4723-27 of the Administrative Code.

Tennessee Board of Nursing

1000-01-.14 Standards of Nursing Competence

(1) (a). 2. Establish critical paths and teaching plans based on individual patient's plans of care after prioritizing need upon completion of a comprehensive assessment.

Source: From Tennessee Board of Nursing, 2015. Published by Department of Health Services.

can then use their clinical judgment to make decisions about ranking patient needs as low, medium, and high priorities.

Low Priority

Problems that typically can be resolved easily with minimal interventions and do not cause significant dysfunction are included in the low-priority category. For example, responding to a patient’s request for a midafternoon snack could be delegated to unlicensed assistive personnel.

Medium Priority

These are problems that may result in unhealthy physical or emotional consequences but that are not life threatening. For example, the nurse could ask a patient who exhibits spiritual distress by saying, “God has forgotten about me” if she would like to have a hospital chaplain come visit.

High Priority

This category includes life-threatening problems of airway, breathing, and circulation, or conditions that have a potential to become life threatening within a short amount of time (Tunlind, Granstrom, & Engstrom, 2015). An example of a high-priority intervention is frequent monitoring for unexpected changes in the vital signs and drainage for a patient who has just had a chest tube inserted. See **Table 36–19** » for examples of nursing diagnoses for patients experiencing low-, medium-, and high-priority circumstances.

SAFETY ALERT A survey of perioperative nurses indicated that priority safety issues exist for surgical patients despite increased efforts to reduce surgery-related errors. Perioperative nurses identified wrong site, procedure, and patient issues; medication errors; and pressure injuries from poor positioning, among several other types of errors in surgical cases (Steelman, Graling, & Perkhounkova, 2013). Patient safety is the responsibility of the entire healthcare team. As advocates for patients, nurses should voice their concerns and question and clarify any situation that may compromise patient safety.

TABLE 36–19 Examples of NANDA-I Nursing Diagnoses for Patients Experiencing Low-, Medium-, and High-Priority Circumstances

Low Priority	Medium Priority	High Priority
Readiness for Enhanced Self-Concept	Anxiety	Ineffective Airway Clearance
Fatigue	Diarrhea	Impaired Gas Exchange
Ineffective Health Maintenance	Acute Confusion	Impaired Spontaneous Ventilation
Disturbed Body Image	Disturbed Sleep Pattern	Ineffective Breathing Pattern
Deficient Knowledge	Impaired Bed Mobility	Risk for Bleeding
Powerlessness	Ineffective Coping	Decreased Cardiac Output
Interrupted Family Processes	Self-Care Deficit	Risk for Ineffective Cerebral Tissue Perfusion

Categorizing Priorities

Nurses must set priorities for nursing activities and interventions using assessment data with consideration of the category of the intervention: low, medium, or high priority. In addition, nurses must consider other priorities, including time constraints and the significance of the activities and interventions on patient outcomes. The urgency factor model will help nurses learn how to rank priorities based on time imperatives and severity of patient needs.

Time Constraints

When setting priorities, it is important to remember that some nursing interventions have **time constraints**, or deadlines for completion. One common intervention bound by time constraints is the administration of scheduled medications. Setting priorities for patient care includes planning the day in advance and determining which direct- and indirect-care activities must be completed at expected times (Antinaho et al., 2015). Essential activities not performed by the nurse may result in negative consequences for patients.

The Urgency Factor

Organizing times to provide nursing care is influenced by the urgency factor. The word *urgency* reflects the need to act. **Time priority** means a time constraint is present when completing actions. The **urgency factor** is a way to illustrate how much time can safely lapse before a patient’s health status is compromised. Do all nursing interventions require an immediate action? Can some actions be performed within a short amount of time and others be delayed for a longer period without negative consequences for the patient?

Changes in the patient’s condition, deterioration of status, or the complexities of a patient’s condition can impact the urgency of performing interventions and the order in which the nurse performs those interventions. The urgency factor comprises four levels. These levels progress from not urgent (a low time priority) to high urgency (the highest time priority). The nurse can use the levels of the urgency factor to assist in setting patient-care priorities. By using the levels of urgency, the nurse can identify interventions that need to be completed and the order in which they should be accomplished. See **Figure 36–20** » and the following sections for a diagram and discussion of the urgency levels when setting time priorities.

Nonacute

Interventions with a low urgency factor may be termed *non-acute*. A delay in providing these interventions would not negatively impact patient outcomes. Interventions at this level do not take priority. For example, at the beginning of a shift, the nurse could discuss with a patient scheduling a later time to teach him about changing a dressing.

Acute

Acute interventions are often considered medium priority: There is a low potential for the patient’s condition to become life threatening if these interventions are not accomplished within a short amount of time. Typically, these are actions that nurses are expected to complete to meet identified patient needs. Interventions at this level can be scheduled

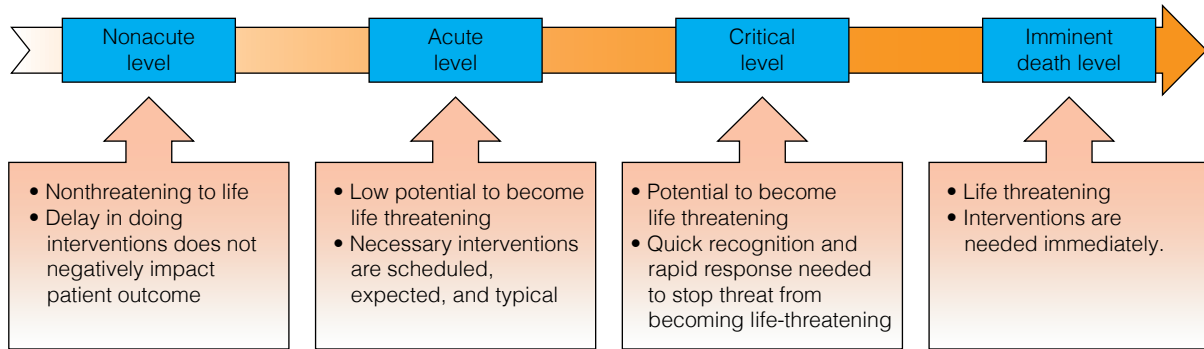

Figure 36-20 » Urgency factor levels for setting time priorities.

during the shift when time constraints of higher priority interventions allow. For example, a nurse can schedule with unlicensed assistive personnel to turn and reposition a patient with impaired bed mobility every 2 hours to prevent skin breakdown.

Critical

This level is considered medium-high urgency: There is an urgent need for the nurse to respond quickly to high-priority physical or psychologic problems within a short amount of time because the potential exists for a patient's condition to become more serious and even life threatening if interventions are delayed. Quick recognition and a rapid response time are necessary to prevent further exacerbation of the patient's problem. For example, a patient develops shortness of breath and air hunger. If the patient does not receive high-flow supplemental oxygen, the patient may develop impaired gas exchange problems that may progress to severe hypoxemia and become life threatening.

Imminent Death

The highest urgency factor is *imminent death*. The time to take action to prevent threat to life takes priority over everything else. When the patient's airway is obstructed, the patient stops breathing, or the patient's heart becomes ineffective in pumping blood through the circulatory system, immediate intervention is necessary to try to save the patient's life. The nurse must act now, STAT, to prevent further deterioration and threat to life.

Of course, there are countless possible life-threatening situations. For example, a patient on suicide precautions is holding a knife against his neck and is threatening to kill himself. Immediate actions must be taken to try and prevent him from harming, and possibly killing, himself. Nurses are always on alert for situations that could result in death for patients. Many of the more common situations, including medication errors, patient identification errors, and other safety issues, are identified in the National Patient Safety Goals (see the module on Safety for additional information).

Ranking Activities

Learning to set priorities is the key to organizing patient care and efficiently using time to provide valued care. Setting priorities leads to providing efficient and effective patient care and can increase patient satisfaction (Papastavrou et al.,

2014). Nurses can set priorities by thinking in terms of these categories: "must do," "should do," and "nice to do."

Priority 1 or Must Do

These activities carry the highest priority for completion, take priority over other interventions, and must be done. For example, suctioning secretions from a tracheostomy tube to keep a patient's airway patent is a *must do* priority.

Priority 2 or Should Do

These activities should be done, but are not essential. These interventions can be accomplished once *must do* activities have been completed or covered. For example, restocking dressing supplies in the room of a patient who needs frequent dressing changes is a *should do* priority.

Priority 3 or Nice to Do

These activities are important to complete, but only after priority 1 and 2 actions have been completed. These actions can be done when time is available, but they are not essential. Nurses should also use their judgment to determine which "should do" and "nice to do" actions may be delegated to unlicensed assistive personnel.

Other category names for level of urgency can be used to rank priorities. See **Table 36-20** » for examples of category names.

Triage

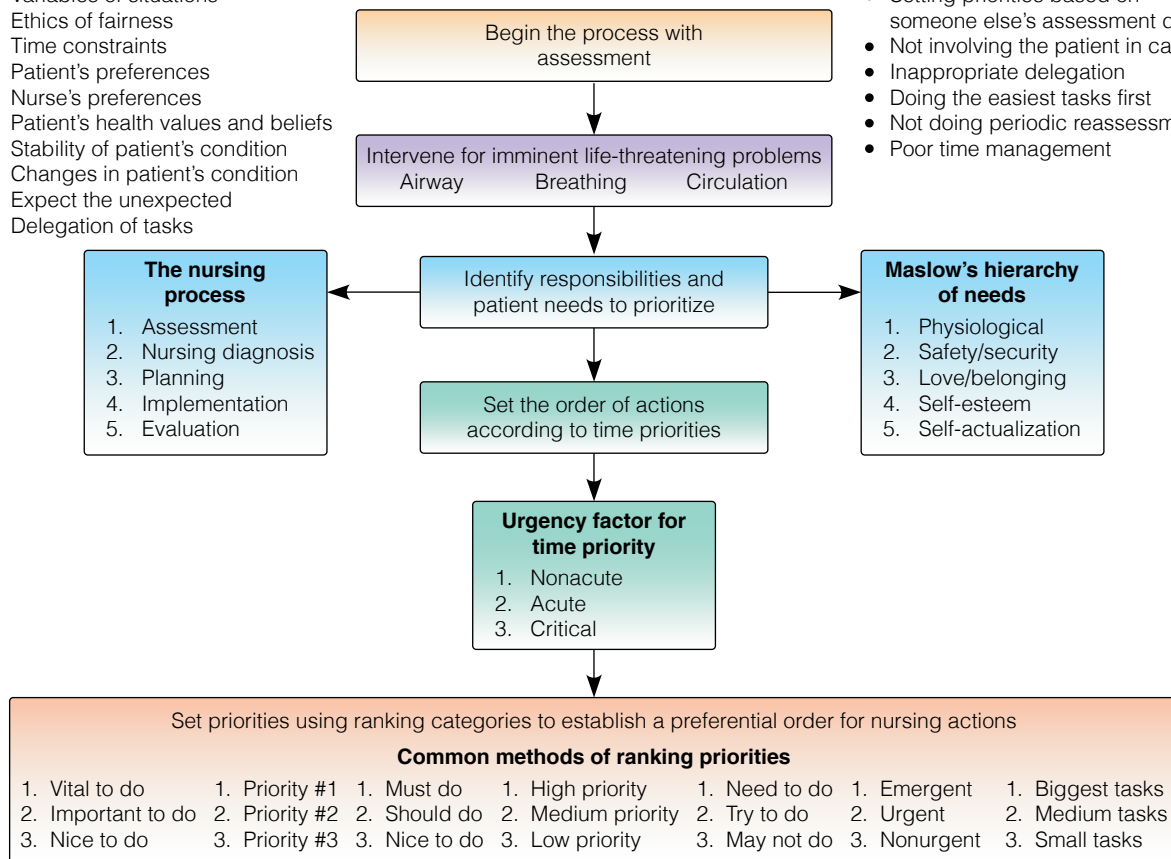

In emergency departments, emergency situations, and pre-hospital care, the process of identifying priorities for implementing care is called **triage**. Triage allows nurses and other healthcare staff to set priorities based on the severity and

TABLE 36-20 Examples of Common Names for Priority Categories

Priority 1	Priority 2	Priority 3
Need to do	Try to do	May not do
Vital to do	Important to do	May not do
Must do	Should do	Nice to do
High priority	Medium priority	Low priority
Most important	Less important	Least important

Factors to consider when setting priorities

- Safety (high priority) for patient and others
- Availability of resources
- Variables of situations
- Ethics of fairness
- Time constraints
- Patient's preferences
- Nurse's preferences
- Patient's health values and beliefs
- Stability of patient's condition
- Changes in patient's condition
- Expect the unexpected
- Delegation of tasks

Prioritizing care process diagram**Pitfalls to avoid when setting priorities**

- Doing before assessing
- Incomplete assessment done
- Error in evaluating patient needs
- Setting priorities based on someone else's assessment data
- Not involving the patient in care
- Inappropriate delegation
- Doing the easiest tasks first
- Not doing periodic reassessment
- Poor time management

Figure 36-21 » Prioritizing care process diagram.

urgency of a patient's illness, injury, and condition (see the module on Healthcare Systems for additional information). Common categories used to set priorities are discussed next.

Emergent (or Immediate)

This category is for life-threatening issues that require prompt treatment and care. Stabilization of the patient's condition is critical. For example, a trauma patient with a blood pressure of 88/56 mmHg and pulse of 108 bpm is emergent.

Urgent (or Delayed)

This category is for serious health conditions in which a delay of treatment and care would not result in life-threatening situations. For example, a patient who complains about having a productive cough for the past 4 days is urgent.

Nonurgent (or Minor)

Patients in this category have minor issues that do not require prompt care. Many of these patients can ambulate and are stable in their conditions. For example, a patient with a splinter in his foot that needs to be removed is nonurgent. Some emergency departments use satellite divisions for patients with nonurgent issues. This allows the main

emergency department to manage patients with emergent and urgent health problems with immediacy while decreasing wait times for nonurgent patients.

See **Figure 36-21** » for a diagram of the prioritization of care process.

Factors to Consider When Prioritizing Care

Prioritization means more than just making decisions about which interventions to do first, second, third, and so forth. The assumption that nurses accomplish all of the things they want or need to do for all of their patients regardless of what order they do them in is no longer true. In some situations, nurses cannot get everything done within an allotted period of time. When nurses experience demands on their services that exceed the time available, they must be able to set priorities of care. Because of this, prioritization sometimes means the most important interventions get done, activities of lesser priority *may* get done, and the least important actions *may not get done at all* because there is insufficient time to complete them.

Prioritizing care in and of itself does not result in nurses being more productive in a given time period. Interventions

take the same amount of time to complete regardless of the order in which they are done. Multitasking and learning to perform certain actions faster may improve effectiveness and efficiency but should never compromise patient safety.

Ethics

A holistic approach to nursing means caring for the physical, psychologic, spiritual, cultural, emotional, and developmental needs of patients. Often, patients have many more needs than nurses are able to meet. The principle of *justice* guides nurses in making decisions about setting priorities (see the module on Ethics). Nurses show *fairness* in treating individuals as equals. The difference among patients is the urgency of their needs; for example, a life-threatening situation will take priority over a psychosocial problem. Decisions are sometimes based on consideration of which actions will result in the best outcomes for the patient (Lachman, 2012).

Safety

Protecting patients and providing them with a safe environment is another aspect of justice. Safety in doing no harm to patients is a professional behavior (see the module on Professional Behaviors for further information). The Institute of Medicine (2011) published a document that emphasized the need to improve safety for patients that led to the National Patient Safety Goals developed by the Joint Commission. For example, safely administering medications to patients is a high priority (see the module on Safety for additional information).

Nurses can be fair in their allocation of time, attention, and skills to ensure patient safety. Unrealistic demands on nurses' physical and emotional abilities may result in nurses minimizing what they can do for their patients and may lead to feelings of dissatisfaction and exhaustion. Nurses' desire to help patients requires an environment that supports the delivery of quality care.

Availability of Resources

Resources are assets that help nurses meet patient needs. Problems arise when necessary resources are not available in the required quantity. Rationing or making decisions about which patients will receive the available resources may require prioritization. For example, a linen cart that has not been replenished leaves everyone without enough towels, washcloths, and gowns for patients. A nurse's creativity and resourcefulness can be valuable in finding solutions, such as borrowing the needed linen from another nursing unit and replenishing it when new linen arrives on the unit.

Nurses should use their time and resources efficiently and minimize activities that detract from patient care. Nurse managers should be made aware of situations that potentially compromise patient care, such as lack of sufficient resources. For example, in the scenario above, the nurse may suggest borrowing linen from another unit to the nurse manager, who then facilitates that arrangement and delegates assistive or supportive personnel to deliver the linen.

Time Management

Time priorities are determined by the urgency of completing interventions for patients. As nurses become proficient,

they develop a sense of how long it takes to complete certain interventions for patients, a skill that helps nurses better manage their time. Part of developing good time management is taking into account specific considerations, such as patient health preferences, changes in patient's condition, unexpected occurrences, and appropriate delegation of tasks.

Multiple Patients

Nurses generally take care of more than one patient at a time. Nurses can identify and plan interventions for all patients based on assessments of assigned individual patient needs, changes in patient status, and complexity of patient problems. Setting priorities is determined by the significance of the interventions for each of the individual patients. Time constraints such as medication administration for multiple patients requires more organization and focus from the nurse in order to complete medication administration within an allotted time frame. The pathophysiology of the individual patients would also require consideration when setting priorities among the assigned patients.

Patient Preferences

Patients are unique individuals who grow and develop as a result of genetic and environmental factors. Although patients share many similarities, such as the need for oxygen, they differ in terms of cultural rituals, spiritual practices, and routines of daily living. Some of these practices have time constraints, such as praying at specific times of day.

Health practices and beliefs of patients may conflict with some physicians' orders. Helping a patient maintain cultural or religious practices without compromising the patient's treatment plan sometimes requires extra effort on the part of the nursing staff. The goal is to strive for a win-win situation by honoring the patient's wishes as much as possible and completing nursing interventions as needed. Working together for a mutually beneficial solution strengthens the patient-nurse relationship.

Prioritizing activities for the day can be done with most patients. The patient's individual preferences and expectations of care can help set time priorities. For example, some patients may prefer to have a shower in the evening instead of the morning. The patient can plan individual activities around nursing actions that are scheduled at certain times. For example, if the patient knows he needs to get medications at 1000 and 1400, he could schedule his walk down the hall at 1100. Activities the patient considers as priorities may differ from those ranked as priorities by the nurse. By assessing for patient preferences, nurses can help strengthen patient participation in and support for the plan of care. Such actions may result in improved patient outcomes, a positive experience for the patient, and greater patient satisfaction.

Change in Patient Condition

Patients need to be monitored continuously for changing circumstances. Assessing patients at 1200 and reporting on them at 1900 without reassessing them means 7 hours have elapsed in which one or more patients have likely experienced a change of status without reassessment by the nurse.

Such infrequent assessments may result in the nurse receiving the shift report receiving inaccurate or incomplete data about the patient.

Nurses depend on other nurses to let them know of problems and changes in their patients. Assessment is an ongoing process to recognize changes and provide appropriate interventions early. When a patient's condition changes or becomes unstable, the earlier it is discovered and addressed, the more quickly nurses and the healthcare team can intervene and prevent further deterioration. A change in patient status may require reevaluating priorities and changing the planned order of interventions. Revising priorities is especially important when planning care for multiple patients.

The Unexpected

Things do not always go as planned. Nurses could plan their workday more efficiently if they could depend on the initial schedule set at the beginning of the shift and follow that plan throughout the day. However, on most days, nurses encounter unexpected events, or **pop-ups**, that require their time and attention and take them away from their plan for the day. For example, a new admission to the unit, a patient whose blood pressure is dropping, or a patient complaining of shortness of breath all take precedence over interventions such as teaching a patient about food choices for a low-salt diet, changing a dressing for a surgical patient, or any number of other nursing interventions. Pop-ups can challenge the time management and organizational skills of the most experienced nurses.

Nurse Self-Care

A nurse's plan for a quick 15-minute break and a 30-minute meal break at the beginning of a shift may sound simple. However, when it is time for nurses to take a break, they often are busy with their patients or other responsibilities; because breaks are not considered a priority, they do not always happen. "I'll go when I finish this" may be a never-ending refrain.

A short time away for self-care can provide quality time to refresh, reenergize, and take care of body functions (drink some water, eat some food, go to the restroom, or do some stretching). A few quiet minutes can help break up the intensity of the work environment and relieve stress for nurses (American Holistic Nurses Association, n.d.).

Delegation

Delegating tasks to other nursing staff, such as LPNs and UAPs, can improve time management. Registered nurses must be aware of the legal responsibilities involved in delegating a task. The task must be within the scope of practice for the nursing staff member to whom the task has been delegated. The nurse who delegates the task must evaluate the task upon its completion (Yoon, Kim, & Shin, 2016). See the exemplar on Delegation in the module on Managing Care for more information.

Delegation between the RN and UAPs requires mutual trust and demonstrates the RN's confidence in staff members' abilities to assist in patient care. New RNs often do not delegate tasks because of fear of negative occurrences for which they will be responsible. Also, they are often unsure of which tasks may be delegated to UAPs, and they have yet

to develop the skills to determine trustworthiness in UAP staff members (Ekstrom & Idvall, 2013; Yoon et al., 2016). Furthermore, novice nurses often fail to see themselves as leaders and fear being perceived as assertive by UAPs (Ekstrom & Idvall, 2013). Role-playing during orientation and preceptorship and discussions with a mentor may help the new nurse recognize when it is appropriate to delegate lower-level priorities to UAPs and that leadership is an inherent role of registered nurses.

Pitfalls of Prioritization

Nurses should learn to avoid pitfalls when prioritizing care. A **pitfall** is an unforeseen situation that often harbors consequences for nurses and can result in patient harm. Although nurses may not know all of the possible pitfalls, there are some pitfalls they can learn to recognize and avoid. When nurses follow ethical practices, use available resources, know the health concerns of their patients, have a sense about patient priorities, prioritize care appropriately, and use questions from clinical decision-making models, they can avoid many pitfalls. Common pitfalls are described in the following sections.

Prioritizing Without Assessment

Nurses need as much information as they can gather about their assigned patients, especially when they are assigned more than one patient. When providing care to multiple patients, nurses must consider interventions for all patients separately and set priorities. Without assessment, the first step in the prioritization process, nurses may forget important interventions or provide interventions based on old data. Patients may sustain severe consequences as a result.

Incomplete Assessment

Part of knowing how to do an assessment is learning what information is required to set priorities for patient care. Accurate and timely information about patient status, resources, available nursing staff, time constraints, and complexity of interventions is needed to prioritize care. If any of these are not assessed first, nurses will fail to include important and necessary information when setting priorities.

Relying Solely on Another's Assessment

Obtaining assessment data from another nurse, such as during shift report, can provide insight and give a picture of a patient's status during the previous shift. However, using only this information to set priorities, without also performing one's own assessment, may negatively affect patient outcomes.

Failing to Do Periodic Reassessments

Reassessment allows the nurse to adjust the time and order of actions to support completing interventions and activities on time and in order of importance. Sometimes the unexpected happens, taking the nurse in another direction and interrupting planned activities. Examples of these situations include a change in a patient's condition, arrival of a new patient who needs to be admitted to the unit, and a request from a relative or visitor to speak with the nurse. Periodic reassessments give the nurse a sense of the time available to perform actions, determine which actions still need to be done, and when to perform these actions throughout the shift.

Box 36–5

Time Management Suggestions

At home, the night before your shift:

1. Make a list of scheduled medication administration times (i.e., 0730, 0800, 1000, 1200, 1400, and 1600).
2. Under each time, list expected patient interventions that will happen close to the times (i.e., meals, safety checks, IV checks, pain management checks, physician rounds, AM care, and documentation). This is the blueprint to follow for managing your time.
3. If you know of any procedures you may need to do the next day, review and visualize how to do them so you will be prepared and not use time the next day to refresh how to perform the procedure (e.g., giving an IV piggyback medication, inserting an indwelling urinary catheter).

At the beginning of your shift:

1. Eat something before arriving; arrive early to put your things away.
2. Listen to the change-of-shift report to get a sense of how your day may go (acuity of patients assigned, problems you may have, patients who may require more time, and so on).

3. Add any time constraint activities to your blueprint (e.g., a meeting you need to attend).
4. Make safety check rounds on your patients to assess for additional information.
5. Begin setting priorities for patient care. Remember to include the urgency factor for time priorities. Delegate tasks to nursing staff working with you as appropriate. Remember to perform actions you've designated as priorities or difficult actions early and check them off of your to-do list.
6. Become more aware of time by checking your watch every couple of hours to get a sense of where you are with completing your activities.
7. Keep a notepad handy in a pocket to make notes about everything you do or want to remember later. This will increase your accuracy and relieve you from relying on memory. These notes will be useful for documentation time or for change of shift (Froedge, 2013).
8. Reprioritize your time as needed when pop-ups or unplanned events occur.
9. Check your progress in completing your to-do list throughout the shift. Reprioritize activities as needed.
10. Celebrate your success as you complete priority interventions.

Poor Time Management

Time management can be difficult for nurses to master, especially for those who do not check their watches every couple of hours to sense where they are in terms of accomplishing patient-care activities. Nurses may find that some actions have taken longer than expected to complete, while others have taken less time. Some actions have time constraints that may not be altered. Proficient time management ensures that priority tasks are accomplished in a timely manner and that the nurse remains productive during the shift. See **Box 36–5** » for suggestions on managing time.

SAFETY ALERT Nurses are aware of healthcare organizations' policies and procedures related to quality nursing care, patient safety, and general institutional safety guidelines, three essential factors in prioritizing patient care. However, a recent study found inconsistency between nurses' knowledge of policies and procedures regarding safety, and compliance with quality and safety indicators and safety implementation. The researchers state that factors such as improving nurse-to-patient ratio, increasing nurses' participation in clinical decision making, and promoting champions for nursing units, among other recommendations, may help close this gap (Alam & Alabdulaali, 2016). These factors may also help nurses avoid pitfalls that occur because of short staffing or, in some cases, lack of participation in nursing governance.

Patient care is individualized even when addressing routine tasks. When working with children and with older adults, more time may be needed for discussions, answering questions, and teaching, based on the patient's developmental stage and cognitive ability. In addition, during the course of the work shift, the nurse can expect to encounter family members and caregivers, in person and by phone, who will also require time as they present questions about

the state of the patient's health. Nurses often forget to include these occurrences when considering their plan for the day. By recognizing that interactions with patients and families will take time away from tasks, the nurse is able to plan the workday with consideration for such encounters. Patients and families must perceive that the nurse is fully engaged in responding to their needs: they should not feel rushed or hurried. Both patients and families recognize meaningful encounters and nursing attention as signs of quality care.

Not Involving Patients in Their Care

Nurses assess and determine patient needs when setting priorities. Nurses are also accountable for planning and carrying out interventions, but it is a mistake not to include the patient in planning his or her care. Patients have preferences in how they do things, when they want things to happen, and what they want to do. Preferences may be a result of culture, family influences, spirituality, or heritage. Asking patients about their needs is a way to recognize their individuality and deliver patient-centered nursing care. Observing patient behaviors can also provide the nurse with cues about time and order of patients' preferences.

Inappropriate Delegation

Nurses must follow certain rules when delegating tasks to others (see the module on Managing Care for further information). Other nursing staff, LPNs, and UAPs can assist in completing tasks for patients if the tasks are within the scope of practice found in their state's nurse practice act. Transferring responsibility for a task to an LPN or UAP does not remove accountability for the outcome from the registered nurse. Inappropriate delegation may result in the RN having to repeat an intervention or may even result in harm to the

patient. Inappropriate delegation can have immediate ramifications for patient care.

Doing the Easiest Tasks First

Setting priorities means determining those actions that are more important than others and ordering actions based on their priority. Nurses become competent in the process of

prioritizing through practice. Completing important, necessary, and sometimes complicated nursing tasks and interventions before easier, less complicated ones makes good, professional common sense. Positive patient outcomes occur when nurses provide intentionally planned care services to meet patients' needs.

REVIEW Prioritizing Care

RELATE Link the Concepts and Exemplars

Linking the exemplar of prioritizing care with the concept of clinical decision making:

1. What are some commonalities between these two nursing processes?

Linking the exemplar of prioritizing care with the concept of safety:

2. Why is safety a high priority for patients who have *Risk for . . .* nursing diagnoses?

Linking the exemplar of prioritizing care with the concept of professionalism:

3. What aspects of setting priorities for care are professional behaviors for nurses?

Linking the exemplar of prioritizing care with the concept of managing care:

4. Name some ways setting priorities for care contributes to improved management of care.

REFLECT Apply Your Knowledge

You have been assigned to take care of Mr. J. Rodriguez, a 48-year-old male patient, during clinical from 0645 to 1300. This patient was admitted to the medical unit yesterday with bilateral pneumonia. He has a history of shortness of breath and exertional dyspnea for the past week. He states he has had a productive cough for the past 4 days, with green, foul-smelling thick sputum. He complains of chest pain when he has to cough. His appetite is diminished and he is not drinking very much because he says he is too tired. He also states he was not able to go to work the 2 days before he was admitted to the hospital. Mr. Rodriguez lives with his wife and four children. His wife speaks very little English. His last set of vital signs were temperature 102.2°F (39°C), pulse 98 bpm, respirations 22/min; blood pressure 134/86 mmHg. He is friendly, quiet, and wants to get better. He is in no distress at this time.

Physician orders include:

- IV D₅ 1/2NS with 20 mEq KCl at 100 mL/hr
- Rocephin 1 gram IV piggyback every 12 hours
- I&O every shift
- Vital signs every 4 hours, including pulse oximetry
- Out of bed to chair with assistance
- Regular diet, encourage fluids

- Use an incentive spirometer 10 times every hour while awake
- Oxygen via nasal cannula at 2 LPM oxygen.

Nursing interventions include:

- Assisting with bath and morning care as needed
- Changing bed linens on patient's bed
- Administering medications at 0800, 1000, 1200
- Assisting with breakfast as needed at 0800
- Assisting with lunch as needed at 1230
- Doing a 60-second patient safety check every 2 hours
- Doing a complete assessment on the patient early morning
- Reassessing the patient's condition every 4 hours
- Doing vital signs at 0800 and 1200
- Assisting the patient with incentive spirometry during morning hours
- Encouraging the patient to drink fluids
- Checking for new physician orders
- Checking for diagnostic test results
- Listening to report from previous shift nurse
- Assisting patient in menu selection for tomorrow's meals
- Teaching the patient how to splint his chest with a pillow when he needs to cough to prevent chest muscles from hurting with coughing
- Documenting in patient's electronic medical record throughout the day
- Checking the patient's IV every 4 hours
- Providing fresh ice water in the patient's water pitcher
- Measuring and tallying the I&O for the patient during the shift
- Assisting the patient to get up to the chair in the morning and again in the afternoon.

List any additional interventions you would want to do with this patient:

- 1.
- 2.
- 3.

Decide the priority of each of the above nursing interventions, both those listed and your own. Indicate your priority choice beside each one by writing a "1" for a high priority, a "2" for a medium priority, and a "3" for a low priority. Now decide which actions can be delegated to a UAP to assist in completing them all. Write a "D" beside the interventions that can be appropriately delegated to a UAP.

Module 37

Collaboration

Module Outline and Learning Outcomes

The Concept of Collaboration

The Nurse as Collaborator

37.1 Describe the nurse's role as a collaborative member of the healthcare team.

Concepts Related to Collaboration

37.2 Describe the relationship between collaboration and selected other concepts and implications for nursing care.

Competencies Basic to Collaboration

37.3 Identify competencies necessary for successful collaboration.

Interprofessional Collaborative Practice

37.4 Summarize the benefits and nature of interprofessional collaborative practice.

Conflict Prevention and Management

37.5 Analyze aspects of conflict prevention and management.

Incivility in the Workplace

37.6 Describe the effects of incivility in the workplace.

>> The Concept of Collaboration

Concept Key Terms

Collaboration, 2543	Covert conflict, 2550	Intergroup conflict, 2550	Interprofessional, 2543	Mutual respect, 2547
Conflict, 2550	Horizontal violence	Interorganizational	Intrapersonal	Overt conflict, 2550
Conflict	(HV), 2554	conflict, 2550	conflict, 2550	Verbal abuse, 2554
conflict competence, 2551	Interdisciplinary, 2543	Interpersonal conflict, 2550	Mindsight, 2552	Workplace bullying, 2554

The nature of healthcare today is so complex that it is impossible for any single provider or professional to provide high-quality patient care without working with others. The best care is delivered in a collaborative environment with all members of the healthcare team working to improve patient health outcomes. **Collaboration** is defined as two or more individuals working toward a common goal by combining their skills, knowledge, and resources while avoiding duplication of effort. In a healthcare environment, the common goal of each collaborative team is to improve patient outcomes, whether the patient is an individual, a group, or a community.

The American Nurses Association (ANA) Standards of Professional Nursing Practice recognize collaboration as a key component of nursing practice. Standard 10 of the ANA Standards of Professional Nursing Practice outlines specific competencies related to the nurse's role in collaboration (ANA, 2015) (**Box 37-1** >>). Cronenwett and coworkers (2007), as part of the QSEN (Quality and Safety Education for Nurses) project, identified six competencies necessary to improve the quality and safety of the patient care environment. Teamwork

and collaboration were identified as two of the major competencies necessary for achieving quality patient care. Virginia Henderson (1991), one of the pioneers of professional nursing, defined collaborative care as "a partnership relationship between doctors, nurses, and other healthcare providers with patients and their families" (p. 44). Mutual respect and a true sharing of both power and control are essential elements. Ideally, collaboration becomes a dynamic, interactive process in which patients (individuals, groups, or communities) work together with physicians, nurses, and other healthcare providers to meet their health objectives.

There has been an increased emphasis in the nursing community on the value of interprofessional collaboration and practice as a means to improve patient outcomes (National League for Nursing [NLN], 2015). The term **interprofessional** usually refers to professionals from various disciplines, whereas the term **interdisciplinary** is often used to denote that paraprofessionals or others (such as patients or family members) are also included. For the purposes of this module, we use the term *interprofessional* to refer to professionals from various disciplines along with support

Box 37–1

QSEN: Teamwork and Collaboration

According to QSEN, nurses should be able to function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care. The knowledge (K), skills (S), and attitudes (A) necessary to do such include:

- **(K)** Describe one's personal strengths, limitations, and values in functioning as a member of a team. **(S)** Demonstrate an awareness of personal strengths and limitations; initiate a plan for self-development as a team member and, act with integrity, consistency and respect for differing views. **(A)** Acknowledge your potential to be a contributing team member while appreciating the importance of collaboration.
- **(K)** Describe the scope of practice and roles of other health team members, the strategies for identifying and managing overlaps in team member roles, and recognize the contributions of other team members in helping patients and families to achieve goals. This can be achieved by **(S)** functioning within your scope of

Source: Based on Cronenwett, L., Sherwood, G., Barnsteiner, J., Disch, J., Johnson, J., Mitchell, P., & Warren, J. (2007). Quality and safety education for nurses. *Nursing Outlook*, 55(3), 122–131.

practice, assuming the role of team member or leader as appropriate, requesting help when needed, clarifying roles, and integrating the contributions of others in a **(A)** respectful manner.

- **(K)** Analyze differences in communication style and understand the impact of your own communication style on others by **(S)** communicating with and soliciting input from team members, and initiating actions to resolve conflict by **(A)** actively participating in the resolution process.
- **(K)** Describe the impact of team functioning on patient safety and quality care and explain how levels of authority have the potential to affect teamwork. **(S)** Follow best practice to minimize risks associated with handoffs and **(A)** acknowledge that care transition is risky.
- **(K)** Identify system barriers and facilitators of effective team functioning and examine strategies for improving systems to support team performance by **(S)** participating in designing systems that support teamwork and **(A)** valuing the influence of system solutions in achieving effective team functioning.

staff, the patient, and family members—anyone who is working together for the benefit of the patient.

Successful collaboration requires that nurses develop skills in communication and teamwork, value the roles and responsibilities of other team members, and work to establish a climate of mutual respect. Successful interprofessional education and practice depends on healthcare professionals working in teams so as to provide safe, quality care (NLN, 2016).

The Nurse as Collaborator

Collaboration may occur between nurses, between healthcare providers and patients, and between healthcare providers from different professional backgrounds (**Figure 37–1** »). According to the ANA (2015), collaborative interprofessional teams recognize each individual profession's value

Source: Jose Luis Pelaez Inc./Blend Images/Getty Images.

Figure 37–1 » The healthcare team works together to communicate concerns and mutually problem solve.

and contributions in an atmosphere of mutual trust and respect through open discussion and shared decision making (p. 8). In addition to collaborating with other professionals to provide individual patient care, nurses may also be involved in collaborating to develop community initiatives, write or revise legislation, or conduct health-related research. **Table 37–1** » lists a number of professionals who may serve as members of an interprofessional healthcare team and their respective roles.

To fulfill a collaborative role, nurses need to assume accountability and increased authority in their practice areas. Continuing education in role exploration, communication, group work, and other areas helps members of the healthcare team understand the collaborative nature of their roles, specific contributions of each professional member, and the importance of working together. Each professional needs to understand how an integrated delivery system centers on the patient's healthcare needs rather than on the particular care given by any one group. **Box 37–2** » describes selected aspects of the nurse's role as a collaborator.

Concepts Related to Collaboration

Effective collaboration affects healthcare positively on every level. At the organizational level, collaboration leads to increased efficiency and greater cost effectiveness. For patients, collaboration among members of the healthcare team promotes safety, resulting in decreased morbidity and mortality rates. Patients who are involved in the collaborative process report an increased sense of autonomy, which leads to greater overall satisfaction with care. Nurses who effectively collaborate report an increased sense of perceived autonomy and professionalism, along with greater job satisfaction. Some, but not all, of the concepts that are integral to collaboration are shown in the Concepts Related to Collaboration feature. They are presented in alphabetical order.

TABLE 37–1 Collaborative Members of the Healthcare Team

Healthcare Professional	Role
Nurse	The role of the nurse varies with the needs of the patient, the nurse's credentials, and the type of employment setting. A registered nurse (RN) assesses a patient's health status, identifies health problems, and develops and coordinates care. A licensed vocational nurse (LVN), in some states known as a licensed practical nurse (LPN), provides direct patient care under the direction of a registered nurse, physician, or other licensed practitioner. A Nurse Practitioner (NP) has a graduate degree and is qualified to treat certain medical conditions.
Unlicensed assistive personnel	Unlicensed assistive personnel (UAP) are healthcare staff who assume delegated aspects of basic patient care. These tasks include bathing, assisting with feeding, and collecting specimens. UAP titles include certified nurse assistants, hospital attendants, nurse technicians, patient care technicians, and orderlies. Some of these categories of provider may have standardized education and job duties (e.g., certified nurse assistants), while others do not. The parameters regarding nurse delegation to UAP are delineated by the state Boards of Nursing and statutes contained in state administrative codes.
Complementary healthcare providers	Non-mainstream practice used along with conventional medicine is considered as complementary. Examples of complementary practice groups include: chiropractors, herbalists, acupuncturists, massage therapists, reflexologists, holistic health healers, and other healthcare providers. These professionals, when used in conjunction with providers of allopathic or Western medicine, are considered to be complementary providers.
Case manager	The case manager's role is to ensure that patients receive fiscally sound, appropriate care in the best setting. This role is often filled by the member of the healthcare team who is most involved in the patient's care. Depending on the nature of the patient's concerns, the case manager may be a nurse, a social worker, or any other member of the healthcare team.
Dentist	Dentists diagnose and treat dental problems. Dentists are also actively involved in preventive measures to maintain healthy oral structures (e.g., teeth and gums). Many hospitals, especially long-term care facilities, have dentists on staff.
Dietitian or nutritionist	A dietitian, often a registered dietitian (RD), has special knowledge about the diets required to maintain health and to treat disease. Dietitians in hospitals generally are concerned with therapeutic diets, may design special diets to meet the nutritional needs of individual patients, and supervise the preparation of meals to ensure that patients receive the proper diet. A nutritionist is an individual who has special knowledge about nutrition and food. The nutritionist in a community setting recommends healthy diets and gives broad advisory services about the purchase and preparation of foods. Community nutritionists often function at the primary preventive level. They promote health and prevent disease, for example, by advising families about balanced diets for growing children and pregnant women.
Information technology expert	In healthcare organizations, an information technology (IT) expert offers knowledge and expertise in the ever-expanding field of computer science in application to health and health systems. The IT expert's knowledge base includes installing and repairing computer hardware, maintaining databases, and educating users about the use of computer applications, such as electronic health records (EHRs), and communication processes such as telemedicine.
Occupational therapist	An occupational therapist (OT) assists patients with impaired function to gain the skills to perform activities of daily living. For example, an occupational therapist might teach a man with severe arthritis in his arms and hands how to adjust his kitchen utensils so that he can continue to cook. The occupational therapist teaches skills that are therapeutic and at the same time provide some fulfillment. For example, weaving is a recreational activity but also exercises the arthritic man's arms and hands. Occupational therapists also perform developmental assessments and provide therapy for patients of all ages during recovery from or adaptation to a variety of alterations, including traumatic injuries, medical conditions that affect cognition, congenital disorders, and alterations related to prematurity.
Paramedical technologist	Laboratory technologists, radiologic technologists, and nuclear medicine technologists are just three kinds of paramedical technologists in the expanding field of medical technology. <i>Paramedical</i> means having some connection with medicine. Laboratory technologists, for example, examine specimens such as urine, feces, blood, and discharges from wounds to provide exact information that facilitates the medical diagnosis and the prescription of a therapeutic regimen.
Pharmacist	A pharmacist prepares and dispenses medications in hospital and community settings. The role of the pharmacist in monitoring and evaluating the actions and effects of medications on patients is becoming increasingly prominent. A clinical pharmacist is a specialist who guides physicians in prescribing medications.
Physical therapist	The licensed physical therapist (PT) assists patients with musculoskeletal problems. Physical therapists treat movement dysfunctions by means of heat, water, exercise, massage, and electric current. The physical therapist's functions include assessing patient mobility and strength, providing therapeutic measures (e.g., exercises and heat applications to improve mobility and strength), and teaching new skills (e.g., how to walk with an artificial leg). Physical therapists work in hospitals, offices, and in patients' homes.
Physician	The physician is responsible for medical diagnosis and for determining the therapy required by an individual who has a disease or injury. The physician's role has traditionally been the treatment of disease and trauma (injury); however, many physicians are now including health promotion and disease prevention in their practice. Some physicians are general practitioners (also known as primary care or family practitioners); others are specialists, such as dermatologists, neurologists, oncologists, orthopedists, pediatricians, psychiatrists, radiologists, or surgeons—to name a few.
Physician assistant	Physician assistants (PAs) perform certain tasks under the direction of a physician. They diagnose and treat certain diseases, conditions, and injuries. In many states, nurses are not legally permitted to follow a PA's orders unless the orders are cosigned by a physician.
Respiratory therapist	A respiratory therapist is skilled in therapeutic measures used in the care of patients with respiratory problems. These therapists are knowledgeable about oxygen therapy devices, intermittent positive pressure breathing respirators, artificial mechanical ventilators, and accessory devices used in inhalation therapy. Respiratory therapists administer many of the pulmonary function tests.
Social worker	A social worker counsels patients and their support people regarding problems, such as finances, marital difficulties, and adoption of children. It is not unusual for health problems to produce problems in day-to-day living and vice versa. For example, an older woman who lives alone and has a stroke resulting in impaired walking may find it impossible to continue to live in her third-floor apartment. Finding a more suitable living arrangement can be the responsibility of the social worker if the patient has no support network in place.

Box 37–2

The Nurse as a Collaborator

With Patients

- Acknowledges, supports, and encourages patients' active involvement in healthcare decisions.
- Encourages patient autonomy and equal position with other members of the healthcare team.
- Helps patients set mutually agreed-on goals and objectives for healthcare.
- Provides patients with consultation in a collaborative fashion.

With Peers

- Shares personal expertise with other nurses and elicits the expertise of others to ensure high-quality patient care.
- Develops a sense of trust and mutual respect with peers who value each member's unique contributions.

With Other Healthcare Professionals

- Recognizes the contribution that each member of the interprofessional team can make by virtue of his or her expertise.
- Listens to each individual's viewpoints.

- Shares healthcare responsibilities with other members of the team in order to explore care options, set realistic and attainable goals, and make decisions about the plan of care with patients and their families.
- Participates in collaborative interprofessional research to increase knowledge of a clinical problem or situation.

With Professional Nursing Organizations

- Seeks opportunities to collaborate with and within professional organizations.
- Serves on committees in state (or provincial), national, and international nursing organizations or specialty groups.
- Supports professional organizations in political action to create solutions for professional and healthcare concerns.

With Legislators

- Offers expert opinions on legislative initiatives related to healthcare.
- Collaborates with other healthcare providers and consumers on healthcare legislation in order to best serve the needs of the public.

Competencies Basic to Collaboration

Key features necessary for collaboration include mutual respect, trust, effective communication skills, giving and receiving feedback, decision making, and conflict management (Masters, 2013).

Communication Skills

Collaborating to solve complex problems requires effective communication skills. This is supported by the fact that miscommunication among providers has been identified as one of the most frequent root causes of sentinel events (unintended events that cause serious physical or psychologic injury or death) (The Joint Commission, 2012). The typical

Concepts Related to Collaboration

CONCEPT	RELATIONSHIP TO COLLABORATION	NURSING IMPLICATIONS
Health Policy	↑ job satisfaction	<ul style="list-style-type: none"> ■ Acknowledgment by senior leader to support new approaches in workforce development and innovations that improve job working environments and increase job satisfaction.
Healthcare Systems	↑ collaboration among healthcare team members → ↓ duplication of patient services and ↓ healthcare costs	<ul style="list-style-type: none"> ■ Support and promote collaboration among healthcare team members. ■ Apply principles of effective collaboration, including principles that facilitate clear communication. ■ Be aware of the patient's plan of care, including ordered tests and diagnostics, and question apparent duplications using a polite, professional approach.
Professionalism	↑ nurse–physician collaboration → ↑ perceived professional autonomy → ↑ nursing professionalism	<ul style="list-style-type: none"> ■ Recognize the impact of collaboration on job satisfaction in nursing. ■ Effectively apply principles of collaboration to promote collaborative nurse–physician relationships.
Quality Improvement	↑ situational awareness ↑ teamwork among healthcare team members	<ul style="list-style-type: none"> ■ Effectively identify threats to patient safety through open communication, identification of purpose and skill, and established plan of action.
Safety	↑ collaboration among healthcare team members → ↓ patient morbidity and ↓ patient mortality rates	<ul style="list-style-type: none"> ■ Support and promote collaboration among healthcare team members. ■ Support the scheduling of interprofessional team meetings and attend all scheduled meetings. ■ Educate healthcare team members about the safety-related benefits of collaboration.

patient environment is fraught with interruptions, distractions, conflicting goals, anxieties, and stressors that often hamper the best intentions. Even the most well-intended fundamental statement can be misinterpreted or misunderstood and compound the problem (Ruben, 2016).

True collaboration requires skilled communication and mutual respect in order to achieve desired patient outcomes. Expert collaborators hold themselves and each other accountable for serving as patient advocates, acting as skilled negotiators, and acting to resolve conflict. Instead of focusing on distinctions among members, each team must keep firmly in mind its common purpose, that of meeting the needs of the patient.

Each member of the healthcare team should be sensitive to differences among communication styles and the effects that her own style has on successful collaboration (see the module on Communication for information about communication styles). Team-centered communication, as opposed to status-based communication, demonstrates appreciation for member contributions. Team-centered approaches focus on the “we” — the work “we will do for this patient” — versus one-sided commands such as “give this, do that” statements that do not invite dialogue and do not promote collaboration. Effective communication can occur only if every team member is committed to understanding each member’s professional role and appreciating each member as an individual. Team-centered communication focuses on shared responsibilities (Matzke et al., 2014). Identifying and preventing any potential cultural or language barriers also is critical to ensuring successful collaboration (see Focus on Diversity and Culture).

For all patients, communication is a key component (or competency) of effective nursing care and a means for

promoting nurse–patient collaboration. Miscommunication among healthcare providers can lead to serious consequences. A lack of collaboration skills can impede safe practice. Acknowledging alternative perspectives, articulating one’s own viewpoint, and engaging in mutual give and take are necessary qualities for effective collaboration. Using an attentive style of communication that encompasses active listening versus a dominant, take-charge, or contentious and argumentative style helps to remove the barriers that impede effective communication and collaboration.

Mutual Respect and Trust

Mutual respect occurs when two or more individuals show or feel honor or esteem toward one another. Trust occurs when an individual is confident in the actions of another individual. Both mutual respect and trust imply a shared process and outcome. They must be expressed both verbally and nonverbally. Sometimes professionals may *verbalize* respect or trust of others but *demonstrate* a lack of trust and respect through their actions. The healthcare system itself has not always created an environment that promotes respect or trust of the various healthcare providers. Although progress has been made toward creating more trusting relationships, past attitudes may continue to impede efforts toward collaborative practice (see the Evidence-Based Practice feature). Magnet hospitals are an example of successful efforts by healthcare organizations to foster respect among professionals. Placing the head of the nursing department (previously known as the director of nursing) on an equal managerial level with the chief of physicians (usually called the chief medical officer) has been found to improve mutual respect between physicians and nurses, thereby improving their relationships.

Decision Making

Collaboration involves shared responsibility for the outcome. To create a solution, the team must follow each step of the decision-making process, beginning with a clear definition of the problem (see the module on Clinical Decision Making). Team decision making must be directed at the objectives of the specific effort. Demonstration of mutual respect and timely, effective feedback facilitate the decision-making process.

Sound decision making regarding patient care requires that the healthcare team focus on the patient’s priority needs and organize interventions accordingly. The discipline best able to address the patient’s needs is identified, given priority in planning, and held responsible for providing its interventions in a timely manner. For example, when social needs (such as loss of a home or job) interfere with the patient’s ability to respond to therapy, the team may agree that the social worker needs to intervene to help the patient resolve his social needs before starting therapy. Nurses, by the nature of their holistic practice, are often able to help the team identify priorities and areas requiring further attention. Ideally, the collaborative team will ensure that the patient is part of the decision-making process, even if the patient is not able to be present. Decision-making processes are discussed in greater detail in the module on Clinical Decision Making.

Focus on Diversity and Culture Collaboration and the Dangers of Language

Ineffective management of cultural language barriers can impede collaboration and negatively impact medical and nursing diagnoses, as well as patient outcomes (Garcia & Duckett, 2009). Nurses should use evidence-based practice interventions that have been shown to be the most effective for culturally diverse populations. Universal guidelines for implementing culturally competent care require that nurses have an awareness of the patient’s values, learning preferences, and behavior and work to include culturally appropriate verbal and nonverbal communication skills when working with patients. Nonverbal communication skills include an understanding of the patient’s perceptions of space, silence, touch, modesty, and preferences for provider gender. Acting as a true advocate, the nurse must do everything possible to ensure competent, quality care, including the use of an interpreter and selective print media appropriate for the patient’s cultural values and age (Douglas et al., 2014). In addition, providing culturally competent care is a priority of The Joint Commission (2016), which recommends that hospitals provide staff training on the cultural health beliefs and practices and, in doing so, support systems that allow for effective communication and cultural competence.

See the module on Culture and Diversity for more information on providing culturally competent care.

Evidence-Based Practice

Overcoming Barriers: The Benefits of Nurse–Physician Collaboration

Problem

Despite research-based evidence that supports the benefits of effective collaboration between nurses and physicians, barriers to this process—several of which relate to the relationship between the nurse and the physician—remain intact.

Evidence

A review of the literature from 2009 to 2015 indicates that barriers in nurse–physician communication discourage collaboration (Fewster-Thuente, 2015). Reported obstructive behaviors are hierarchical and/or patriarchal nurse–physician relationships and misperceptions about how collaboration should occur. A culture of safety for patients depends on collaborative communication. Although nursing education programs have promoted a shift in the nurse’s perception of the nurse–physician relationship from subservient–superior to collegial, some physicians at present view this collegial relationship as undermining their leadership and authority (Schneider, 2012).

Despite the barriers to nurse–physician collaboration, research strongly supports this practice. Interprofessional collaboration between physicians and nurses is linked to decreased patient morbidity and mortality (Schneider, 2012). Along with enhancing overall patient safety, benefits of effective collaboration between physicians and nurses also include a decreased risk for medication-related errors and improved cost containment (Nair et al., 2012).

Implications

Overcoming the barriers to effective collaboration is imperative. Some suggestions for promoting change are employing interprofessional rounding on patients during which each health team member has an opportunity to share pertinent information and suggestions for patient care; interprofessional simulations, and inter- and intraprofessional coursework. For the benefit of the patient, the healthcare system, and the professionals caring for the patient, nurses should support and promote the development of collaborative relationships with physicians, as well as with all other members of the healthcare team.

Critical Thinking Application

Development of a collaborative relationship requires mutual trust and respect, demonstrated efficacy with conflict resolution, clear methods of communication, and professionalism during all negotiation processes (Schneider, 2012). The common goal of providing the best care possible for the patient should be the starting point of all discussions and remain as the focal point throughout patient care. The expertise of each collaborator needs to be shared and appreciated; the physician or advanced practice nurse for the diagnostic information, the nurse for the patient- and family-specific knowledge, and the allied health team members (e.g., PT, OT, social work) for their skill and capability in condition-specific treatment and follow-up (Fewster-Thuente, 2015).

Clinical Example A

Bill Hainsley, 67 years old, will be transferring from the acute care hospital to a nearby rehabilitation facility following his knee replacement. Although Mr. Hainsley believes that he is perfectly capable of managing his rehabilitation at home, his wife is concerned about her ability to help him navigate their two-story house, which has only a small half-bath on the first floor. Mr. Hainsley is worried about the cost of going to a rehabilitation facility and is not sure how much, if any, of this will be covered by his insurance because he is retired. The RN case manager has decided to schedule a meeting with the Hainsleys that also includes the physical therapist and social worker. The nurse would like for the physical therapist to provide Mr. Hainsley and his wife with a description of the anticipated exercise protocol as well as some idea of the expected time frame for physical improvement and safe return to home. The nurse has included the social worker for help in addressing Mr. Hainsley’s concern about what his insurance might cover, what Medicare will cover, and any anticipated out-of-pocket costs. The nurse acts as a facilitator in ensuring that all of Mr. and Mrs. Hainsley’s fears are addressed before they make a decision about discharge. In addition, the nurse documents in the chart that the meeting occurred, who was involved, and the final decision by the patient about his discharge.

Critical Thinking Questions

1. Is there anyone else that the RN case manager should have included in this collaborative meeting with the patient and, if so, who and for what reason?
2. What other approach might the nurse case manager have used if the physical therapist and social worker were not available?
3. What approach can be used if Mr. Hainsley chooses to go home rather than to a rehabilitation facility?

Interprofessional Collaborative Practice

Many healthcare professionals believe that an interprofessional, collaborative framework can manage costs, enhance quality, and increase patient satisfaction with care. Interprofessional collaborative practice models attempt to achieve the following objectives:

- Provide patient-directed and patient-centered care using an interprofessional, integrated, participative framework.
- Enhance continuity of care across the continuum of health, from wellness and prevention through acute illness to recovery or rehabilitation.
- Improve patient and family satisfaction with care.
- Provide high-quality, cost-effective, evidence-based care that improves patient outcomes.
- Promote mutual respect, communication, and understanding between the patient and members of the healthcare team.
- Provide opportunities to address and resolve system-related issues and problems.
- Develop interdependent relationships and understanding among providers and patients.

Benefits of Interprofessional Collaboration

According to the World Health Organization (WHO), collaborative practice involves healthcare providers from a variety

of disciplines working in tandem with patients, families, caregivers, and communities to provide the best possible quality of care. Collaboration has system-wide effects. WHO has linked interprofessional collaboration with a number of improved patient outcomes ranging from infectious disease to chronic disease as well as patient safety indicators such as complications, error rates, patient length of stay, and mortality (WHO, 2010).

A collaborative approach to healthcare ideally benefits patients, professionals, and the healthcare delivery system. Because care becomes patient centered and, most important, patient directed, patients are empowered as informed consumers and actively collaborate with the healthcare team in the decision-making process. When patients are empowered to participate actively and professionals share mutually set goals with patients, quality of care improves and everyone—including the organization and healthcare system—ultimately benefits. When quality improves, adherence to therapeutic regimens increases, lengths of stay decrease, and overall costs to the system decline. Sound application of collaborative strategies leads to decreased patient morbidity and mortality rates (Schneider, 2012). When professional interdependence develops among healthcare providers, collegial relationships emerge and overall job satisfaction increases.

The Process of Interprofessional Collaboration

A continuum of collaboration, as illustrated in **Figure 37-2** », reflects the following levels of communication and action, beginning with parallel communication and progressing toward co-management and referral:

- **Parallel communication** occurs when each professional communicates with the patient independently and asks the same or similar questions.
- **Parallel functioning** occurs when communication may be more coordinated, but each professional has separate interventions and a separate plan of care.
- **Information exchange** involves planned communication, but decision making is unilateral, involving little, if any, collegiality.
- **Coordination and consultation** represent midrange levels of collaboration seeking to maximize the efficiency of resources.
- **Co-management and referral** represent the upper levels of collaboration, where providers retain responsibility and accountability for their own aspects of care and patients are directed to other providers when the problem is beyond the initial provider's expertise.

Characteristics of effective interprofessional collaboration include the following:

1. Common purpose and goals identified at the outset
2. Clinical competence of each provider
3. Interpersonal competence
4. Humor
5. Trust
6. Valuing and respecting diverse, complementary knowledge.

Processes associated with these characteristics include recurring interactions that develop connections and, therefore, mutual respect and trust among the healthcare professionals. Interpersonal skills and respect for the competence of all collaborators are essential to achieving greater health outcomes for patients.

Interprofessional collaboration has positive psychosocial and professional effects as well. Both patients and nurses perceive a greater sense of autonomy when collaborative strategies are applied (Schneider, 2012). Within the context of workplace roles, autonomy refers to the ability of a professional to employ appropriate interventions as they relate to the quality and safety of patient care (Bularzik et al., 2013). For nurses, practicing autonomously means being authorized to provide nursing care that falls within the professional scope of practice as defined by existing regulatory boards, professional organizations, and institutional rules (Weston, 2008, 2010) while grounded in informedness, voluntariness, consent, and rationality (ANA, 2015). The ability to fully enact one's professional role contributes to career satisfaction, career retention, decreased absenteeism, and decreased turnover (Bularzik et al., 2013).

Interprofessional Settings

Interprofessional teams and collaborations can occur in any setting in which healthcare is provided, not just within a hospital. Examples of interprofessional settings outside the hospital environment include:

- **Skilled nursing, rehabilitation, and long-term care facilities:** Patients admitted to these facilities often require care from multiple disciplines, including nursing; medical (physician, nurse practitioner, specialist); physical, occupational, speech/language, or respiratory therapy; social services; and mental health or psychiatric services.
- **Schools and educational settings:** Children with special needs, children who are medically fragile, and children with acute or chronic conditions may require long- or short-term interprofessional care from nurses, teachers, school administrators or counselors, mental health specialists,

Highest level				Lowest level		
Referral	Co-management	Consultation	Coordination	Information exchange	Parallel functioning	Parallel communication

Figure 37-2 » Continuum of collaboration.

physical therapists, occupational therapists, speech/language therapists, physicians, and others.

- **Assertive community treatment (ACT):** ACT provides mental health and support services in the community for individuals with serious mental illness, such as schizophrenia or bipolar disorder, to promote optimal functioning at home and within the community. Professionals participating in an individual patient's care team may include psychiatrists, psychologists, social workers, pharmacists, advanced practice nurses, employment counselors, and peer support specialists.
- **Elder care centers and services:** Programs such as Programs of All-Inclusive Care for the Elderly (PACE) offers services for older adults on an inpatient or outpatient basis as appropriate. Services may include medically necessary services, respite care for caregivers, transportation to medical and social services appointment, and mental healthcare. Collaborative team members may include physicians, nurses, nutritionists, therapists, social workers, and mental health professionals, among others.

Conflict Prevention and Management

Conflict occurs when diverse interests about significant issues or concerns among individuals, groups, or organizations prevents progressive problem solving or when emotional opposition creates discord and stifles effective communication (Schermerhorn et al., 2012; Waite & McKinney, 2014). Conflict is a normal part of the work environment. Worldwide, nurses compose up to 80% of the healthcare workforce and deliver 90% of all healthcare services (International Council of Nurses, 2012). Considering the number of individuals with whom they must collaborate to provide care, conflict should be anticipated (Waite & McKinney, 2014). Responses to conflict depend on the nurse's leadership skills for effecting positive outcomes within the work environment. Conflict (both between individuals and within an organization) can never be eliminated; however, it can be managed, and it takes both skill and competence in order to be successful.

Types of Conflict

Conflicts can take place between individual nurses, between nurses and patients or family members, between nurses and other members of the healthcare team, within a unit, or within a department. Conflicts can be interunit and interdepartmental, can affect the entire organization, or can even occur between multiple organizations, between or within teams or units, or between an organization and the community.

Levels of Conflict

Types and levels of conflict may be categorized in a variety of ways. This section approaches conflict as existing on four levels (Schermerhorn et al., 2012):

- **Intrapersonal conflict**, which occurs within an individual, is stress or tension that results from real or perceived pressure generated by incompatible expectations or

goals. This may occur when an individual is expected to do something that produces both desirable and undesirable consequences. For example, intrapersonal conflict may occur when a nurse must choose either to accept an employment position that interferes with fulfilling family-related responsibilities or to prioritize family responsibilities while remaining unemployed and without an income (Schermerhorn et al., 2012).

- **Interpersonal conflict** occurs between two or more individuals. It can arise from differences in goals or personalities, competition, or concern about territory, control, or loss. Interpersonal conflict may occur in the workplace when one staff member misunderstands the roles or responsibility of another. For example, a nurse may believe that someone from another discipline is not doing his or her job because the individual is neglecting to perform an activity that is really the responsibility of the nurse. Other interpersonal conflicts can arise as the result of bullying, when a member of the team belittles another or attempts to coerce others into behaving in ways that cause frustration, guilt, or other types of conflict.
- **Intergroup conflict** occurs between teams that are in competition or opposition to one another. In some cases, the groups are competing for rewards or scarce resources. The groups may also be emotionally opposed to each other (Schermerhorn et al., 2012). One example of this level of conflict is the debate that is occurring between physician groups who want to bring nurse practitioners under the control of the medical board, whereas nurses feel strongly that nurse practitioners should remain under the control of the board of nursing.
- **Interorganizational conflict** is most commonly considered to involve competition between two organizations that exist within one market (Schermerhorn et al., 2012). For example, hospitals within the same community may demonstrate interorganizational conflict, with different institutions advertising superior care for a subset of patients; or, colleges of nursing may compete for qualified applicants for program admission.

Covert and Overt Conflict

At any level, conflict may be overt or covert. Both approaches may be associated with benefits, as well as with negative consequences. In **overt conflict**, the individuals or group members who are in conflict address the conflict openly. Overt conflict is obvious, at least to most individuals, and thus coping with it is usually easier. Generally speaking, it is easier to arrive at an agreement that conflict is present and easier to arrive at a description of the conflict.

In **covert conflict**, the conflict is not discussed openly. It may be avoided or ignored. Covert conflict may be exhibited in reactive, repressive, and avoidant behaviors. Reactive behaviors include whining, complaining, agreeing with others without really listening to them, and passive-aggressive behavior. Gossip is another form of reactive behavior, and rumor mills are common in workplaces in which covert conflict thrives. Repressive behaviors include absenteeism and tardiness. Although sustained avoidance usually is associated with negative outcomes, it is worth noting that avoidance may be an effective method of temporarily managing

conflict. Avoidance may be appropriate when emotions are flaring and the individual or individuals involved would benefit from taking time to regain composure before discussing the issues at the foundation of the conflict (Schermerhorn et al., 2012). However, sustained tactics of covert conflict result in increased stress, distress, and confusion about how to address the conflict. Acknowledging covert conflict is not easy, and everyone involved will have different perceptions of the conflict because it operates below the surface.

Causes of Conflict

To resolve conflict effectively, nurses must understand its cause. Some conflicts have more than one cause. Typical causes of conflict among individuals and among groups include the following: miscommunication, inaccurate information, mistrust, ambiguous role expectations, ineffective leadership, and resistance to change.

Within the healthcare setting, researchers have identified role boundary issues and accountability as two primary sources of conflict (Brown et al., 2011). Conflicts arising from role boundary issues include a lack of understanding of the value of all team members, including those outside the disciplines of nursing and medicine, relative to the care of the patient. Role boundaries also create conflicts with regard to awareness of which tasks each team member was authorized to perform. In the realm of accountability, conflict arises particularly when healthcare team members did not hold themselves accountable for their actions (Brown et al., 2011).

The Nurse–Physician Relationship

The nurse–physician relationship should be the strongest collaboration that nurses have in order to meet the needs of their patients. Unfortunately, it sometimes is not. This may be due to a lack of confidence on the part of the nurse, an attempt to save face, fear of repercussion, deference to the physician, or an attempt to preserve a patriarchal nurse–physician relationship (Matzke et al., 2014). Both nurses and physicians can contribute to inadequacies in this relationship. When conflict does occur, it often becomes a barrier to effective patient care. Cooperation and collaboration are also integral to the success of this relationship.

The Nurse–Patient Relationship

The close nature of the nurse–patient relationship allows little room for conflict between patient and nurse. Despite this, conflicts with patients or with family members or caregivers can arise. Causes of conflict in this relationship can include lack of knowledge on the part of the patient or family member; poor coping skills on the part of the patient or family member; fear or anxiety resulting in the patient or family member expressing frustration; and failure of the nurse to assess or meet patient needs or promote the therapeutic relationship. Whatever the cause, any conflict between the nurse and patient or family member can become a barrier to effective care.

Nurse–nurse and nurse–coworker conflicts also occur. When not managed properly, these may rise to the level of workplace bullying or incivility. Strategies for preventing

and managing conflict (including workplace bullying and incivility) are outlined in the sections that follow.

Clinical Example B

Josiah Elliot, 72 years old, is admitted to the hospital with medical diagnoses of congestive heart failure, chronic renal failure, hypertension, and benign prostatic hypertrophy. The nurse admits him and develops his plan of nursing care, including the nursing diagnoses of *Excess Fluid Volume*, *Urinary Retention*, *Impaired Gas Exchange*, and *Anxiety* related to hypoxia. Three days later Mr. Elliot has lost 18 pounds and is breathing more easily. He also denies feeling anxious and reports, “I’m relaxed now that I can breathe!” The nursing diagnoses of *Excess Fluid Volume*, *Impaired Gas Exchange*, and *Anxiety* are all marked as resolved. During morning rounds, the nurse provides the physician with an update on the patient’s condition and questions the need to continue administering the large doses of diuretics that were ordered when the patient was admitted. The physician agrees and reduces the dosage of the medications. The physician raises concerns about the patient’s nutritional status and suitability for discharge to home. After some discussion, the physician and nurse agree to consult with a dietitian and a social worker for further evaluation of the patient’s care.

Critical Thinking Questions

1. Describe the impact of the team’s collaborative approach on Mr. Elliot’s outcomes.
2. How might Mr. Elliot’s care have differed if the team had not collaborated?
3. What further collaboration is indicated in providing care for Mr. Elliot?

Developing Conflict Competence

Caring for individuals requires groups of professionals working together in interprofessional settings. Resolving conflict requires increased cognitive, emotional, and behavioral skills, confidence, and competence. Purposeful development of these skills is also known as **conflict competence** (Waite & McKinney, 2014). Communication is key for both preventing and resolving conflict. Five different communication styles have been identified in the literature and have been repeatedly tested using the Thomas-Kilmann Conflict Mode Instrument (TKI). Those styles include:

1. **Competing:** An assertive, power-oriented approach; competing can be seen as self-centered or as defending one’s position on behalf of the patient.
2. **Collaborating:** A cooperative approach; gaining insight to the perspectives of others can lead to creative problem-solving.
3. **Compromising:** An approach in which both parties are partially satisfied; compromising, at the very least, addresses rather than avoids the issue.
4. **Avoiding:** Seen as uncooperative or a preference to avoid addressing the conflict; however, avoidance can be a helpful approach when more information is needed or when the issue just is not worth risking further conflict or a loss of opportunity or consideration.
5. **Accommodating:** An attempt to satisfy the concerns of others while neglecting the self; accommodation works best when one individual or group is less interested in the issue than the other.

The ability to move among styles, depending on the situation at hand, is a skill that takes practice and awareness of

self in order to develop one's conflict competence (Thomas & Kilmann, 1974).

Interprofessional communication has been identified by The Interprofessional Education Collaborative (IPEC) as one of its four core competencies as a framework for collaboration and practice (along with values & ethics, roles & responsibilities, and teams & teamwork) (NLN, 2015).

Communication can be status-based or team-centered. Status-based communication is, as the term implies, based on a hierarchy, typically the physician "giving orders" as the team captain. This type of communication focuses on the needs/desires of one individual (the physician) and/or the more powerful team member using forceful language to convey or reaffirm status. This approach does not lend itself to dialogue. Team-centered communication emphasizes shared problem-solving. Rather than the "I want" or "You need to do x" with the status-based approach, the team-centered approach invokes "How can we solve x" as a common strategy. Practice using "we" statements such as "Mr. X is concerned about. . . . What are your thoughts on this?" or "How can we work together to help him?" Statements such as these reflect shared responsibility and encourage open discussions (Matzke et al., 2014).

Using a relational approach helps individuals understand their own responses to conflict. The fundamental components of a therapeutic relationship—demonstrating respect, being self-aware, maintaining boundaries within the professional team, being empathetic, accepting individuality, and promoting equality among team members—are vital in communication. These qualities lay the groundwork for approaching communication about patient problems as one would in a relationship, moving from individual or "I" statements to "how best can we" type conversations that invite openness in dialogue. Using a relational approach can improve care coordination, which can, in turn, lead to better clinical outcomes (Gerardi, 2015a).

Preventing Conflict

Clear communication is essential to prevent misunderstandings that can lead to conflicts. Understanding and recognizing causes of conflict can assist individuals and organizations to develop strategies to prevent conflict. Nurses must be able to identify potential issues that can act as barriers to conflict resolution or increase the likelihood that a situation will turn into a conflict. First and foremost, nurses need to recognize their own tension or stress level in the workplace.

Mindsight is a term that describes being self-aware of one's triggers to stress that can result in conflict, and purposefully "retraining" the brain to respond differently. Improving one's self-awareness is salient to growing as a leader and being able to redirect the typical response and course of action in a given situation. Taking steps to decrease or manage stress levels helps to reduce the likelihood of initiating conflict (see Focus on Integrative Health: Stress Reduction). Other strategies that help prevent conflict include the following (Greenberg, 2011; Porter-O'Grady & Malloch, 2013):

- Address issues as they arise.
- Avoid destructive criticism, including harsh words, threats, and generalized condemnation of behaviors or performance.

- Treat others with respect, which will decrease defensiveness.
- Avoid arguments. Sometimes people do need to vent, and as long as it is done appropriately and in a private place, it may be helpful in decreasing tension.
- Actively listen to each other.
- Consider the other individual's point of view, including cultural beliefs and values.

For individuals who are in leadership roles, strategies to promote conflict prevention include the following (Greenberg, 2011; Porter-O'Grady & Malloch, 2013):

- Allocate resources fairly, including fair distribution of workload balance and intensity when assigning patient care.
- Clearly define role expectations for all team members.
- Encourage staff to provide feedback and identify potential concerns without the threat of punitive action.
- Acknowledge team members' accomplishments and achievements, as well as significant life events.

Responding to Conflict

Not everyone responds to conflict in the same way, and individuals vary in how they respond to it in different circumstances. Often, interactions may be unpredictable and the accompanying behaviors unpredictable. In turn, one's response to such behaviors can trigger an unreasonable or inappropriate retort. Typical responses might be avoidance, minimizing, or prematurely "fixing" the problem but not the root cause. Such responses can set up barriers and prevent successful engagement and problem solving (Gerardi, 2015b).

When conflict occurs, each individual involved has a personal perspective of the issue and conflict. The nurse who can recognize the types of responses to conflict will be better equipped to predict and manage it. To respond effectively to conflict, the nurse should apply the following guidelines:

- Demonstrate honesty, trustworthiness, and respect.
- State the issue objectively and provide a factual basis for the concern.
- Avoid emotion-based discussions.
- Be open to hearing all individuals' viewpoints and avoid passing judgment.

Focus on Integrative Health Stress Reduction

Integrative health approaches can have a positive impact for stress reduction. Knowing oneself and what is likely to trigger a reaction or a response to stress can be tempered by using integrative approaches, such as progressive relaxation, meditation, guided imagery, breathing exercises, aerobic exercise, and meditative movement therapies, including yoga and t'ai chi. Any method selected requires practice to improve adherence to health-promoting behaviors and lifestyle modifications. In the stressful world of nursing, early adoption of one or more of these approaches is encouraged in order to successfully deal with day-to-day events (Cramer et al., 2014).

- Allow all individuals involved to express their concerns without interruption.
- Apply active listening techniques.
- Focus on identifying solutions as opposed to exacerbating the problem.
- Throughout the process of conflict resolution, recognize that the delivery of safe, effective patient care is the central concern.

Managing Conflict Within the Healthcare Team

The common assumption about conflict is that it is destructive, and it certainly can be. However, when effectively managed, conflict can bring to light issues that need to be addressed and result in beneficial outcomes for individuals, groups, and organizations (Schermerhorn et al., 2012).

Nurses tend to resort to positions of avoidance, compromise, or accommodation rather than address an issue or deal with conflict. Such approaches, over time, can lead to resentment, which can further lead to ambivalence about one's job. Anticipating that conflict will occur and being prepared to deal with and manage conflict constructively is a leadership skill. Learning to manage and/or resolve conflict successfully is essential for professional growth. Although often viewed as being negative, conflict can actually be an impetus for better communication, stronger team relationships, and healthy changes. Nurses need to be able to competently and confidently address difficult situations in a constructive manner and in a safe space where all parties feel that they can have conversations about perceptions or misperceptions without fear of retribution. Successfully addressing conflict requires self-awareness for knowing how one responds in stressful situations. Self-inventory tools help to provide understanding of how one reacts to situations that trigger conflict. Self-awareness is key to therapeutic and respectful relationships. Personal inventories such as the Thomas-Kilmann Conflict Mode Instrument (Thomas & Kilmann, 1974), StrengthsFinder (Rath, 2007), and Emotional Intelligence Inventory (Stein & Book, 2000), to name but a few, help to increase personal awareness about personal reflexive responses that might hamper rather than help in stressful situations. Understanding one's own responses is important to reflect and learn how to change one's behavior from a reactionary stance to a relatable and intentional approach (Gerardi, 2015a; Waite & McKinney, 2014). At an organizational level, agency administrations need to promote programs that go beyond assertiveness training, conflict management, and collaborative processes. Agencies must engage employees in institution-wide programs that emphasize respect, acknowledge communication for the sake of patient safety, use nondisciplinary approaches to resolve issues, and model language and tactics that reduce tension and remove the barriers that impede resolution. Examples of these types of programs include Crucial Conversations, Crew Resource Management, TeamSTEPPS, and The Exchange (Rosenstein, Dinklin, & Munro, 2014).

Managing Conflict with Patients and Families

When conflict occurs with patients or their families, in addition to the strategies already presented, setting limits can be an effective way to manage expressions of negative behaviors.

For example, nurses set limits when a patient becomes loud or profane by providing instructions such as "I can see you are upset and I want to help you, but I will not tolerate abusive language." Setting limits can help anxious patients monitor their own behaviors and keep the nurse from being interrupted too frequently.

Patients or families should never be allowed to demonstrate anger inappropriately. When this occurs, the nurse needs to set reasonable limits that are based on an assessment of the situation. Anger and inappropriate behavior may stem from a number of causes, such as pain, medications, fear and anxiety, psychosis, and dysfunctional communication. Cultural differences must also be considered. Language barriers may result in misunderstandings, frustrations, and unmet needs, and some patients may display anger as a result. Further, some cultures consider it appropriate to be very emotional while others do not. In the long term, active listening and clear communication are critical to prevent and manage conflict. Although empathy and consideration are key components of the nurse's role, abusive behavior is never acceptable. Tolerance of verbal or physical acts of aggression may lead to escalation of these behaviors. To promote safety for both the healthcare provider and the patient, inappropriate demonstrations of anger, including hostile verbal or physical behaviors, should be reported immediately to the team leader or charge nurse.

Incivility in the Workplace

Incivility or disruptive behavior in the workplace can play out in many forms, including aggression, bullying, and violence. Studies on incivility indicate that such negativity can lead to adverse organizational outcomes, including decreased job satisfaction leading to absenteeism; loss of productivity; staff turnover; patient errors with the potential for adverse outcomes; and the associated costs of turnover or legal fees to resolve staff or patient issues. Although numbers vary, the financial burden is estimated to be more than \$23 billion to cover the costs of uncivil workplace behaviors and associated outcomes (Lachman, 2015; Laschinger et al., 2014). The problem is more widespread than reports indicate, partly because individuals may not report out of fear of retribution, lack of knowledge of the reporting process, or an assumption that the behavior is acceptable. Other factors that discourage reporting of incivility in the workplace include the failure of administration to support or respond to previous reports and the overall lack of awareness on the part of the individual or the staff as a result of the normalization of the activity.

Aggressive or hostile behavior can lead to conflict. Aggressive behavior by even a single individual in the workplace can increase the anxiety of many others. The first response toward a hostile staff member should be to communicate control to that staff member and to insert calm into the situation. When the nurse manager or team leader is the one who is hostile, the situation carries greater complexity and requires assistance from higher level management. Regardless of who is exhibiting aggression or hostility, someone should gain control and try to move the aggressor to a private place. Demonstrations of open conflict with hostility should not take place in patient or public areas. If the

suggestion to move to a private area does not work and the situation continues to escalate, simply walking away may help set some boundaries. This allows time for all parties to take a breath, calm down, and revisit the situation at a more appropriate time.

Workplace Bullying

Workplace bullying is a long-term behavior lasting a minimum of 6 months and plays out in the form of verbal attacks, refusal to help or assist others, speaking negatively or taunting. When not effectively managed or controlled, workplace bullying can escalate to physical threats (Lachman, 2015).

Verbal abuse in professional settings is defined as malicious, repeated, harmful mistreatment of an individual with whom one works, regardless of whether that individual is an equal, a superior, or a subordinate. Verbal abuse occurs in healthcare settings between patients and staff, nurses and other nurses, physicians and nurses, and all other staff relationships.

Horizontal violence (HV) is a term used to describe aggressive acts committed against a nurse by one or more nursing colleagues (Longo & Sherman, 2007; Purpora & Blegen, 2012). Behaviors that reflect HV may include verbal acts, such as gossiping about and speaking sarcastically to the nurse who is the target, unkind or even antagonistic interactions, divisive behavior, sarcasm, and condescending or patronizing behavior (Lachman, 2015).

In any form, workplace bullying yields serious negative consequences. Victims of bullying experience adverse emotional effects, including depression, anxiety, and a sense of isolation (Murray, 2008, 2009). In healthcare organizations, research suggests that bullying is linked to increased rates of employee absenteeism and work-related injuries as well as decreased productivity (Felblinger, 2008; Longo & Sherman, 2007; Murray, 2008). It can impact patient safety and quality of care.

Incivility and disruptive behaviors violate the ANA *Code of Ethics for Nurses* (2015). Provision 1.5 of the code speaks to collegial relationships with others and the nurse's obligation to create a culture of civility and kindness. Provision 6 addresses the nurse's responsibility for creating a culture of excellence (ANA, 2015; Lachman, O'Connor Swanson, & Winland-Brown, 2015). In addition, within the Core Competencies for Interprofessional Collaborative Practice is the values/ethics competency stipulating that healthcare team members must place the interests of patients and populations at the center of care (Interprofessional Education Collaborative Expert Panel, 2011).

Maintaining a Culture of Excellence

Nurses have an obligation to create and maintain a culture of excellence, and within that is the obligation to report bullying. Nurses should recognize workplace bullying, be aware of its effects, and follow organizational policies and procedures with regard to reporting the behavior. Reports of bullying should include details such as the date, time, and description of events, as well as identification of any witnesses. Ideally, individuals in leadership positions within the organization will address the issue in such a manner that the bullying stops. The nurse should be aware of organizations that may be available to provide assistance

Box 37-3

Prevention of Workplace Bullying Among Nurses

- Educate team members about bullying behaviors and their adverse effects.
- Develop codes of conduct that clearly outline unacceptable behaviors.
- Promote a "zero-tolerance" attitude toward bullying.
- Encourage nurses to report bullying without fear of punishment or negative consequences.
- Offer the option of reporting bullying behaviors or recommendations for improvement of anti-bullying policies through use of comment or suggestion boxes.
- Assure nurses that reports of bullying will be taken seriously and thoroughly addressed, including through mandatory investigations of all allegations of bullying.
- Train leadership and management personnel to work collaboratively to prevent, identify, and address bullying behaviors.
- Create an environment in which courtesy and respect are valued.

Bullying in a caring profession: Reasons, results, and recommendations. *Journal of Psychosocial Nursing and Mental Health Services*, 49, 30–35; Cleary, M., Hunt, G. E., Walter, G., & Robertson, M. (2009). Dealing with bullying in the workplace: Toward zero tolerance. *Journal of Psychosocial Nursing and Mental Health Services*, 47, 34–41; and Mackintosh, J., Wuest, J., Gray, M. M., & Cronkhite, M. (2010). Workplace bullying in health care affects the meaning of work. *Qualitative Health Research*, 20, 1128–1141.

in case of bullying, including the appropriate state nursing association, the American Nurses Association, and the Department of Justice (Murray, 2009). Empowered nurses have access to information, support, and resources and work in environments whose leaders are committed to providing opportunities to learn and grow, all in an effort to minimize or greatly reduce workplace incivility (Laschinger et al., 2014). See **Box 37-3** » for an overview of guidelines for prevention of bullying among nurses in the workplace. **Box 37-4** » outlines the standards set by the American Association of Critical Care Nurses for establishing a healthy workplace. By following these standards, nurses and healthcare agencies can work to establish a culture of excellence.

Clinical Example C

Dee Johnston has worked in pediatric intensive care for the past year. She decides to leave her current position because she feels that her coworkers don't value the knowledge and skill that she has gained over time. Coworkers still make off-the-cuff remarks such as "She's just the newbie on the block" or "Wait until she has a really sick baby to deal with." Dee begins to feel nervous at the thought of just going to work and is afraid she is going to make a mistake. She decides to leave and accept a position as a staff nurse in the pediatric ICU at another facility. Within 3 weeks of orientation, her preceptor quickly recognizes her expertise and feels that additional orientation is unnecessary. She begins to gain more self-confidence and enjoys going to her job once again.

Critical Thinking Questions

1. How is Dee interpreting her coworkers' behavior?
2. Why might they be making such comments about Dee?
3. Do you think that leaving was the right thing for Dee to do? Why or why not?

Box 37–4

AACN Standards for Healthy Work Environments

The American Association of Critical Care Nurses (AACN, 2016) has worked diligently to promote healthcare environments that focus on meeting the needs of patients, families, nurses, and other healthcare professionals. As part of this work, the AACN has identified six essential standards based on evidence-based principles of professional performance. The six standards with sample critical elements include:

1. **Skilled communication**, with the expectation that individuals advance collaborative relationships, improve communication styles, establish zero-tolerance policies to protect against disrespectful behavior in the workplace, maintain accountability for words and actions, and encourage a focus on finding solutions and achievable outcomes.
2. **True collaboration**, wherein team members have access to interprofessional education opportunities, have high levels of integrity, and demonstrate competence in their roles.

3. **Effective decision making**, which ensures that nurses participate in all levels of decision making, that team members share fact-based information, and that effective processes are in place to objectively evaluate the results of decisions.
4. **Appropriate staffing** based on the professional obligation for nurses to provide high-level quality care and that organizations adopt technologies that increase the effectiveness of care.
5. **Meaningful recognition**, which acknowledges that team members should be recognized for the value they bring to the organization.
6. **Authentic leadership**, whereby leaders fully embrace and sustain a healthy work environment that promotes professional advancement.

REVIEW The Concept of Collaboration

RELATE Link the Concepts

Linking the concept of collaboration with the concept of communication:

1. How does the nurse's communication skills affect his or her ability to collaborate?
2. How does communication style affect the process of collaboration? Give some examples.

Linking the concept of collaboration with the concept of oxygenation:

3. How would the care of a patient with chronic obstructive pulmonary disease (COPD) benefit from a nurse who collaborates well with other members of the healthcare team?
4. In caring for the patient with COPD, what aspects of care would require collaboration?

Linking the concept of collaboration with the concept of stress and coping:

5. How do different levels of stress affect both the occurrence of conflict and the management of conflict that arises?
6. How can an understanding of different individuals' coping mechanisms improve the ability to manage conflict?

REFLECT Apply Your Knowledge

Abigail Lessarian, a 32-year-old patient, delivered her first baby prematurely at 32 weeks' gestation. Her infant son, Garrett, was apneic at birth and required a brief period of tracheal intubation and mechanical ventilation. Immediately after his delivery, Garrett was admitted to the neonatal intensive care unit (NICU) for treatment of neonatal respiratory distress syndrome (RDS). By day 3, Garrett had made excellent progress; he was extubated and oxygen administration was implemented via nasal cannula with continuous positive

airway pressure (CPAP). By day 14 in the NICU, Garrett was breathing effectively enough to maintain his oxygen saturation at >98% on room air with CPAP via nasal cannula; however, he experienced intermittent apneic spells with bradycardia until day 22. Garrett also was diagnosed with an atrial septal defect (ASD), which his surgeon recommended monitoring in hopes that the ASD would resolve without requiring surgical treatment. He received gavage feedings via a nasogastric tube.

By day 30 in the NICU, Garrett had experienced no apneic spells for 7 days. On day 32, Garrett's gavage tube was removed, and he successfully transitioned to bottle feeding over a period of several days. On day 43, Garrett began transitioning to breastfeeding; despite having difficulty with sucking, his progress was slow but steady. By day 46, Garrett's neonatologist (pediatrician specializing in neonatal care) cleared him for discharge to home.

Prior to Garrett's discharge, his mother and father are scheduled to complete an infant CPR course. They also will receive teaching about the use of a home apnea monitor. During discussion of the numerous topics about which Garrett's parents will receive instruction, Garrett's mother states, "I don't know if I can handle much more. I feel so overwhelmed." When she becomes tearful, her husband puts his arm around her and says, "We'll do whatever it takes to help him get healthy. I can't believe I was concerned about whether or not he'd like playing baseball or football. Now, that seems so silly. I just want him to survive."

1. Identify three nursing diagnoses that are appropriate for inclusion in Garrett's nursing plan of care.
2. Identify three nursing diagnoses that are appropriate for inclusion in the nursing plan of care for Garrett's parents.
3. During preliminary discharge planning, Garrett's interprofessional team's recommendations include home visits by a nurse, occupational therapist, and social worker. What roles might each of these professionals serve in the care of Garrett and his family?
4. What other professionals might be beneficial to the care of Garrett and his parents in the home setting?

Module 38

Communication

Module Outline and Learning Outcomes

The Concept of Communication

The Communication Process

38.1 Analyze the process of communication.

Modes of Communication

38.2 Differentiate the various forms of communication.

Concepts Related to Communication

38.3 Outline the relationship between communication and other concepts.

Factors Influencing the Communication Process

38.4 Analyze the factors that influence the communication process.

Barriers to Communication

38.5 Analyze barriers to effective communication.

Types of Communicators

38.6 Analyze the various types of communicators.

Assertive Communication

38.7 Summarize the attributes of a nurse who uses assertive communication.

Lifespan Considerations

38.8 Differentiate considerations related to communication throughout the lifespan.

Nursing Practice

38.9 Analyze the nursing process as it relates to a patient with impaired verbal communication.

Communication Exemplars

Exemplar 38.A Groups and Group Communication

38.A Analyze groups and group communication.

Exemplar 38.B Therapeutic Communication

38.B Analyze the interactive process of therapeutic communication.

Exemplar 38.C Documentation

38.C Analyze documentation as it relates to communication.

Exemplar 38.D Reporting

38.D Analyze reporting as it relates to communication.

Nursing involves interactions between nurses and patients, nurses and other health professionals, and nurses and the community. The process of human interaction occurs through communication: verbal and nonverbal, written and unwritten, planned and unplanned. Communication between individuals conveys thoughts, ideas, feelings, and information. To be effective in their interactions, nurses must be proficient in their verbal and written communication

skills. They must be aware of what their words and body language say to others. Nurses also must demonstrate competency in computer and electronic communication skills.

The term *communication* has various meanings, depending on the context in which it is used. For example, communication can be the interchange of information, thoughts, or ideas between two or more individuals. This kind of communication uses methods such as talking and listening or

writing and reading. However, thoughts and ideas can be conveyed to others not only through spoken or written words but also through gestures or body actions.

In healthcare professions, sometimes a nurse or physician is said to be lacking in “bedside manner.” A failure on the part of a healthcare professional to communicate successfully with a patient or other healthcare professional can result in poor health outcomes for the patient. This section on the concept of Communication provides nurses with essential information they need in order to communicate successfully with patients, peers, and other healthcare professionals. For the purposes of this text, **communication** is any means of exchanging information or feelings between two or more individuals. Communication is a basic component of human relationships, including nursing.

The *intent* of any communication is to elicit a response. Thus, communication is a process that has two main purposes: to influence others to respond and to obtain information. Communication can be described as helpful or unhelpful. Positive or effective communication encourages a sharing of information, thoughts, or feelings between two or more individuals. Negative or ineffective communication hinders or blocks the transfer of information and feelings. In nursing, any form or failure of communication that prevents the sharing of information and feelings can have negative consequences for the patient.

Therapeutic as opposed to social communication is essential for the establishment of a healthy nurse–patient relationship. Nurses who communicate therapeutically are better able to collect assessment data, develop care plans in collaboration with patients, initiate interventions, evaluate outcomes of interventions, initiate changes that promote health, and prevent legal problems associated with nursing practice. This communication process depends on nurses having established trusting relationships with patients and caregivers.

The Communication Process

Face-to-face communication involves a sender, a message, a receiver, and a response, or feedback (Figure 38-1 »). In its simplest form, communication is a two-party process involving the sending and the receiving of a message. Because the intent of communication is to elicit a response, the process is ongoing: The receiver of the message then becomes the sender of a response, and the original sender in turn becomes the receiver.

During any communication interaction, communication is also occurring on an intrapersonal level—that is, an

Figure 38-1 » The communication process. The dashed arrows indicate intrapersonal communication (self-talk). The solid lines indicate interpersonal communication.

individual’s thoughts are a form of communication. Intrapersonal communication, also called *self-talk*, describes the thoughts or communication individuals keep to themselves. Each individual will be thinking his or her own thoughts before, during, and after sending a message and while receiving a message from the other party. This intrapersonal communication occurs constantly and can interfere with an individual’s ability to hear a message as the sender intended (Figure 38-2 »).

Sender

The **sender**, an individual or group who wishes to convey a message to another, can be considered the *source-encoder*. This term suggests that the person or group sending the message must have an idea or reason for communicating (source) and must put that idea or reason into a form that can be transmitted. **Encoding** involves the

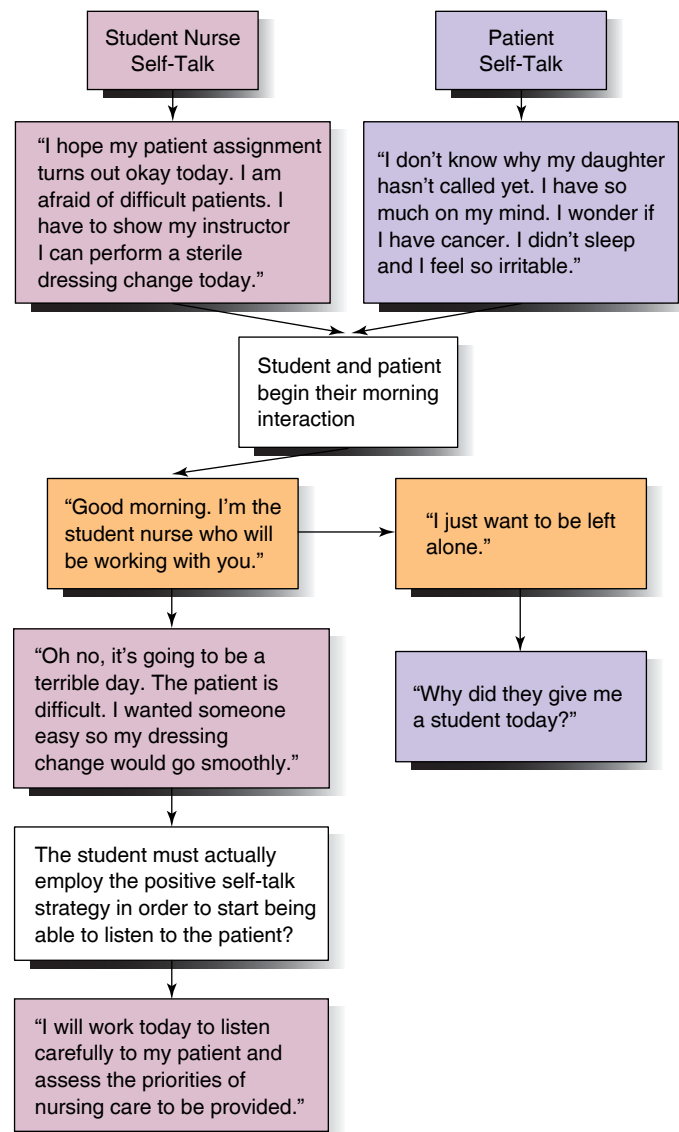

Figure 38-2 » Improving student nurse self-talk. The nurse’s self-talk is shown in pink. The patient’s self-talk is shown in purple. The verbal communication is shown in orange. Commentary is shown in white.

selection of specific signs or symbols (codes) to transmit the message, such as which language and words to use, how to arrange the words, and what medium to use, which may involve tone of voice and gestures in oral communication. For example, if the receiver speaks English, the sender usually selects English words. If the message is “Mr. Johnson, you have to wait another hour for your pain medication,” the tone of voice selected and a shake of the head can reinforce the message. Nurses must not only deal with dialects and foreign languages, but they must also cope with two language levels: the patient’s and their own.

Message

The next component of the communication process is the **message** itself—the words actually spoken or written, the body language that accompanies the words, and how the words are transmitted. The medium used to convey the message is the **channel**, and it can target any of the receiver’s senses. The channel must be appropriate for the message, and it should help make the intent of the message clearer. In some instances, for example, talking face to face with an individual may be more effective than telephoning or writing a message. Using recorded messages or communicating by radio or television may be more appropriate for large audiences. Written communication is often appropriate for long explanations or for a communication that needs to be preserved. The nonverbal channel of touch is often highly effective in establishing a bond or connection with the receiver. Some of the most effective communications use more than one sensory channel—for example, the nurse may combine the use of therapeutic touch with her verbal message.

Receiver

The **receiver**, the third component of the communication process, is the listener, who must listen, observe, and attend. This person is the *decoder*, who must perceive what the sender intended (interpretation). Perception entails using all of the senses to receive verbal and nonverbal messages. To *decode* means to relate the message perceived to the receiver’s storehouse of knowledge and experience and to sort out the meaning of the message. Whether the receiver accurately decodes the message according to the sender’s intent depends largely on their similarities in knowledge, experiences, and sociocultural background. If the meaning of the decoded message matches the intent of the sender, then the communication has been effective.

Ineffective communication occurs when the sender’s message is misinterpreted by the receiver. For example, if a nurse preparing to feed a patient who requires assistance glances repeatedly at the clock, the patient may interpret this behavior as indicating that the nurse is in a hurry, which may make the patient feel rushed and like a burden. It is important for nurses to consider the unintended messages their behavior may be sending.

Response

The **response**, the fourth component of the communication process, is the message that the receiver returns to the sender. It is also called **feedback**. A response can be either verbal, nonverbal, or both. A nod of the head or a yawn is an

example of a nonverbal response. Either way, feedback allows the sender to validate that the intended message has been received and correctly understood and, if not, then it provides the sender an opportunity to correct or reword a message. In the case of Mr. Johnson, who was told that he would have to wait an hour for his pain medication, the receiver may appear irritated and say, “Well, the nurse on the other shift gives me my pain medication early if I need it.” The sender then knows the message was interpreted accurately. However, now the original sender becomes the receiver, who is required to decode and respond.

Modes of Communication

Communication is generally carried out in two different modes: verbal and nonverbal. **Verbal communication** uses the spoken or written word; **nonverbal communication** uses other forms, such as gestures, facial expressions, and touch. Although both kinds of communication occur concurrently, the majority of communication is nonverbal. Learning about nonverbal communication helps the nurse develop effective communication patterns and relationships with patients. A mode of communication that has evolved with technology is **electronic communication**. Email is perhaps the most common form of electronic communication, although social networking and text messaging are used frequently outside the workplace. It is important for the nurse to know when it is appropriate and not appropriate to use email and other forms of electronic communication to communicate with patients.

Verbal Communication

Because individuals choose the words they use, verbal communication is largely a conscious and purposeful activity. Words and phrasing used vary among individuals according to culture, socioeconomic background, age, and education. An abundance of words can be used to form messages. In addition, a wide variety of feelings can be conveyed when people talk. As a result, countless possibilities exist for the way ideas and information can be exchanged.

When choosing what words to say or write, the nurse needs to consider pace and intonation, simplicity, clarity and brevity, timing and relevance, adaptability, credibility, and humor.

Pace and Intonation

The manner of speech, as in the pace or rhythm and intonation, will affect the feeling and impact of the message. The intonation can express enthusiasm, joy, sadness, anger, or amusement. The pace of speech may indicate interest, anxiety, boredom, or fear. For example, speaking slowly and softly may help calm an excited patient.

Simplicity

Simplicity of speech refers to the use of commonly understood words, brevity, and completeness. Words such as *vasoconstriction* or *cholecystectomy* are meaningful to the nurse and may be easy for the nurse to use, but they are not meaningful to patients who have no background in health-care. Nurses need to learn to select understandable terms that are appropriate for the developmental stage, knowledge, culture, and education of the patient. For example,

instead of saying to a patient, “The nurses will be catheterizing you tomorrow for a urine analysis,” it may be better to say, “Tomorrow we need to get a sample of your urine, so we will collect it by putting a small tube into your bladder.” The latter statement is simpler and therefore easier to understand. It is more likely to convey to the patient why the procedure is needed and whether it will be uncomfortable.

Clarity and Brevity

The most effective type of message is one that is direct and simple. *Clarity* is saying precisely what is meant, and *brevity* is using the fewest words necessary. Using clarity and brevity results in a message that is simple and clear. An aspect of this is **congruent communication**, in which the nurse’s behavior or nonverbal communication is congruent (consistent) with the words spoken. When the nurse tells the patient, “I am interested in hearing what you have to say,” the nurse should use nonverbal behavior that includes facing the patient, making eye contact (if culturally appropriate), and leaning forward. The goal is to communicate clearly so that all aspects of a situation or circumstance are understood. To ensure clarity in communication, the nurse also needs to speak slowly and enunciate carefully. Note that careful enunciation does not require speaking loudly. Speaking loudly to a patient, even if the patient is hard of hearing, especially in a quiet setting, may be experienced by the patient as patronizing or aggressive. This can undermine the nurse–patient relationship.

Timing and Relevance

The nurse needs to be aware of both relevance and timing when communicating with patients. No matter how clearly or simply words are stated or written, the timing needs to be appropriate to ensure that the words are heard and understood. Moreover, the message needs to relate to the person who is the receiver or to the person’s interests. This requires the nurse to be sensitive to the patient’s needs and concerns. For example, a patient whose current focus is her fear of cancer may not hear the nurse’s explanations about the upcoming gallbladder surgery. In this situation, the nurse should first encourage the patient to express her concerns and then deal with those concerns. The necessary explanations can be provided after the patient’s primary fears have been addressed or at another time when the patient is able to listen.

Adaptability

Nurses must alter spoken messages in response to behavioral cues from the patient. This adjustment is referred to as *adaptability*. Nurses carefully consider and individualize what they say and how they say it. This requires both astute assessment and sensitivity. For example, suppose that a nurse who usually smiles, appears cheerful, and greets a patient with an enthusiastic “Hi, Mrs. Brown!” notices that the patient is not smiling and appears distressed. In this situation, the nurse should modify her tone of speech and express concern via her facial expressions while moving toward the patient.

Credibility

Credibility is the quality of being truthful, trustworthy, and reliable. Credibility is essential to effective communication. Nurses foster credibility by being consistent, dependable,

and honest. Nurses need to be knowledgeable about the topic being discussed and to have accurate information. Nurses should convey confidence and certainty in what they are saying, while being able to acknowledge their limitations (e.g., “I don’t know the answer to that, but I will find out”).

Humor

Humor can be a positive and powerful tool in the nurse–patient relationship, but it must be used with care. Humor can be used to help patients adjust to difficult and painful situations. The physical act of laughter can provide an emotional and physical release, reducing tension by providing a different perspective and promoting a sense of well-being. However, in using humor, it is important to consider the patient’s perception of what is considered funny. Timing is also important. For instance, inappropriate use of humor can serve to minimize patient concerns or anxieties. Although humor and laughter can help reduce stress and anxiety, the feelings of the patient should guide the nurse’s use of humor (Tremayne, 2014).

Nonverbal Communication

Nonverbal communication is sometimes called *body language*. It includes gestures, body movements, use of touch, and physical appearance, including adornment. Nonverbal communication often conveys more about what an individual is feeling than what the person actually says, because nonverbal behavior is controlled less consciously than verbal behavior (**Figure 38-3** »). Nonverbal communication can either reinforce or contradict what is said verbally. For example, if a nurse says to a patient, “I’d be happy to sit here and talk to you for a while,” yet glances at the door every few seconds, the nurse’s actions contradict the verbal message. The patient is more likely to believe the nonverbal behavior, which conveys “I am very busy and need to leave.” By contrast, when the nurse enters the patient’s room and finds the patient crying, if the nurse pulls a chair close to the bed and says quietly, “I can see how upset you are, tell me what is bothering you,” the nurse conveys the

Figure 38-3 » Nonverbal communication sometimes conveys meaning more effectively than words. This patient is clearly receptive to the healthcare provider’s message.

message that the nurse cares and has the time and willingness to listen to the patient.

Observing and interpreting a patient's nonverbal behavior is an essential skill that nurses must develop. The efficient observation of nonverbal behavior requires a systematic assessment of the individual's overall physical appearance, posture, gait, facial expressions, and gestures.

Patients who have altered thought processes, such as patients with schizophrenia or dementia, may experience times when expressing themselves verbally is difficult or impossible. During these times, the nurse needs to be able to interpret the feeling or emotion that the patient is expressing nonverbally. An attentive nurse who clarifies observations very often portrays caring and acceptance to the patient. This can be a beginning for establishing a trusting relationship between the nurse and the patient, even for patients who have difficulty communicating appropriately.

Patients who are on the autism spectrum will likely have difficulty understanding nonverbal communication. Many individuals with autism find eye contact difficult, so they avoid it when communicating. When a nurse is speaking to a patient with autism, the nurse's communications should be direct and specific. The nurse should select words carefully, keeping in mind that the patient may not understand any nonverbal messages that may be communicated along with the words. It is critical for nurses to assess patients' communication abilities and communicate in ways that are most likely to result in successful communication with the patient.

Nonverbal communication varies widely among cultures. Even for behaviors such as smiling and handshaking, cultures differ. For example, many people feel that smiling and handshaking are an integral part of an interaction and essential to establishing trust. The same behavior might be perceived by others as insolent and frivolous. Refer to the module on Culture and Diversity for more information on cultural differences.

The nurse cannot always be sure of the correct interpretation of feelings that have been expressed nonverbally. The same feeling can be expressed nonverbally in more than one way, even within the same cultural group. For example, anger may be communicated by aggressive or excessive body motion, or it may be communicated by frozen stillness. In some cultures, a smile may be used to conceal anger. Therefore, the interpretation of such observations requires validation with the patient. For example, the nurse might say, "You look as though you have been crying. Is something upsetting you?"

Personal Appearance

Clothing and accessories can be sources of information about an individual. Although choice of apparel is highly personal, it may convey social and financial status, culture, religion, group association, and self-concept (**Figure 38-4**). Charms and amulets may be worn for decorative or for health protection purposes. When the symbolic meaning of an object is unfamiliar, the nurse can inquire about the object's significance. This may foster rapport with the patient and help the nurse gain a better understanding of the patient's beliefs.

How an individual dresses is often an indicator of how the person feels. Someone who is ill may not have the energy or the desire to maintain his normal level of grooming. When

Figure 38-4 Women who are Muslims may wear a headscarf as part of their hijab (proper clothing) to preserve their modesty. Muslim women may wear the hijab to reflect their devotion to God or as a means to express their Muslim identity. Not all Muslim women wear headscarves; many choose not to veil. In many American families who practice Islam, it is the woman's choice whether to wear a hijab (Arabs in America, n.d.).

someone known for immaculate grooming becomes lax about appearance, the nurse may suspect a loss of self-esteem, depression, or a physical illness. The nurse must validate these observed nonverbal data by asking the patient about them. For acutely ill patients in hospital or home care settings, a change in grooming habits or a desire to take a shower and dress may signal that the patient is feeling better.

Posture and Gait

The ways in which individuals walk and carry themselves are often reliable indicators of self-concept, current mood, and health. Erect posture and an active, purposeful stride suggest a feeling of well-being. Slouched posture and a slow, shuffling gait suggest depression or physical discomfort. Tense posture and a rapid, determined gait suggest anxiety or anger. The posture of individuals when they are sitting or lying can also indicate feelings or mood. Again, the nurse clarifies the meaning of the observed behavior by describing to the patient what the nurse sees and then asking what it means or whether the nurse's interpretation is correct. For example, "You look like it really hurts you to move. I'm wondering how your pain is and if you might need something to make you more comfortable?"

Facial Expression

No part of the body is as expressive as the face (see **Figure 38-5**). Feelings of surprise, fear, anger, disgust, happiness, and sadness can be conveyed by facial expressions. Although the face may express the person's genuine emotions, it is also possible to control these muscles so the emotion expressed does not reflect what the person is feeling. When the message is not clear, it is important to get feedback to be sure of the intent of the expression. No single expression can be interpreted accurately without considering other reinforcing physical cues, the setting in which the expression

Source: Fuse/Corbis/Getty Images.

Figure 38-5 >> The nurse's facial expression communicates warmth and caring.

occurs, the expression of others in the same setting, and the cultural background of the patient.

Nurses need to be aware of their own expressions and what they are communicating to others. Patients are quick to notice a nurse's facial expression, particularly when the patient feels unsure or uncomfortable. The patient who questions the nurse about a feared diagnostic result will watch whether the nurse maintains eye contact or looks away when answering. The patient who has had disfiguring surgery will examine the nurse's face for signs of disgust. It is impossible to control all facial expressions, but the nurse must learn to control expressions of feelings such as fear or disgust in some circumstances.

Eye contact is another essential element of facial communication. In many cultures, mutual eye contact acknowledges recognition of the other person and a willingness to maintain communication. (See the module on Culture and Diversity.) In other cultures, direct eye contact is considered impolite. Often an individual initiates contact with another person with a glance, capturing the person's attention prior to communicating. However, a patient who averts his eyes may be signaling embarrassment or that the patient views the nature of the contact as threatening.

Gestures

Hand and body gestures may emphasize and clarify the spoken word, or they may occur without words to indicate a particular feeling or to give a sign. A father awaiting information about his daughter in surgery may wring his hands, tap his foot, pick at his nails, or pace back and forth. A gesture may indicate the size or shape of an object. Some gestures, such as waving goodbye or motioning to someone to have a seat, have relatively universal meanings. Other gestures, however, are culture specific. The Anglo American gesture meaning "shoo" or "go away" means "come here" or "come back" in some Asian cultures. In the Hmong culture, it is considered rude to point at something with your toe.

For individuals with special communication problems, such as those with hearing impairments, the hands are central

Focus on Diversity and Culture

Nonverbal Communication

Language barriers and differing cultural values create the most evident communication issues when working with patients from backgrounds different from that of the nurse. Nonverbal communication, however, presents an equally complicated set of issues. Just as languages and accents vary across the world, nonverbal communication patterns vary across cultures. Standards for personal space also vary widely by culture (Management Sciences for Health, 2016).

Every culture interprets gestures and other modes of nonverbal communication differently, so exercise caution when working with patients from cultures with which you are unfamiliar. This is particularly true when it comes to the use of therapeutic touch. Many cultures have specific rules or practices regarding the use of touch, especially between individuals of different genders (Andrews & Boyle, 2016). When working with a patient from another culture, always follow the patient's lead and do not be afraid to ask, clarify, and validate the meaning of a gesture or nonverbal response. Use hand and arm gestures with great caution, be careful in interpreting facial expressions, and do not force a patient to make eye contact (Andrews & Boyle, 2016; Vermont Department of Health, n.d.).

to communication. Many individuals who are deaf learn sign language, in which the hands are used along with facial expressions and other body language to form expressions with accepted meanings. Similarly, individuals who are unable to reply verbally may be able to communicate using their hands. For example, the patient who is intubated may be able to raise an index finger once for "yes" and twice for "no." Other signals can often be devised by the patient and the nurse to denote various meanings.

Electronic Communication

Nurses are increasingly using electronic communication media such as email, social media, and text messaging to communicate with patients, other nurses, other departments in their employment setting, and resources outside the employment setting. It is important for nurses to follow their agency's guidelines for the use of electronic communication and to understand the advantages and disadvantages of these media.

Advantages

Electronic communication has many advantages. As Kern and colleagues (2013) note, among organizations adopting electronic communication, researchers discovered that "changing clinical workflows to allow documentation into structured fields had a large effect on accuracy of electronic reporting, enabling corrections of rates of recommended care."

The use of email between providers and patients is becoming increasingly popular. The advantages of one-to-one email communication between nurses and patients are numerous, from email's instantaneous nature to the fact that email addresses tend to change less frequently than residential addresses. Additional benefits of email include increased

efficiency, strengthened patient-provider communications, and informed decision making. Mass emailing provides still more benefits to healthcare providers, including the ability to automatically send condition-specific and stage-specific messages related to patients' diagnoses. Some healthcare facilities provide information to their patients on how to reach specified staff members by email. This improves communication and continuity of patient care.

Social networks such as Facebook and Twitter are less commonly used in healthcare, but they represent an important opportunity for the distribution of less critical health information. Nurses can use social networks to connect with colleagues worldwide for continuous learning through organizations such as the American Nurses Association. Posts on hospital Facebook and Twitter pages can provide followers with helpful information about community events such as health fairs or reminders about influenza vaccinations. During natural disasters, emergency management personnel and healthcare facilities may use social media as an additional method for sharing critically important information (such as evacuation orders and the location of shelters or medical care facilities).

Text messaging is another new frontier in electronic communication for healthcare providers, and it offers the benefits of convenience, ubiquity, immediacy, monitoring of symptoms, dissemination of emergency alerts, and multimedia capability. In communicating with patients, text messaging has been useful for disseminating public service announcements. Between nurses and other healthcare providers, text messaging can provide a convenient and low-cost means of electronic communication.

Disadvantages

The primary disadvantage of electronic communications media is the risk to patient confidentiality. The Health Insurance Portability and Accountability Act (HIPAA) requires organizations to apply "reasonable and appropriate safeguards" when emailing protected health information (PHI). Each healthcare agency needs to have an email encryption system to ensure security. An agency may use its own system or outsource an encryption service. Other disadvantages of email include problems incorporating electronic communications with patients into the electronic medical record and dangers that can arise if a provider overlooks a critical email communication from a patient.

Another disadvantage is one of socioeconomic factors. Not everyone has a computer or a cell phone capable of accessing the internet. And even if internet access is possible, not everyone has the necessary computer skills. Email and social media may enhance communication with some patients, but others will not have access to it at all. Alternative forms of communication will be needed for patients who have limited access to or limited abilities with using the internet.

The major drawbacks of text messaging in a healthcare context are related to its strengths of ubiquity and instantaneousness. Nurses who constantly receive work-related text messages may check their messages at inappropriate times or even use their devices for personal messages while at work. This can prove to be a barrier to effective communications with patients.

When Not to Use Electronic Communications Media

In certain situations, the use of electronic communication should be avoided:

- When the information is urgent and the patient's health could be in jeopardy if the patient doesn't read the message immediately
- When the information is highly confidential (e.g., HIV status, mental health, chemical dependency)
- When lab data are abnormal. If the information is likely to be confusing and could prompt many questions, it is better to either see or telephone the patient.

Other Guidelines

Agencies usually develop standards and guidelines for the use of electronic media in healthcare. It is important for nurses to know their employer's guidelines regarding the use of electronic media to communicate with patients. In the case of email, the patient is asked to sign an email consent form. This form provides information about the risks of email and authorizes the health agency to communicate with the patient at a specified email address. The website of the National Council of State Boards of Nursing also provides guidance to nurses on the use of social and electronic media in healthcare.

The nurse should indicate in the subject line that the email is confidential. It may also be prudent to include a disclaimer in the email stating that the message is to be read only by the person to whom it is addressed and that no one else is authorized to read the message. In addition, the disclaimer should state that if the email is sent to anyone else by mistake, the recipient should contact the sender.

Information sent to a patient via email is considered part of the patient's medical record. Therefore, a copy of the email needs to be put in the patient's chart. Emails, like other documentation in the patient's record, may be used as evidence during litigation. Rules for written communication (see the next section) also apply to email communication.

Email is another form of communication that can enhance effective relationships with patients. It is not, however, a substitute for effective in-person communication. The nurse needs to use professional judgment about what form(s) of communication will best meet the patient's health needs.

Written Communication

Written communication can be considered a form of verbal communication. Examples of forms of written communication include notes, letters, email messages, and text messages. Written communication has some limitations. For example, it lacks the nonverbal cues that accompany verbal communication. For example, you may receive a text message from a friend that says, "GET OUT OF HERE!!" Without an understanding of context, this message could be interpreted as shock and disbelief at something you told your friend, or anger and the wish for you to vacate the friend's life, or a request to be left alone. Only by hearing tone of voice and seeing body language can context be relayed. As a result, rules for written communication differ from rules for other forms of communicating.

Nurses have many requirements as well as opportunities for written communication. The most common form of written communication in nursing is the notes nurses make in the medical record about a patient's status, which are discussed in Exemplar 38.C on documentation. Nurses also write discharge instructions for patients and their families, memos to nursing colleagues and other healthcare professionals, and patient educational materials. Nurse-managers write employee evaluations, policies and procedures, and other communications to administrators, colleagues, and nursing staff. An important consideration in written communication is that decoding often occurs when the writer is not present and may occur long after the document is written. Therefore, clarity is important because it may not be possible to ask questions or process areas of confusion.

Characteristics of Effective Written Communication

In addition to simplicity, brevity, clarity, relevance, credibility, and humor (characteristics of effective oral communication), written communication must contain the following:

1. **Appropriate language and terminology.** Language and terminology must be appropriate for the developmental age, education and reading level, and culture of the reader. Health education materials written for children should be different from materials written for adults. For individuals whose primary language is not English, it may be more effective to have written

materials translated into their primary language by a professional translator. Extensive use of illustrations can also aid in communication. Appropriate lay terminology may be substituted for medical terminology; for example, *high blood pressure* may be used instead of *hypertension*. National standards for culturally and linguistically appropriate services in health and healthcare (CLAS) are listed in **Box 38–1**.

» **Stay Current:** For more information regarding the CLAS standards, go to <https://www.thinkculturalhealth.hhs.gov/pdfs/EnhancedCLASStandardsBlueprint.pdf>.

2. **Correct grammar, spelling, and punctuation.** The use of correct grammar, spelling, and punctuation provides clarity for the reader. Misspelled words, misplaced punctuation, and incorrect grammar can change the intended meaning, cause confusion, and undermine the reader's confidence in the sender.
3. **Logical organization.** Written materials are well organized when they are logical and easy for readers to follow. Simple and foundational information is usually provided first, followed by more complex information. Using examples can also assist readers.
4. **Appropriate use and citation of resources.** Information taken from other sources must always be credited to the original source. Failure to reference work taken from another writer is called plagiarism, is considered unethical, and may violate copyright laws. Various styles of referencing are in use, including the Modern

Box 38–1

National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care (CLAS)

Standard 1: Provide effective, equitable, understandable, and respectful quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs.

Standard 2: Advance and sustain organizational governance and leadership that promotes CLAS and health equity through policy, practices, and allocated resources.

Standard 3: Recruit, promote, and support a culturally and linguistically diverse governance, leadership, and workforce that are responsive to the population in the service area.

Standard 4: Educate and train governance, leadership, and workforce in culturally and linguistically appropriate policies and practices on an ongoing basis.

Standard 5: Offer language assistance to individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all health care and services.

Standard 6: Inform all individuals of the availability of language assistance services clearly and in their preferred language, verbally and in writing.

Standard 7: Ensure the competence of individuals providing language assistance, recognizing that the use of untrained individuals and/or minors as interpreters should be avoided.

Standard 8: Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations in the service area.

Standard 9: Establish culturally and linguistically appropriate goals, policies, and management accountability, and infuse them throughout the organization's planning and operations.

Standard 10: Conduct ongoing assessments of the organization's CLAS-related activities and integrate CLAS-related measures into measurement and continuous quality improvement activities.

Standard 11: Collect and maintain accurate and reliable demographic data to monitor and evaluate the impact of CLAS on health equity and outcomes and to inform service delivery.

Standard 12: Conduct regular assessments of community health assets and needs and use the results to plan and implement services that respond to the cultural and linguistic diversity of populations in the service area.

Standard 13: Partner with the community to design, implement, and evaluate policies, practices, and services to ensure cultural and linguistic appropriateness.

Standard 14: Create conflict and grievance resolution processes that are culturally and linguistically appropriate to identify, prevent, and resolve conflicts or complaints.

Standard 15: Communicate the organization's progress in implementing and sustaining CLAS to all stakeholders, constituents, and the general public.

Concepts Related to Communication

Communication is a concept that relates to every healthcare concept and is used in every healthcare setting. Communication is the cornerstone of patient care, and nurses, along with all healthcare providers, must be mindful of their communication techniques when providing care, regardless of setting. Communication binds healthcare workers, patients, and institutions together and is the means through which nurses provide both hospital-based and community-based care. Nurses should keep in mind the patient's needs and limitations and always take care to use technical terms and medical terminology judiciously during communication (Kourkouta & Papathanasiou, 2014). Listening is an essential component in nursing communication, and it is the foundation of responsible nursing practice. When listening, nurses should assess both the verbal and nonverbal statements of the patient. By being attentive to unspoken needs, nurses can enhance nursing diagnoses and the quality of care.

One of the most important components of providing effective communication in real-world nursing practice is tailoring communication efforts to the particular situation of the patient. Patients will vary dramatically in their ability to communicate and listen effectively at the time of treatment. Physiologic illness, cognitive impairment, substance abuse, mental illness, the emotional context of the healthcare encounter, and linguistic and cultural differences are all factors that can affect a patient's ability to communicate with the healthcare team. In all cases, the nurse is responsible for ensuring successful communication and for advocating for patients who are unable to advocate for themselves. The Concepts Related to Communication feature provides examples of some of the many concepts integral to communication. They are presented in alphabetical order.

Factors Influencing the Communication Process

Many factors influence the communication process. Some of these are development, gender, sociocultural characteristics, values and perceptions, personal space, territoriality, roles and relationships, environment, congruence, and attitudes.

Development

As individuals grow and develop, language and communication skills develop through various stages. It is important for the nurse to understand the developmental processes related to speech, language, and communication skills. Knowledge of the patient's developmental stage enables the nurse to select appropriate communication strategies. For example, when communicating with infants and toddlers whose language skills are not well developed, the nurse may rely more on the child's nonverbal communications to assess comfort and pain. The nurse may hold the child and use touch to provide comfort and demonstrate caring. For

older children, the nurse may use pictures as an adjunct to verbal language to communicate. For adolescents and adults, the nurse is more able to rely on verbal language for communication. With older adults, physical changes associated with the aging process may affect communication. For example, it may be more effective to use visual communication methods for patients who have hearing impairments or aural communication methods for patients who have visual impairments. Also, intellectual processes develop across the lifespan as individuals acquire knowledge and experience. The knowledge and experiences that individuals have will influence their understanding and acceptance of transmitted information and feelings. The Lifespan Considerations section discusses some aspects of communicating with children as they grow from infancy to adolescence.

Gender

From an early age, females and males may exhibit differences in language development and communication tendencies. Examples often cited include the tendency of females to make requests and males to make demands, of males to address issues more directly and females to be more active listeners, often using statements that encourage a response. **Active listening**, also known as *attentive* or *mindful listening*, involves fully concentrating on both the content and emotion of a person's message, rather than just passively hearing the words a person says. (For more information on this topic, see Exemplar 38.B: Therapeutic Communication.) Although it has long been believed that these perceived differences result from psychosocial development, more recent research indicates that language development proceeds differently in girls than boys, indicating that both neuronal factors and psychosocial factors influence language and communication differences (Kaushanskaja, Gross, & Buac, 2013).

When working with patients or colleagues, nurses should be aware that men and women might interpret the same communication differently. Thus, nurses should always work to assess the ways in which a patient's or colleague's communication is gendered. Maintaining an understanding of the ways in which people communicate differently because of their socialization allows the nurse to respond accordingly.

An emerging area of awareness in healthcare communities is communicating with transgender individuals and individuals who identify as nonbinary or gender nonconforming (identifying as neither male nor female). In everyone, gender identity (how one sees oneself), gender expression (the outward expression of an individual's sense of maleness or femaleness), biological sex (one's anatomy), and sexual attraction (to whom one is sexually attracted) are distinct, and each element of identity can be well-defined or ambiguous. Transgender individuals who have not had sex reassignment surgery have a gender identity that may not align with their biological sex, and therefore, their name or appearance may not "match" their stated (or legal) sex. The nurse should always use a patient's preferred name and pronoun (whether "he," "she," "them," or something else) and guard the patient's privacy. By protecting the privacy and personal expression of transgender and nonbinary individuals and treating them with respect, nurses can reduce undue stress, promote the therapeutic

Concepts Related to Communication

CONCEPT	RELATIONSHIP TO COMMUNICATION	NURSING IMPLICATIONS
Advocacy	Communication among nurses, patients, and physicians is a key component of effective healthcare. In addition to communication with patients, nurses directly or indirectly influence physician–patient communications.	<ul style="list-style-type: none"> Assess what the healthcare provider has told the patient regarding the patient’s condition. Encourage the patient to clarify the understanding with the healthcare provider. Help the patient identify and access high-quality sources of healthcare information. Always advocate for the best interests of the patient and the patient’s expressed wishes.
Comfort	Pain → communication ability. Impaired communication may ↓ ability to report pain.	<ul style="list-style-type: none"> Take patient’s report of pain levels seriously. Assess for nonverbal signs of pain such as wincing and guarding. Communicate equally with patients across the lifespan. Use a pain management scale such as a numeric rating scale or the FACES pain rating scale that is appropriate for the patient’s age and ability to communicate. Investigate palliative care options for patients at the end of life.
Grief and Loss	Grief or loss can adversely affect the way in which an individual communicates. Not only does the person experiencing the loss have trouble communicating needs to others, but others often do not know how to communicate their condolences to those who have experienced a loss. Cultural differences can exacerbate communication issues.	<ul style="list-style-type: none"> Determine the effects of the loss on the patient. If the patient is grieving the loss of a primary caregiver or a spouse who provided financially for the patient, the patient may have a number of immediate needs. Consider the stages of grief when communicating with patients. Consider the cultural background of the patient and family related to expressions of grief and loss.
Intracranial Regulation	Impaired intracranial regulation → impaired communication. Traumatic brain injury → difficulty with word finding, sentence formation, and expression. Patients with severe increased intracranial pressure may enter a coma state.	<ul style="list-style-type: none"> Recognize the communication difficulties caused by traumatic brain injuries early and respond appropriately. Help the patient with cognitive and/or physical limitations find an appropriate therapist to help them regain lost abilities. If patients have difficulty expressing their thoughts, calmly help them find ways of communicating.
Mood and Affect	A diagnosis of mental illness ↑ likelihood patient will experience discrimination/stigma, may ↑ reluctance to trust healthcare personnel. In addition, healthcare providers may miss signs that these patients are suffering from these disorders.	<ul style="list-style-type: none"> Be aware that people of all ages suffer from mental and psychiatric disorders. Do not assume that someone does not have one of these conditions because of their physical appearance. Screen patients for depression or other psychiatric illness by asking open-ended questions with empathy. Research medical records for histories of mental illness and cognitive issues and shape communication appropriately. Be consistent and predictable in your nursing practice and communication.
Oxygenation	Decreased O ₂ → hypoxemia → decreased level of consciousness (LOC) → decreased ability to communicate verbally (due to shortness of breath and LOC) and nonverbally (due to decreased LOC).	<ul style="list-style-type: none"> Position patient in Fowler or semi-Fowler position as indicated to promote ease of breathing. Administer medications and supplemental oxygen as ordered. Consider other methods of communication for the patient (e.g., a tablet, a family member).
Safety	Impaired communication ↑ risk for illness and injury.	<ul style="list-style-type: none"> Create a supportive environment that promotes communication and safety. Introduce opportunities for the patient to communicate needs and concerns. Be tactful and avoid abrupt, offensive, and accusatory statements. Maintain a nonthreatening approach and validate cooperation. Listen to the concerns of other members of the healthcare team. Apologize when needed. Agree when possible. Encourage the team to follow national standards.

relationship, and help these individuals feel safe in health-care contexts (Booth, 2014).

Sociocultural Characteristics

Culture, education, and economic level can influence communication. Nonverbal communication characteristics such as body language, eye contact, and touch are influenced by cultural beliefs about appropriate communication behavior. Some cultures may believe that direct eye contact is disrespectful, whereas other cultures believe that direct eye contact shows trustworthiness. In some cultures touch would be appropriate to communicate caring and concern, but in other cultures physical touch would be offensive. Verbal communication may be difficult for the receiver whose primary language is not that of the sender. More information about the influence of culture on communication can be found in the module on Culture and Diversity.

An individual's level of education may affect the extent of that individual's vocabulary or ability to read written communication. Economic level may affect an individual's ability to access written or electronic communication, including email and the internet.

Values and Perceptions

Values are the standards that influence behavior, and **perceptions** are the personal views of an event. Because each person has unique personality traits, values, and life experiences, each will perceive and interpret messages and experiences differently. For example, if a nurse draws the curtains around a crying woman and leaves her alone, the woman may interpret this as either "The nurse thinks that I will upset others and that I shouldn't cry" or "The nurse respects my need to be alone." It is important for the nurse to be aware of a patient's values and to validate or correct perceptions to avoid creating barriers in the nurse-patient relationship.

Personal Space

Personal space is the distance individuals prefer to keep between themselves and others during interactions. **Proxemics** is the study of distance between individuals who are interacting. Many living in North America use definite distances in various interpersonal relationships, along with specific voice tones and body language. Communication thus alters in accordance with four distances in this culture, each with a close and a far phase (Samovar et al., 2016):

1. **Intimate:** touching to $1\frac{1}{2}$ feet
2. **Personal:** $1\frac{1}{2}$ –4 feet
3. **Social:** 4–12 feet
4. **Public:** 12–15 feet

Intimate distance communication is characterized by body contact, heightened sensations of body heat and smell, and vocalizations that are low. Vision is intense, restricted to a small body part, and may be distorted. Nurses frequently use intimate distance. Examples include cuddling a baby, positioning a patient, observing an incision, and giving an injection. It is a natural protective instinct for individuals to maintain a certain amount of space immediately around them. That amount varies with individuals and cultures. When someone who wants to communicate moves too close,

the receiver automatically steps back a pace or two. In their therapeutic roles, nurses often are required to violate this personal space. However, it is important for the nurse to know when this will occur and to inform the patient in advance.

Personal distance is less overwhelming than intimate distance. At personal distance, voice tones are moderate, and body heat and smell are less noticeable. Physical contact such as a handshake or touching a shoulder is possible. Because more of the individual is experienced at a personal distance, nonverbal behaviors such as body stance or full facial expressions are seen with less distortion. Much communication between nurses and patients occurs at this distance. Examples include when the nurse is sitting with a patient, giving medications, or establishing an intravenous infusion. Communication at a close personal distance can convey involvement by facilitating the sharing of thoughts and feelings. On the other hand, it can also create tension if the distance encroaches on the other person's personal space (**Figure 38-6**). At the outer extreme of 4 feet, however, less involvement is conveyed. Bantering and some social conversations usually take place at this distance.

Social distance is characterized by a clear visual perception of the whole person. Body heat and odor are imperceptible, eye contact is increased, and vocalizations are loud enough to be overheard by others. Communication is therefore more formal and is limited to seeing and hearing. The person is protected and out of reach of touch or personal sharing of thoughts or feelings. Social distance allows more activity and movement back and forth. It is expedient for communicating with several individuals at the same time or within a short time. Examples include when the nurse makes rounds or waves a greeting to someone. Social distance is important in accomplishing the business of the day; however, it is frequently misused. For example, the nurse who stands in the doorway and asks a patient, "How are you today?" will receive a more noncommittal reply than the nurse who moves to a personal distance to make the same inquiry.

Public distance requires loud, clear vocalizations with careful enunciation. Although the faces and forms of people

Figure 38-6 Personal space influences communication in social and professional interactions. Encroachment into another individual's personal space may create tension.

are visible at public distance, individuality is lost. Instead, the perception is of the group of people or the community.

Territoriality

Territoriality is a concept of the space and things that an individual considers as belonging to the self. Territories marked off by individuals may be visible to others. For example, patients in a hospital often consider their territory as bounded by the curtains around the bed unit or by the walls of a private room. All healthcare workers must recognize this human tendency to claim territory. Patients often feel the need to defend their territory when it is invaded by others. For example, when a nurse removes a chair to use at another bed, the nurse has inadvertently violated the territoriality of the patient whose chair was removed. The nurse needs to obtain permission from the patient to remove, rearrange, or borrow objects in the patient's hospital area.

Roles and Relationships

The roles and the relationships between sender and receiver affect the communication process. Roles such as nursing student and instructor, patient and primary care provider, or parent and child affect content and responses in the communication process. Choice of words, sentence structure, message content and channel, body language, and tone of voice vary considerably from role to role. In addition, the specific relationship between the communicators is significant. The nurse who is meeting with a patient for the first time communicates differently from the nurse who has previously developed a relationship with that patient. The nurse may choose a more informal or comfortable stance when communicating with patients or colleagues and a more formal stance when communicating with physicians or administrators. The length of the relationship may also affect communication. For example, the nurse may use more formal language and stance when meeting a patient or colleague for the first time and a more relaxed posture when interacting with those whom the nurse has an established relationship.

Environment

Individuals usually communicate most effectively in a comfortable environment. Environmental distractions such as temperature extremes, excessive noise, and poor ventilation can impair or distort communication. Also, lack of privacy may interfere with a patient's communication about matters the patient considers private or personal. For example, a patient who is worried about the ability of his wife to care for him after discharge from the hospital may not wish to discuss this concern with a nurse within hearing distance of other patients, staff, or his wife.

Congruence

Patients more readily trust the nurse when they perceive the nurse's communication as congruent. This also helps prevent miscommunication. Congruence between verbal and nonverbal expression is easily observed by both the nurse and patient. Nurses are taught to assess patients, but patients are often just as adept at reading a nurse's expression or body language. If there is any incongruence, the true meaning is usually conveyed by the sender's body language. For example, when teaching a patient how to care for a colostomy, the

nurse might say, "You won't have any problem with this." However, if the nurse looks worried or disgusted while saying this, the patient is less likely to trust the nurse's words.

Nurses must strive to improve their nonverbal communication skills. One strategy is to refrain from indiscriminate use of nonverbal gestures, such as the overuse of smiling or nodding the head, because this can cause the patient to doubt the nurse's sincerity. Another strategy is to convey a relaxed attitude, rather than a distressed attitude. Being relaxed makes it easier for patients to feel at ease around the nurse.

Interpersonal Attitudes

Attitudes convey beliefs, thoughts, and feelings about people and events. Attitudes are communicated convincingly and rapidly to others. Attitudes such as caring, warmth, respect, and acceptance facilitate communication, whereas condescension, lack of interest, and coldness inhibit communication.

Kourkouta and Papathanasiou (2014) found that effective nursing communication is significantly related to patient satisfaction. When nurses communicate (both verbally and nonverbally) warmth, positivity, energy, and capability, patients express greater satisfaction with both competence and interpersonal care. Caring involves giving feelings, thoughts, skill, and knowledge. It requires psychological energy and poses the risk of gaining little in return; yet by caring, both nurses and patients usually reap the benefits of greater communication and understanding.

Respect, an attitude that emphasizes the other person's worth and individuality, and *civility*, the use of courtesy in communication, are two qualities that promote effective communication. Respect conveys that the person's hopes and feelings are special and unique, even though they are similar to those of others in many ways. Being too different can be isolating and threatening. The use of civility shows respect to the individual with whom the nurse is communicating.

Healthcare providers may unknowingly show disrespect or incivility by using speech that they believe shows caring but that the patient perceives as demeaning or patronizing. This can happen in settings that provide healthcare to older adults and/or individuals with obvious physical or mental disabilities. **Elderspeak** is a style of speech similar to baby talk that sends the message to older adults that they are dependent and incompetent. It does not communicate respect. Many healthcare providers are not aware that they use elderspeak or that it can have negative meanings to the patient. The characteristics of elderspeak include use of inappropriate terms of endearment (such as "honey" or "dear"), plural pronouns (e.g., "Are we having a good day?"), tag questions, and slow, loud speech. Tag questions are short statements followed by a mini-question, such as "You feel better now, don't you?" Tag questions and other types of elderspeak should not be used with any age group. Alternative strategies to elderspeak include:

- Instead of using diminutives or terms of endearment, refer to and call the patient by full name (e.g., Ms. Applewhite) or preferred name.
- Instead of using inappropriate plural pronouns such as "we," always speak to the patient by using "you."
- Avoid tagging questions with words that would cause the patient to think that you are leading him or her to answer in a certain way. Instead, ask the question directly.

- Avoid the use of baby talk, as this is demeaning to the patient. Always address patients as the adults that they are.

Acceptance emphasizes neither approval nor disapproval. The nurse willingly receives the patient's honest feelings. An accepting attitude allows patients to express personal feelings freely and to be themselves. The nurse may need to restrict acceptance in situations in which patients' behaviors are harmful to themselves or to others. Helping the patient find appropriate behaviors for feelings is often part of patient teaching.

Barriers to Communication

Just as there are characteristics of effective communication, there are identified barriers to effective communication. Nurses need to be cognizant of these barriers and avoid them. Nurses also need to recognize the barriers when they occur and change to more effective means of communication. Failing to listen, improperly decoding the patient's intended message, and placing the nurse's needs above the patient's needs are major barriers to communication. Additional barriers to effective communication are given in **Table 38-1** >>.

TABLE 38-1 Barriers to Communication

Technique	Description	Examples
Stereotyping	Offering generalized and oversimplified beliefs about groups of individuals that are based on experiences too limited to be valid. These responses categorize patients and negate their uniqueness as individuals.	"Two-year-olds are brats." "Women are complainers." "Men don't cry." "Most people don't have any pain after this type of surgery."
Agreeing and disagreeing	Similar to judgmental responses, agreeing and disagreeing imply that the patient is either right or wrong and that the nurse is in a position to judge this. These responses deter patients from thinking through their position and may cause a patient to become defensive.	<i>Patient:</i> "I don't think Dr. Broad is a very good doctor. He doesn't seem interested in his patients." <i>Nurse:</i> "Dr. Broad is head of the department of surgery and is an excellent surgeon."
Being defensive	Attempting to protect an individual or healthcare service from negative comments. These responses prevent the patient from expressing true concerns. The nurse is saying, "You have no right to complain." Defensive responses protect the nurse from admitting weaknesses in the healthcare services, including personal weaknesses.	<i>Patient:</i> "Those night nurses must just sit around and talk all night. They didn't answer my light for over an hour." <i>Nurse:</i> "I'll have you know we literally run around on nights. You're not the only patient, you know."
Challenging	Giving a response that makes patients prove their statement or point of view. These responses indicate that the nurse is failing to consider the patient's feelings, making the patient feel it necessary to defend a position.	<i>Patient:</i> "I felt nauseated after that red pill." <i>Nurse:</i> "Surely you don't think I gave you the wrong pill?" <i>Patient:</i> "I feel as if I am dying." <i>Nurse:</i> "How can you feel that way when your pulse is 60?" <i>Patient:</i> "I believe my husband doesn't love me." <i>Nurse:</i> "You can't say that. Why, he visits you every day."
Probing	Asking for information chiefly out of curiosity rather than with the intent to assist the patient. These responses are considered prying and violate the patient's privacy. Asking "why" is often probing and places the patient in a defensive position.	<i>Nurse:</i> "Tell me about how you were sexually abused when you were a teenager." <i>Patient:</i> "I didn't ask the doctor about that when he was here." <i>Nurse:</i> "Why didn't you?"
Testing	Asking questions that make the patient admit to something. These responses permit the patient only limited answers and often meet the nurse's need rather than the patient's.	"Who do you think you are?" (forces the individual to admit to a lower status) "Do you think I am not busy?" (forces the patient to admit that the nurse really is busy)
Rejecting	Refusing to discuss certain topics with the patient. These responses often make patients feel that the nurse is rejecting not only their communication but also the patients themselves.	"I don't want to discuss that. Let's talk about. . . ." "Let's discuss other areas of interest to you rather than the two problems you keep mentioning." "I can't talk now. I'm on my way for coffee break."
Changing topics and subjects	Directing the communication into areas of self-interest rather than considering the patient's concerns is often a self-protective response to a topic that causes the nurse anxiety. These responses imply that what the nurse considers important will be discussed and that patients should not discuss certain topics.	<i>Patient:</i> "I'm separated from my wife. Do you think I can start sleeping with other women?" <i>Nurse:</i> "I see that you're 36 and that you like gardening. I bet you're looking forward to summer."
Unwarranted or false reassurance	Using clichés or comforting statements of advice as a means to reassure the patient. These responses block the fears, feelings, and other thoughts of the patient.	"You'll feel better soon." "I'm sure everything will turn out all right." "Don't worry."
Passing judgment	Giving opinions and approving or disapproving responses, moralizing, or imposing one's own values. These responses imply that the patient must think as the nurse thinks, fostering patient dependence.	"That's good (bad)." "You shouldn't do that." "That's not good enough." "What you did was wrong (right)."
Giving common advice	Telling the patient what to do. These responses deny the patient's right to be an equal partner. Note that giving expert advice that is appropriate for the patient's individual situation rather than common advice is therapeutic.	<i>Patient:</i> "Should I move from my home to a nursing home?" <i>Nurse:</i> "If I were you, I'd go to a nursing home where you'll get your meals cooked for you."

Types of Communicators

Different individuals have different ways or styles of communicating. Gender, culture, personality type, and degree of confidence can all play a role in how a nurse communicates with others. Communication is complex and requires that the nurse use a thoughtful process to communicate effectively. Communication style is something that is used daily in both the work and home environments but often is not viewed as important until there is a problem with it.

Individuals tend to express themselves in various ways. **Aggressive communicators** are those who tend to focus on their own needs and become impatient when these needs are not met. **Passive communicators** are those who focus on the needs of others. They often deny themselves any sort of power, which causes them to become frustrated. **Assertive communicators** are those who declare and affirm their opinions. In doing this, however, they respect the rights of others to communicate in the same fashion. The assertive communicator strikes a balance between the aggressive communicator and the passive communicator. It is the assertive communicator who has the most productive communication with others. **Table 38-2** » compares and contrasts the three styles of communicating.

Individuals who use assertive communication express themselves effectively and stand up for their beliefs while respecting the rights of others (Mayo Clinic, 2014). Assertive communicators are honest, direct, and appropriate while being open to ideas and showing concern for the needs of others. They advocate for their patients. Assertive communication promotes patient safety by minimizing miscommunication with colleagues. Failure to communicate can result in negative patient outcomes.

An important characteristic of assertive communication includes the use of “I” statements versus “you” statements. The “you” statement places blame and puts the listener in a defensive position. On the other hand, the “I” statement encourages discussion. For example, a nurse who states “I am concerned about . . .” to a physician will gain the attention of the physician while also giving the message of the importance of working together for the benefit of the patient. Once the nurse has the physician’s attention, it is important for the nurse to be clear, concise, organized, and fully informed when presenting the patient concern.

The passive, submissive communication style often causes rights violations. Individuals who use this style meet the demands and requests of others without regard to their own feelings and needs, as they believe their own feelings are not

important. Some experts believe that individuals who use submissive behaviors or communication styles are insecure and try to maintain their self-esteem by avoiding conflict (e.g., negative criticism and disagreement from others).

Individuals who use aggressive communication assert their legitimate rights and options with little regard or respect for others. Aggressive communication is often perceived as a personal attack by the recipient because aggressive communication humiliates, dominates, controls, or embarrasses the recipient. By lowering the other person’s self-esteem, the person using aggressive communication may feel superior, which helps increase the aggressive communicator’s self-esteem. Aggressive communication takes several different forms, which can include screaming, sarcasm, rudeness, belittling jokes, and direct personal insults.

A nurse’s approach to communication can have far-reaching impact on the quality of patient care delivered. Consider the following case study.

Clinical Example A

You are a nurse who is caring for Shannon Collins, a 41-year-old woman. Mrs. Collins has a standing order for vital signs every 2 hours because her temperature was elevated on admission to the facility. Since admission, Mrs. Collins’s temperature has normalized, and her vital signs have consistently been within normal limits. She tells you that she isn’t sleeping well because the nurses keep coming in and waking her every 2 hours and it takes her almost an hour to fall back to sleep. As a result, she is sleeping in 1-hour intervals and feels extremely sleep deprived. You approach the physician and request that the order be changed to every 4 hours during the day with 6 hours of uninterrupted sleep from midnight to 6:00 a.m. The physician responds by saying, “If she wants to sleep, she’ll have to wait until she goes home. I want vital signs every 2 hours as ordered.”

Critical Thinking Questions

1. Which type of communication style will best serve the needs of the patient? Provide a rationale for your response.
2. What type of response will the nurse have using an aggressive communication style?
3. What type of response will the nurse have using a passive communication style?
4. What type of response will the nurse have using an assertive communication style?

Assertive Communication

The goal of all true professionals is to achieve a mutual respect for boundaries in order to promote the best outcome for everyone involved. Assertive communication allows the

TABLE 38-2 Aggressive, Passive, and Assertive Styles

Aggressive Individuals	Passive Individuals	Assertive Individuals
<ul style="list-style-type: none">■ Have loud, heated arguments■ Are physically violent■ Blame others■ Use name-calling and verbal insults■ Walk out of arguments prior to their resolution■ Are demanding	<ul style="list-style-type: none">■ Conceal their feelings■ Deny anger■ Feel that no one has the right to express anger■ Avoid arguments■ Are noncommittal	<ul style="list-style-type: none">■ Express their feelings without being nasty or overbearing■ Acknowledge emotions■ Stay open to discussion■ Express themselves while giving others that same opportunity■ Use “I” statements to defuse arguments■ Provide reasons and ask for the same in return

nurse to express all ideas in a direct and nonconfrontational manner that promotes the rights of the nurse or the patient while respecting the rights of others to have a different outlook. Assertive communication does not use name-calling, is not judgmental, and does not blame others. It increases the likelihood of creating a win-win result in which both parties walk away feeling that their point of view was heard and understood while reaching a conclusion satisfactory to them both.

Characteristics of assertive communicators include freedom to express themselves, awareness of their own rights, and self-control over strong emotions such as anger, fear, or frustration. Assertive communicators are professional and serve as the best advocate for the patient. Assertive communicators express their opinions but are open to listening to others' points of view. They do not use sarcasm, biting comebacks, or passive-aggressive wounding to promote their superiority. Assertive communicators use body language that is relaxed and open to the words of others. They use a tone of voice that is well modulated with appropriate inflection and avoid raising their voice, whispering, or using aggressive overtones.

An assertive individual receives feedback from others with a willingness to consider both the positive and negative perspectives of the evaluator. Although assertive individuals may not believe everything that is said, they will listen to another individual's opinion without becoming defensive or angry and without attacking the speaker. Seeking clarification is appropriate to be sure that the perception of the message is the same as what the sender intended.

Some individuals may have more trouble accepting positive feedback and will dismiss it or negate it when offered. The assertive individual simply says "Thank you" and considers the value of the positive feedback for later application to similar situations.

Benefits of Assertive Communication

Assertiveness is an effective and professional communication style because it is based on mutual respect. An assertive style improves communication and reduces stress by de-escalating conflict, improving outcomes, and reducing the likelihood of angry encounters.

Techniques for Assertive Communication

Because no one technique works in every situation, the nurse must have an arsenal of strategies to use when faced with a situation requiring assertive communication. These techniques include the following:

- **"I" statements.** Assertive communicators voice their own feelings and wishes based on sound evidence without placing blame or raising the defenses of the individual to whom they are speaking. For example, "I have assessed that Patient A is. . ."
- **Fogging.** Finding some area, no matter how small, on which both parties agree and building from there is a technique that assertive communicators use. In the example of the sleep-deprived patient described previously, both the nurse and the physician can agree that they want to maintain patient safety through careful monitoring of the patient's condition. This gives them a starting point

from which to reach consensus where both can feel patient care has been optimized.

- **Negative assertion.** An assertive communicator can agree with criticism without becoming upset or angry, thus moving the focus of the communication toward the desired goal. This can be particularly important to the nurse when receiving feedback related to the quality of the care the nurse delivers. For example, when the evaluator says, "Although you are very caring, I would like to see you improve your decision-making ability," the nurse may respond, "I could use improvement in my decision-making ability, but I believe the quality of the care I deliver is excellent." This prevents an ongoing debate about something that both parties agree on and allows the communication to move forward regarding the more important topic.
- **Repetition.** When being met with resistance to a request, repeating the request can be useful. However, each time the request is repeated, the power of the words is diminished. This strategy is effective only if the nurse has power within the relationship. For example, suppose the nurse calls the pharmacy to request a newly ordered medication that is to be given within the hour. The pharmacist explains that the pharmacy is very busy, cannot fill the prescription right now, and will not be able to deliver it to the unit for 3–4 hours. The nurse repeats, "I must give this medication within the hour" or "The patient needs the medication within the hour." The effectiveness of this approach may improve if the nurse attempts to find a compromise. The nurse might say, "I need to administer this medication within the hour," to which the pharmacy responds, "I'm sorry, I can't have it to the floor that quickly." The nurse then responds, "The patient needs that medication within the hour. What if I come to the pharmacy so you don't have to deliver it?" This allows for the nurse and the pharmacy to collaborate to reach a mutually effective solution to the problem through compromise.
- **Confidence.** Confidence is essential to assertive communication. A choppy or weak tone of voice implies uncertainty. The nurse should maintain an air of confidence in order to help others see their needs and wants as having merit.
- **Managing nonverbal communication.** Getting too close to the other individual, wagging a finger in someone's face, or glaring at the other person can all counteract assertive words. By maintaining open, assertive body language and keeping a neutral voice, the nurse promotes shared decision making and compromise.
- **Thinking before speaking.** Consider both the choice of words and the tone of voice before speaking. This helps the nurse avoid saying something she will later regret or that will reduce the effectiveness of her communication style.
- **Avoiding apologizing whenever possible.** This is particularly important for women, who have a tendency to say "I'm sorry" even when there is no call for an apology. A woman may say, "I'm sorry, I didn't hear you," or "I'm sorry to bother you, but. . ." An unnecessary apology immediately places the communicator in a somewhat submissive position. Apologies should be given only when warranted.

- **Performing a post-conversation evaluation.** Assertive communicators can continue to improve their skills by reviewing what was said and how the communication might have been handled differently to improve the final outcome. This should be done even when the communication interaction was successful because evaluation of what went well, in contrast to what did not, helps the nurse improve assertive communication skills.

Although some individuals may not prefer or feel comfortable with assertive communication, it is possible for all nurses to become assertive communicators and reach more positive outcomes through practice, self-evaluation, and ongoing efforts to improve their communication approach.

Lifespan Considerations

The ability to communicate is directly related to the development of thought processes, the presence of intact sensory and motor systems, and the extent and nature of an individual's opportunities to practice communication skills. As individuals grow and mature, their communication abilities change markedly.

Communicating with Infants

Infants communicate nonverbally, often in response to bodily sensations rather than in a conscious effort to be expressive. Infants' perceptions are related to sensory stimuli. For example, a gentle voice is soothing, whereas tension and anger displayed around an infant create distress. According to research (Rependa, 2012), infants use two types of nonverbal cues: engagement and disengagement cues. Each type of cue may be expressed in a subtle or direct manner. Disengagement cues include crawling away, crying, or lip compression. Engagement cues include smiling, babbling, and opening hands. Nurses can familiarize themselves with the expressive but nonverbal messages of infants to more effectively communicate with their youngest patients.

Communicating with Toddlers and Preschoolers

As they grow and develop toddlers and young children gain skills in both expressive (i.e., telling others what they feel, think, want, care about) and receptive (hearing and understanding what others are communicating to them) language. Toddlers need time to complete verbalizing their thoughts without interruption. Adults should provide simple responses to questions and straightforward, one-step directions because toddlers have short attention spans. Around the age of 4, children begin to follow two- and three-step directions and become more able to express feelings and sensations. For children at this age, drawing pictures or using pictures and photos to communicate can be helpful in a variety of settings.

Communicating with School-age Children

In interactions with school-age children, it is important to give them opportunities to be expressive, listen openly, and respond honestly, using words and concepts they

understand. Talk to children at their eye level to help decrease any feelings of intimidation. Children have the ability to express themselves and take part in their healthcare, so if the child is present, include the child in the conversation. Several techniques are helpful when communicating with children. Play, the universal language, allows children to use other symbols, not just words, to express themselves. Drawing, painting, and other art forms can be used even by nonverbal children. Storytelling, in which the nurse and child take turns adding to a story or putting words to pictures, can help the child safely express emotions and feelings. Word games that pose hypothetical situations or put the child in control, such as "What if . . . ?" "If you could . . . ," or "If a genie came and gave you a wish . . ." can help a child feel more powerful or explore ideas about how to manage an illness. Reading books with a theme similar to the child's condition or problem and then discussing the meaning, characters, and feelings generated by the book can help the nurse communicate with the child about the condition and the child's experiences with it. Movies or videos can also be used in this way. Older children can use writing to reflect on their situation, develop meaning, and gain a sense of control.

Communicating with Adolescents

Adolescents have the ability to think abstractly and make decisions about their own healthcare. Adolescents are focused on the development of effective communication skills and feel a strong need to share thoughts, facts, and feelings with others (Koutoukidis, Stainton, & Hughson, 2013). It takes time to build rapport with adolescents. Nurses working with adolescents should use active listening and project a nonjudgmental attitude and nonreactive behaviors, even when an adolescent makes disturbing comments. Adolescents are very sensitive to feelings of judgment, so it is essential to remain open minded when communicating with them. Adolescents prefer expectations to be clearly explained, and they appreciate when praise is given.

Communicating with Adults

Young adults and middle-aged adults are at the peak of their communication abilities. They are fully grown/developed, and many have either completed their education or are earning advanced degrees. However, there is a wide range of communication abilities among adults based on cognitive ability, education levels, socioeconomic levels, exposure to professional and work environments, and health literacy. Young adults may still display some adolescent patterns of communication. And at the upper end of middle age, some adults may begin to have physical and cognitive problems usually seen in older adults. Nurses should identify any barriers to communication with adults and plan accordingly.

Communicating with Pregnant Women

Optimal pregnancy outcomes depend on clear communication, effective decision making, and teamwork (Zote, 2014). Effective therapeutic communication is essential to patient safety, creates a climate of confidence, and strongly affects the patient's comfort with the process of pregnancy and birth. Nurses can promote the patient's self-expression by establishing a therapeutic relationship, making the family

feel welcome, and being nonjudgmental. Keys to communication during pregnancy include determining the cultural values of the family about birth, engaging in shared decision making, and listening to the patient as well as providing support. Refer to the module on Reproduction for more information on communicating with pregnant women.

Communicating with Older Adults

Older adults may have physical or cognitive problems that necessitate nursing interventions to improve communication. Some of the common problems include sensory deficits; cognitive impairment; neurologic deficits from strokes or other neurologic conditions; and psychosocial problems, such as depression. Recognizing specific needs and obtaining appropriate resources for patients can greatly increase their socialization and quality of life. Nurses can use a number of different interventions to improve communication in patients with these special needs. For example, nurses can ensure that the patient is using assistive devices, glasses, and hearing aids, and that these are in good working order. Nurses can also use communications aids, such as paper and pencil, communication boards, tablets or computers, or pictures, when possible. Referral to appropriate services and resources, such as speech therapy, may provide further support for the older adult who experiences communication difficulties.

To communicate effectively with older adults, the nurse should keep environmental distractions to a minimum. The nurse should seek to speak in short, simple sentences, one subject at a time, and reinforce or repeat what is said when necessary. In communicating effectively with older adults, the nurse must avoid elderspeak and should always face the patient when speaking; coming up behind someone may be frightening. Include family and friends in conversation. When verbal expression and nonverbal expression are incongruent, believe the nonverbal: clarification of this and careful attention to the patient's feelings will help promote a feeling of caring and acceptance. Find out what has been important and what has meaning to the patient, and try to maintain these things as much as possible. Simple things such as bedtime rituals become more important, especially in a hospital or extended-care setting.

NURSING PROCESS

Communication is an integral part of the nursing process. The nurse uses communication skills in each phase of the nursing process. Communication skills take on greater importance when the nurse is caring for a patient with sensory, language, developmental, or cognitive deficits. Timing also has a bearing on communication and patient care. See the Evidence-Based Practice feature for information on how nurses view timing related to providing nursing care.

Assessment

Assessment strategies related to communication include evaluating the patient's communication style and appraising any language or communication barriers. Remember that cultural values and practices may influence when and how a patient speaks. Obviously, language varies according to age and development. For example, with children,

the nurse observes sounds, gestures, facial expressions, and vocabulary.

Throughout the process of collecting data, the nurse uses communication skills to increase nurse-patient rapport, put the patient at ease when discussing personal matters, and interpret the patient's nonverbal communication, and to assess for and overcome barriers to communication as outlined below. Exemplar 38.B discusses the role of therapeutic communication in creating a helping relationship with the patient.

Language Deficits

The nurse determines whether the patient speaks another language or has an impairment that affects his or her ability to communicate verbally. When assessing for the need for an interpreter, remember that some patients who use English as a second language may have language skills that are inadequate to meet their needs in a healthcare environment.

Sensory Deficits

The abilities to hear, see, feel, and smell are important adjuncts to communication. A hearing impairment can significantly alter the message a patient receives; vision impairment may affect a patient's ability to observe nonverbal behavior, such as a smile or a gesture; and inability to feel and smell can impair the patient's ability to report injuries or detect smoke from a fire. If a patient appears to have severe hearing impairments, the nurse should follow these steps:

- Look for a medical alert bracelet, necklace, or tag indicating hearing loss.
- Determine whether the patient wears a functioning hearing aid.
- Observe whether the patient is attempting to see your face to read lips.
- Observe whether the patient is attempting to use hands to communicate with sign language.
- Evaluate feedback to validate that effective communication is taking place.

See the feature on Communicating with Patients Who Have a Visual or Hearing Deficit in the module on Sensory Perception for more information.

Cognitive Impairments

Any disorder that impairs cognitive functioning (e.g., cerebrovascular disease, dementia, and brain tumors or injuries) may affect a patient's ability to use and understand language. These patients may develop total loss of speech, impaired articulation, or the inability to find or name words. They may experience difficulty understanding others or tracking conversations, which may manifest through withdrawal, frustration, or changing the subject. Certain medications such as sedatives, antidepressants, and neuroleptics may also impair speech, causing the patient to use incomplete sentences or to slur words. Older adults are particularly likely to have cognitive impairments that may interfere with communication.

The nurse assesses whether these patients respond when asked a question and, if they do, assesses the following:

- Is the patient's speech fluent or hesitant?
- Does the patient use words correctly?

- Can the patient comprehend instructions as evidenced by following directions?
- Can the patient repeat words or phrases?

In addition, the nurse assesses the patient's ability to understand written words:

- Can the patient follow written directions?
- Can the patient respond correctly by pointing to a written word?
- Can the patient read aloud?
- Can the patient recognize words or letters even if unable to read whole sentences?

The nurse uses large, clearly written words when trying to establish abilities in this area.

SAFETY ALERT When the patient is unconscious, the nurse looks for any indication that suggests the patient has some ability to comprehend and communicate (e.g., tries to arouse the patient verbally and through touch). Ask a closed question such as "Can you hear me?" and watch for a nonverbal response such as a nod of the head for yes or a shake for no, or ask for a hand squeeze or blink of the eye: once for yes or twice for no. Because damage to the spinal cord may preclude movement, attempts to determine comprehension must be specific to the needs of the individual patient.

Other Impairments

Structural deficits of the oral and nasal cavities and respiratory system can alter an individual's ability to speak clearly and spontaneously. Examples include cleft palate, artificial airways such as an endotracheal tube or tracheostomy, and laryngectomy (removal of the larynx). Extreme dyspnea (shortness of breath) can also impair speech patterns.

If verbal impairment is combined with paralysis of the upper extremities that impairs the patient's ability to write, the nurse should determine whether the patient is able to point, nod, shrug, blink, or squeeze a hand. Any of these could be used to devise a simple communication system.

Style of Communication

In assessing communication style, the nurse considers both verbal and nonverbal communication. In addition to physical barriers, some psychologic illnesses (e.g., depression or psychosis) influence the patient's ability to communicate. The patient may demonstrate constant verbalization of the same words or phrases, a loose association of ideas, a flight of ideas (a continuous flow of rapid speech that switches from topic to topic), or other indicators of barriers posed by psychologic processes.

Verbal Communication

When assessing verbal communication, the nurse focuses on three areas: the content of the patient's message, the themes, and the emotions the patient verbalizes. In addition, the nurse considers the following:

- Whether the patient's communication pattern is slow, rapid, quiet, spontaneous, hesitant, evasive, and so on
- The patient's vocabulary, particularly any changes from the vocabulary normally used (for example, someone

who normally never swears may indicate increased stress or illness by an uncharacteristic use of profanity)

- The presence of hostility, aggression, assertiveness, reticence, hesitance, anxiety, or loquaciousness (incessant verbalization) in communication
- Difficulties with verbal communication, such as slurring, stuttering, inability to pronounce a particular sound, lack of clarity in enunciation, inability to speak in sentences, loose association of ideas, flight of ideas, or the inability to find or name words or identify objects
- The refusal or inability to speak.

SAFETY ALERT Changes in the patient's ability to put words together into sentences or to properly name an item or struggling to find the right word for common objects may be an indication of neurologic impairment. Assessment of the patient's communication ability, especially after any type of head trauma, is an important tool for detecting alterations in the patient's condition.

Diagnosis

Impaired Verbal Communication may be used as a nursing diagnosis when an individual experiences "a decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols" (NANDA-I, 2014). Communication problems may be *receptive* (e.g., difficulty hearing) or *expressive* (e.g., difficulty speaking).

A nursing diagnosis of *Impaired Verbal Communication* may not be useful when an individual's communication problems are caused by a psychiatric illness or acute anxiety or emotional distress. In those instances, a diagnosis of *Fear* or *Anxiety* may be more appropriate. Impaired verbal communication has implications for the patient in a number of areas, including patient self-esteem and social isolation.

Planning

When a nursing diagnosis related to impaired verbal communication has been made, the nurse and patient determine outcomes and begin planning ways to promote effective communication. Establishing communication with the patient may require creativity or technology. New devices are being developed, ranging from thought-activated computers that verbalize for the patient to devices that can be operated with a stylus in the mouth to verbalize needs.

Specific goals for nursing interventions will depend on the stated etiology and may include the following:

- The patient will have an effective means for communicating needs.
- The patient's ability to perceive messages accurately will be maximized.
- The patient will be provided with resources as needed to optimize the ability to communicate.

Implementation

Nursing interventions to facilitate communication with patients who have problems with speech or language include manipulating the environment, providing support,

Evidence-Based Practice

The Role of Time in Caring for the Patient with Complex Communication Needs

Problem

Effective nurse–patient communication is an essential aspect of healthcare. As Kourkouta and Papathanasiou (2014) note, “Good communication between nurses and patients is essential for the successful outcome of individualized nursing care of each patient.” Unfortunately, time to communicate is often limited and subject to the workload demands of the nurse. Especially in the current era of healthcare institutions cutting costs and staff to stretch their limited resources, nurses are faced with more time pressure, a development that has been shown to undercut the quality of care for all patients (Ball et al., 2013). Little is currently known about how nurses manage the “lack of time” when caring for patients with developmental disabilities and those with complex communication needs. These groups tend to communicate at slower rates and a more concrete level, which can further undermine the communication process.

Evidence

Hemsley, Balandin, and Worrall (2012) investigated nurses’ expressed concepts of “time” in stories about communicating with patients with developmental disabilities. They interviewed 15 nurses from two large hospitals about barriers to and strategies for successful communication with patients who have developmental disabilities.

The nurses identified “time” as both a barrier and a facilitator to a successful communication process. Time was a barrier when related to avoiding direct communication. It was also used as a means to avoid direct communication with patients and instead communicate with family members or other paid caregivers on behalf of the patient. Nurses viewed time positively when related to valuing communication, investing extra time, and the application of a range of adaptive communication strategies that established successful communication.

Implications

Time is perceived as both an enemy and a friend for the improvement of communication. Nurses who perceive that communication takes too long may avoid the communication process and miss opportunities to improve it. Those who take the time to communicate apply a wide range of strategies in order to achieve successful communication with patients.

Critical Thinking Application

1. What resources can the nurse use to communicate with patients with complex communication needs in the hospital setting?
2. What resources might the nurse use to communicate with these patients once they are discharged into the community?

employing measures to enhance communication, and educating the patient and support person.

Manipulate the Environment

A quiet environment with limited distractions provides the best setting for communication and increases the possibility of effective communication. Sufficient light helps in conveying nonverbal messages, which is especially important if visual or auditory acuity is impaired. Initially, the nurse needs to provide a calm, relaxed environment, which will help reduce any anxiety the patient may have. Any factor that affects communication can create feelings of frustration, anxiety, depression, or hostility in a patient. Communication normally contributes to a patient’s sense of security and feelings of not being alone, so communication problems may cause some patients to feel isolated and confused. To reduce feelings of isolation, the nurse should acknowledge and praise the patient’s attempts at communication.

Provide Support

The nurse should convey encouragement to the patient and provide nonverbal reassurance, perhaps by touch if appropriate. If the nurse does not understand a patient’s communication, it is critical to let the patient know so that the patient can provide clarification with other words or through some other means of communication. When speaking with a patient who has difficulty understanding, check frequently to determine what the patient has heard and understood. Using open-ended questions will assist in obtaining accurate information about the effectiveness of communication.

Clinical Example B

You are providing care to Maria Perez, a 52-year-old Latina patient who has limited English skills. As part of the discharge teaching for this patient, you are teaching her about dietary changes that are necessary for managing Crohn disease. You ask Ms. Perez, “Do you understand what to eat?” She nods her head yes. You realize that the question did not elicit an answer that sufficiently confirms that Ms. Perez understood. You ask a follow-up question: “What do you think will be good for you to eat when you go home?” At the same time, your body language (e.g., gestures, posture, facial expression, and eye contact) conveys acceptance and approval. When Ms. Perez begins to explain what foods she should avoid, you are confident that you communicated the information to Ms. Perez successfully.

Critical Thinking Questions

1. What resources are available for teaching patients whose primary language is not English?
2. How does culture affect communication?
3. How does body language affect the communication process?

Employ Measures to Enhance Communication

To enhance communication, the nurse first determines how the patient can best receive messages: by listening, by looking, through touch, or through an interpreter. Ways to help communication include keeping words simple and concrete and discussing topics of interest to the patient. The use of alternative communication strategies, such as word boards, pictures, paper and pencil, or an iPad or other tablet may be helpful.

Avoid Potential Cultural Barriers to Communication

The nurse should remember several items when communicating with a patient whose primary language is not English. Avoid the use of slang, buzzwords, and medical terminology when possible. Show the patient respect by speaking clearly, directly, and at a normal pace. Avoid words that may impede the communication process, such as words that are slurred and those that have several syllables. Speak at a speed that does not overload the patient and allows the patient to follow the conversation. However, avoid speaking too slowly, because this may cause the nurse to lose the patient's attention. Use open-ended questions and rephrase them as necessary to obtain accurate information.

When using nonverbal communication with these patients, select gestures with care. This form of nonverbal communication underscores both words and actions and can be used to clarify meaning; however, gestures may have different meanings for different cultures. Therefore, the nurse must validate words and gestures with each patient on an individual basis.

If language is a barrier, the use of an interpreter may be necessary. In 2000, the federal Office for Civil Rights (OCR) of the Department of Health and Human Services mandated that any healthcare providers and agencies that receive federal funds must communicate effectively with patients, family members, and visitors who are deaf or hard-of-hearing and must take steps to provide meaningful access to their programs for persons who have limited English proficiency (LEP). Failure to do so is considered discrimination. OCR makes "information, resources, and tools available to healthcare organizations that assist people with limited English proficiency and people who are deaf or hard of hearing" (OCR, 2016).

Because the use of family members as interpreters can raise confidentiality and privacy issues, the nurse should enlist the aid of bilingual staff members to communicate information effectively. Most healthcare institutions have a list of bilingual staff members who can be used as personal interpreters, medical interpreters, or both. When working with an interpreter, the nurse must remember to always speak directly to the patient and not to the interpreter.

The nurse who is culturally competent will be appreciated by the patient. The following strategies can be used when caring for patients from a different culture:

1. Use the proper form of address for the patient's culture.
2. Know how individuals in the patient's culture greet one another. This may include the use of handshake, embraces, or kissing the cheeks. In some cultures, physical contact is prohibited.
3. Be aware of what a smile means in the patient's culture. A smile may indicate friendliness or be considered taboo. Also be aware of what eye contact means; in some cultures, it indicates respect, whereas in others, it may indicate aggression or be considered impolite.
4. Remember that not all gestures have a universal meaning.

While similarities may enhance the therapeutic relationship, differences can serve as topics for open discussion. Having an open and ongoing conversation between all parties will promote understanding.

Evaluation

Evaluation is useful for both patient and nurse communication. Evaluation of nurse communication is discussed in greater detail in Exemplar 38.B on therapeutic communication.

To establish whether patient outcomes have been met in relation to communication, listen actively and observe nonverbal cues. The overall patient outcome for individuals with impaired verbal communication is to reduce or resolve the factors impairing the communication. Examples of statements indicating outcome achievement include "Using a picture board effectively to indicate needs" or "The patient stated, 'I listened more closely to my daughter yesterday and found out how she feels about our divorce.'"

Examples of outcomes of care for the patient with impaired communication include the following:

- The patient communicates that needs are being met.
- The patient perceives the message accurately, as evidenced by appropriate verbal and/or nonverbal responses.
- The patient communicates effectively, using the patient's dominant language, a translator/interpreter, sign language, a word board or picture board, and/or a computer.
- The patient has regained maximum communication abilities.
- The patient expresses minimal fear, anxiety, frustration, and depression.
- The patient uses resources appropriately.

Nursing Practice

Communication is a critical skill for nursing. It is the process by which humans meet their survival needs, build relationships, and experience emotions. In nursing, communication is a dynamic process used to gather assessment data, to teach, to collaborate with other healthcare professionals, to advocate for patients, to express caring, and to provide comfort. It is an integral part of the helping relationship.

Four specific types of communication are explored in the exemplars of this module. Each of these is essential to successful nursing practice. Group communication is becoming ever more important in the process of making decisions in the current healthcare system. Therapeutic communication is an essential tool for developing the nurse-patient helping relationship. Documentation is the primary form of written communication used by nurses in all aspects of healthcare. Finally, reporting through handoff communication is the process of nurse-to-nurse communication that ensures continuity of care for the patient from one shift change or visit to another.

REVIEW The Concept of Communication

RELATE Link the Concepts

Linking the concept of communication with the concept of culture and diversity:

1. How can misunderstanding the patient's culture act as a barrier to communication when the nurse's culture differs from that of the patient?
2. The nurse is studying a culture different from the one in which the nurse was raised. What aspects of the culture would the nurse wish to learn about in order to understand how that culture's communication style may differ?

Linking the concept of communication with the concept of professional behaviors:

3. How do the nurse's communication skills affect the perceptions of others (both patients and other members of the healthcare team) regarding the nurse's professionalism?
4. A patient asks the nurse a question. Although the nurse is very knowledgeable about the subject, the nurse stumbles over words while answering the patient, repeatedly starts sentences over again, uses words such as "ahh" and "umm" a number of times, and gives the impression of weighing each word carefully. What impact will this delivery have on the patient's perception of the nurse's professionalism and knowledge of the subject matter being explained?

Linking the concept of communication with the concept of immunity:

5. How can a nurse's communication skills produce positive and negative patient teaching outcomes for patients with systemic lupus erythematosus?

6. Discuss some of the difficulties in communicating about a condition such as HIV/AIDS, which carries a social stigma. How can a nurse most effectively provide communication and allow the patient to express him- or herself?

REFLECT Apply Your Knowledge

Madeline McCormick, 24 years old, is an RN who has worked in the local acute care hospital on the medical floor for the past 3 years. Last night her boyfriend proposed. She accepted and is so thrilled she can't wait to show her new diamond ring to all of her coworkers and tell them the good news. She arrives at work early to share the good news and they all congratulate her and shower her with questions about her ideas for the wedding.

You are a student nurse assigned to Ms. McCormick's floor today. As you walk by one of the patients' rooms you hear Ms. McCormick, who is providing a.m. care to a patient, talking to the patient and telling her all about how her boyfriend proposed, her wedding plans, and how happy she is.

1. Is it appropriate for Ms. McCormick to share her good news with her coworkers? Why or why not?
2. Is it appropriate for Ms. McCormick to share her news with her patient? Why or why not?
3. How does Ms. McCormick's excitement over her engagement affect the nurse-patient communication process?

Exemplar 38.A

Groups and Group Communication

Exemplar Learning Outcomes

38.A Analyze groups and group communication.

- Describe the types, functions, levels of formality, and characteristics of effective groups.
- Outline the aspects of group dynamics.
- List group problems that nurses should recognize and avoid.
- Describe types and functions of healthcare groups.

Overview

A **group** is defined by Adams and Galanes (2014) as "three or more individuals who have a common purpose, interact with each other, influence each other, and are interdependent" (p. 11). Nurses participate in groups on a regular basis and may function as either a leader or a participant depending on

the nature of the group and the nurse's qualifications. Group processes, called *group dynamics*, determine how groups function. For group work to be accomplished and goals to be achieved, group dynamics must be effective.

The changing healthcare system presents challenges for healthcare professionals if they are to be actively involved in decisions about policy and practice. Such decisions are made

by groups of individuals at all levels of society: think tanks, advocacy groups, professional groups, and politicians at local, regional, state, national, and international levels. These challenges provide opportunities for nurses to participate as active members of the various decision-making groups. To be effective members of these groups, nurses must be knowledgeable about the dynamics of group interaction.

Groups

Groups exist to help individuals achieve goals that might be unattainable through individual effort alone. By pooling the ideas and expertise of several individuals, groups often can solve problems more effectively than one person acting alone (see the Concept of Collaboration). Information can be disseminated to groups more quickly and with more consistency than to individuals. In addition, groups often take greater risks than do individuals because group members support each other in decision making. Just as group members share responsibilities for the group's actions, they also share the consequences of those actions.

In the clinical setting, nurses work in groups as they collaborate with other nurses, other healthcare professionals, patients, and family members when planning and providing care. Nurses also work in groups in professional and specialty organizations and civic and community groups. Within these organizations, nurses promote the goals of nursing on professional, civic, and political levels. Group skills are therefore important for nurses in all settings.

Types of Groups

Groups are classified as either primary or secondary, according to their structure and type of interaction. A **primary group** is a small, intimate group in which the relationships among members are personal, spontaneous, sentimental, cooperative, and inclusive. Examples are the family, a play group of children, informal work groups, and friendship groups. Members of a primary group communicate with each other largely in face-to-face interactions and develop a strong sense of unity, or "oneness." What belongs to one person is often seen as belonging to the group. For example, a success achieved by one member is shared by all and is seen as a success of the group.

Primary groups set standards of behavior for their members. They also support and sustain each member in stressful situations that the member would otherwise not be able to withstand. In particular, the role of the primary group, particularly the family, in healthcare is increasingly recognized. Most individuals turn to their primary group for help and support when they have health problems. For this reason, healthcare providers and organizations expand their focus to include the family.

A **secondary group** is generally larger, more impersonal, and less sentimental than a primary group. Examples are professional associations, task groups, ad hoc committees, political parties, and business groups. Members view these groups simply as a means of getting things done. Interactions do not necessarily occur in face-to-face contact and do not require that the members know each other personally. Expectations of members are formally administered through impersonal controls and external restraints. Once the goals of the group are achieved or change, the interaction is discontinued.

Functions of Groups

Two classic studies outline the functioning of groups. Sampson and Marthas (1990) describe eight functions of groups: socialization, support, task completion, camaraderie, information, normative function, empowerment, and governance. Stewart, Manz, and Sims (1999) describe two ways of categorizing groups: functional perspectives and interpersonal perspectives. Any one group generally can have more than one function, and it may fulfill different functions for different group members. For example, for one member, a group may provide support; for another, it may provide information.

Levels of Group Formality

The three levels of groups are **formal**, **semiformal**, and **informal**. Traditional features of each type of group are shown in **Box 38-2** ».

Characteristics of Effective Groups

To be effective, a group must achieve three main functions:

1. Accomplish its goals.
2. Maintain its cohesion.
3. Develop and modify its structure to improve its effectiveness.

Many factors can promote or inhibit a group's ability to achieve these functions. These include atmosphere, ability to set goals, and intergroup communication (**Figure 38-7** »). These and other factors are compared in **Table 38-3** ».

Group Communications

Group Dynamics

Group dynamics, which are also known as group processes, are related to how the group functions, communicates, sets goals, and achieves objectives. Every group has its own characteristics and ways of functioning. Five aspects of group dynamics are commitment, decision-making ability, member behavior, cohesiveness, and power.

Box 38–2

Characteristics of Formal, Semiformal, and Informal Groups

Formal Groups	Semiformal Groups	Informal Groups
<ul style="list-style-type: none"> ■ Authority is imposed from above. ■ Leadership selection is assigned from above and made by an authoritative and often arbitrary order or decree. ■ Managers are symbols of power and authority. ■ The goals of the formal group are normally imposed at a much higher level than the direct leadership of the group. ■ Management is endangered by its aloofness from the members of the work group. ■ Behavioral norms (expected standards of behavior), regulations, and rules are usually superimposed. The larger the turnover rate of members, the greater the structuring of rules. ■ Membership in the group is only partly voluntary. ■ Rigidity of purpose is often a necessity for protection of the formal group in the pursuit of its objectives. ■ Interactions within the group as a whole are limited, but informal subgroups often are formed. 	<ul style="list-style-type: none"> ■ The structure is formal. ■ The hierarchy is carefully delineated. ■ Membership is voluntary but selective. ■ Prestige and status are often accrued from membership. ■ Structured, deliberate activities absorb a large part of the group's meeting time. ■ Objectives and goals are rigid; change is not recognized as desirable. ■ In many cases, the leader has direct control over the choice of a successor. ■ The day-to-day operating standards and methods (group norms) are negotiable. Because most people become bored at quibbling about norms, someone can often "railroad" acceptance of a list of norms that person desires. 	<ul style="list-style-type: none"> ■ The group is not bound by any set of written rules or regulations. ■ Usually governed by a set of unwritten laws and a strong code of ethics. ■ The group is purely functional and has easily recognized basic objectives. ■ Rotational leadership is common. The group recognizes that only rarely are all leadership characteristics found in one person. ■ The group assigns duties to the members best qualified for certain functions. For example, the person who is recognized as outgoing and sociable will be assigned responsibilities for planning parties. ■ Judgments about the group's leader are made quickly and surely. Leaders are replaced when they make one or more mistakes or do not get the job done. ■ The group is an ideal testing ground for new leadership techniques, but there is no guarantee that such techniques can be transferred effectively to a large, formal organization. ■ Behavioral norms are developed either by group effort or by the leader and adopted by the group. ■ Deviance by one member from the group's behavioral norms is more threatening to the perpetuation of small, informal groups than to large, formal, heterogeneous groups. Conformity and group solidarity are important for the protection and preservation of small groups. ■ Group norms are enforced by sanctions (punishments) imposed by the group on those who violate a norm. Different values are placed on norms in accordance with the values of the leader. One leader may regard the action as a gross violation, whereas another leader may find it quite acceptable. ■ Interpersonal interactions are spontaneous.

Commitment

The members of effective groups are committed to the goals and output of the group. Because groups demand time and attention, members must give up some autonomy and self-interest. Inevitably, conflicts arise between the interests of individual group members and those of the group as a whole. However, members who are committed to the group feel close to each other and willingly work for the achievement of the group's goals and objectives. Indications of group commitment include:

- Members feel a strong sense of belonging.
- Members enjoy each other.
- Members seek each other for counsel and support.
- Members support each other in difficulty.
- Members value the contributions of other members.
- Members are motivated by working in the group and want to do their tasks well.

- Members express good feelings openly and identify positive contributions.
- Members feel that the goals of the group are achievable and important.

Decision-making Methods

The ability to make sound decisions is essential to effective group functioning. Effective decisions are made when the following occur: when the group listens to all the ideas of its members and members feel satisfied with their participation; when the group atmosphere is positive; when the group uses time efficiently by focusing the discussion on the decision to be made; and when members feel committed to the decision and responsible for its implementation.

Huber (2014) describes several methods by which groups can make decisions: trial and error, pilot projects, creativity techniques, decision trees, scenario planning, and worst-case scenario. **Trial and error** techniques are the most haphazard: in these situations, a solution that seems viable is

TABLE 38–3 Comparative Features of Effective and Ineffective Groups

Factor	Effective Groups	Ineffective Groups
Atmosphere	Informal, comfortable, and relaxed. It is a working atmosphere in which individuals demonstrate their interest and involvement.	Obviously tense. Signs of boredom may appear.
Goal setting	Goals, tasks, and objectives are clarified, understood, and modified so that members of the group can commit themselves to cooperatively structured goals.	Unclear, misunderstood, or imposed goals may be accepted by members. The goals are competitively structured.
Leadership and member participation	Shift from time to time, depending on the circumstances. Different members assume leadership at various times, because of their knowledge or experience.	Delegated and based on authority. The chairperson may dominate the group, or the members may defer unduly. Members' participation is unequal, with high-authority members dominating.
Goal emphasis	All three functions of groups are emphasized: goal accomplishment, internal maintenance, and developmental change.	One or more functions may not be emphasized.
Communication	Open and two-way. Ideas and feelings are encouraged, both about the problem and about the group's operation.	Closed or one-way. Only the production of ideas is encouraged. Feelings are ignored or taboo. Members may be tentative or reluctant to be open and may have "hidden agendas" (personal goals at cross purposes with group goals).
Decision making	By consensus, although various decision-making procedures appropriate to the situation may be instituted.	By the higher authority in the group, with minimal involvement by members or an inflexible style is imposed.
Cohesion	Facilitated through high levels of inclusion, trust, liking, and support.	Either ignored or used as a means of controlling members, thus promoting rigid conformity.
Conflict tolerance	High. The reasons for disagreements or conflicts are carefully examined, and the group seeks to resolve them. The group accepts unresolvable basic disagreements.	Low. Attempts may be made to ignore, deny, avoid, suppress, or override controversy by premature group action. The group may choose to live with conflict rather than attempt to resolve it.
Power	Determined by the members' abilities and the information they possess. Power is shared. The issue is how to get the job done.	Determined by position in the group. Obedience to authority is strong. The issue is who controls.
Problem solving	High. Constructive criticism is frequent, frank, relatively comfortable, and oriented toward removing an obstacle to problem solving.	Low. Criticism may be destructive, taking the form of either overt or covert personal attacks. It prevents the group from getting the job done.
Self-evaluation of the group	Frequent. All members participate in evaluation and decisions about how to improve the group's functioning.	Minimal. What little evaluation there is may be done by the highest authority in the group rather than by the membership as a whole.
Creativity	Encouraged. There is room within the group for members to become self-actualized and interpersonally effective.	Discouraged. People are afraid of appearing foolish if they put forth a creative thought.

simply attempted. Managers and groups who use these techniques typically are seen as poor problem solvers, especially in a healthcare context. Evidence-based practice protocols have replaced trial and error as the standard in the nursing profession.

Pilot projects make use of limited trials to determine problems with problem-solving alternatives. Pilot project strategies may resemble research projects and may be linked to quality improvement initiatives. **Creativity techniques** such as brainstorming sessions use the creative potential of the group to generate a large number of possible options quickly. A **decision tree** is a graphic model that visually represents the choices, outcomes, and risks to be anticipated. A decision tree helps groups visualize the results of a series of branching options and helps streamline decision making by clearly spelling out alternative options as decisions lead to subsequent options.

Scenario planning is a group process strategy that encourages members of a group to create hypothetical or "possible future" situation. Scenario planning is most applicable to fluid and changing environments. Participants are encouraged to ask themselves, "What if?" Group members imagine pathways, forces in play, turning points, and deep behavioral undercurrents. Scenario planning helps illuminate early warning signs, create opportunities, and ensure against risks.

Worst-case scenario is a technique designed to help groups make decisions that involve risk. The worst-case outcome is outlined for each alternative, and then the scenario with the comparatively best outcome is selected as the preferred outcome. This technique helps ensure that the "least of all evils" is selected.

Member Behavior

The degree of input by members into goal setting, decision making, problem solving, and group evaluation is related to the group structure and leadership style, but members are responsible for their own behavior and participation. Each member participates in a wide range of roles (assigned or assumed functions) during group interactions. Individuals may perform different roles during interactions in the same group or may vary roles in different groups. Various roles have been identified. These include *information givers*, who provide factual information; *information seekers*, who seek factual information about tasks at hand; and *opinion givers*, who care more about values and beliefs than facts.

Cohesiveness

Groups that have cohesiveness possess certain characteristics. One characteristic is a group spirit. This is a sense of having a common purpose. **Cohesiveness** is the attachment

that members feel toward each other, the group, or the task. Members of groups that have a high level of cohesiveness feel greater satisfaction with the group. Groups that lack cohesiveness are unstable and are more prone to disintegration.

SAFETY ALERT Effective group communication is essential for the patient's safety because the patient's care is overseen by an interdependent healthcare team. Team members must coordinate their efforts to ensure that medications are given in the correct dose at the correct time, that necessary education is provided, and that all interventions are implemented correctly. Poor group atmosphere, goal setting, leadership, goal emphasis, and all the other elements of group cohesion have a direct and cumulative impact on patient outcomes and safety.

Power

Patterns of behavior in groups are greatly influenced by the force of power. Power can be defined as the ability to influence another person in some way or the ability to do something, whether it is to decide the fate of a nation or to decide that a certain change in policy or practice is necessary. For example, a new member of a group may be more influenced by the group member who asked her to enter into membership than by other members. Similarly, group members may afford power to those group members who most closely share their interests.

Many individuals have a negative concept of power, likening it to control, domination, and even coercion of others by muscle and clout. However, power can be viewed as a vital, positive force that moves people toward the attainment of individual or group goals. The overall purpose of power is to encourage cooperation and collaboration in accomplishing a task.

Group Problems

In addition to conflict, problems that can occur in groups include monopolizing, groupthink, scapegoating, silence and apathy, and transference and countertransference. The nurse needs to be able to recognize and avoid these behaviors when working in collaborative groups because these behaviors function as barriers to successful group work.

Monopolizing

Monopolizing is the domination of a discussion by one member of a group. Because most group meetings have time restraints, monopolizing seriously deprives other individuals of their chance to participate. A sense of resentment among members then develops, and ultimately some members may direct their frustration and anger toward the group leader, whom they expect to do something to stop the monopolizer's behavior.

Monopolizing behavior may be motivated by anxiety or a need for attention, recognition, and approval. Often, compulsive talkers are unaware of their behavior and its effect on others and need help to recognize their behavior and its consequences.

Strategies for dealing with monopolizing include the following:

- **Interrupt simply, directly, and supportively.** This strategy is an initial attempt to get the individual to hear others.

- **Reflect the member's behavior.** This strategy is an attempt to help the individual become aware of the monopolizing behavior.
- **Reflect the group's feelings.** This strategy is an attempt to help the individual member become aware of the effects of his behavior on others.
- **Confront the person and/or the group.** This strategy can be directed toward the individual or toward the group to help members realize their own responsibility for the problem.

Groupthink

Groupthink is a type of decision making characterized by a group's failure to critically examine its own processes and practices. Groupthink may also occur when members of a group fail to recognize and respond to change. It may occur in highly cohesive groups when group members do not want to disagree or criticize the majority of the group's thinking for fear of being considered disloyal. For example, the administrators of a local urgent care center, failing to recognize that the staff is struggling to communicate with their many Latino patients, refuse to hire Spanish-speaking staff or engage the services of a full-time interpreter. Symptoms of groupthink include the group overestimating its power and morality, the group becoming closed minded, and group members experiencing pressure to conform.

Scapegoating

A **scapegoat** is an individual who has been selected to take the blame for another individual or for a group. Individuals and groups who engage in scapegoating minimize their own feelings of ineptitude by focusing on the weakness of others. For leaders to deal with scapegoating, they must be alert to its development and be prepared to accept anger when they confront individuals who are scapegoating. Scapegoating is a grossly unprofessional behavior that has no place within the profession of nursing, which emphasizes responsibility and accountability.

Silence and Apathy

Nonparticipation or **apathy** (lack of interest or enthusiasm) of one or more group members is sometimes best handled without intervention. Sometimes such silences are not a reflection of something in the immediate group setting but rather of some past experience. For example, after expressing an idea previously, this person may have been told "That was a stupid thing to say." Having been hurt once in a group, such individuals feel insecure about their views and are reluctant to express themselves again in groups. Continued nonparticipation or apathy, however, needs to be dealt with by the leader after a careful assessment of whether the apathy is a reflection of leadership style, task issues, or interpersonal conflicts.

Transference and Countertransference

Transference in the group setting is defined as the transfer of feelings that were originally evoked by one's parents or significant others to individuals in the present setting. An example is a group member who acts toward the leader as

Focus on Diversity and Culture

Cross-cultural Group Communication

Group communication is difficult under any circumstances, but it can be especially hard when members of the group have different cultural standards. Reeves (2016) provides some ideas for managing cross-cultural concerns in group communication. When communicating with members of the group who speak a different language or dialect, nurses should slow their rate of speech, attempt to communicate clearly and concisely, and keep statements simple. When group members come from different cultures, nurses should maintain respect and courtesy and avoid slang. Nurses should avoid humor, as humor does not necessarily translate across cultures, and nurses should adopt a formal communication approach until a group rapport is established. Nurses should ask for feedback to determine whether or not they are being understood and adjust accordingly. No matter the patient's culture, the nurse should honor the differences in cultures by using neutral tones, categorizations, and behaviors that are respectful of the patient's culture, and avoiding those which could be interpreted as offensive (Arnold & Boggs, 2013).

the member would act toward a parent. In addition, members of a group can transfer to others in the group personal feelings of love, guilt, or hate.

When leaders respond to group members because of reactions from earlier relationships, they are engaging in *countertransference*. For example, if a group member reminds a leader of a teacher who was menacing and demanding, the leader is likely to react with anxiety and may become unreasonably fearful. It is therefore important that group members and leaders recognize the possibility of overreaction because of countertransference and that it is not an unusual reaction among nurses who are highly involved in helping others.

Healthcare Groups

Much of a nurse's professional life is spent in a wide variety of groups. As a participant in a group, the nurse may be required to fulfill different roles as member or leader, teacher or learner, adviser or advisee. Common types of healthcare groups include committees or teams, task forces, teaching groups, self-help groups, therapy groups, and work-related social support groups. These various types of groups exhibit similarities and differences, as do the roles of nurses participating in them.

Committees or Teams

Committees are those groups that are relatively stable or those that are brought together in a formal manner. These are the most common type of work-related group. They usually have a specific purpose that is part of their organizational structure, and they typically meet at defined intervals. Examples are policy committees, quality improvement committees, healthcare planning committees, nursing organization committees, and governmental affairs committees. Committees may also be referred to as teams, such as nursing care teams or wound care teams. Teams are groups with

a small number of consistent individuals who are committed to a relevant shared purpose. Groups have performance goals, complementary and overlapping skills, and a common approach to their work.

The leader of a committee or team must be accepted by the members as an appropriate leader and, therefore, should be an expert in the area of the committee's focus. The leader's role is to identify the specific task, clarify communication, and assist in expressing opinions and offering solutions. Within a single organization, committee or team members are generally selected on the basis of their individual functional roles and employment status rather than their personal characteristics. If a committee or team is composed of representatives from multiple organizations, the members are generally assigned by the member organizations. Committee members may reflect diverse expertise in order to assist the committee in achieving its purpose. In some cases, membership might be designated by rule or law. For example, membership in county child fatality review teams typically is designated by law and includes representatives of local hospitals, emergency medical systems, law enforcement, community health nurses, and so forth. Additional member positions, often called "at-large" positions, may be designated to enable local committees to add members from organizations whose membership would be helpful but who are not on the list of those designated by rule or law. Regardless of the type of committee or team, members are accountable for the group's results or outcomes.

Task Forces

Task forces or ad hoc committees are work groups that usually have a defined task that is limited in duration. In other words, the task force is brought together to perform a specific activity, such as preparation for a visit by The Joint Commission or Nurse Week. When the activity has been accomplished, the task force is dissolved. Task forces and ad hoc committees function in the same way as committees or work teams. The difference is in the duration of their work.

Teaching Groups

The major purpose of a teaching group is to impart information to the participants. Examples of teaching groups include group continuing education and patient healthcare groups. Numerous subjects are often handled using a group teaching format: childbirth techniques, exercise for older adults, and instructions to family members about follow-up care for discharged patients. A nurse who leads a group in which the primary purpose is to teach or learn must be skilled in the teaching-learning process discussed in the module on Teaching and Learning.

Self-Help Groups

A **self-help group** is a group of individuals who come together to face a common problem or difficulty. These groups are based on the helper-therapy principle: Those who help are helped most. A central belief of the self-help movement is that individuals who experience a particular social or health problem have an understanding of the condition that those without it do not. Twelve-step groups such

as Alcoholics Anonymous (AA) are self-help groups. Other support groups may consist of individuals who have specialized knowledge to help individuals who have the problem or who have experienced it.

Therapy Groups

Therapy groups are composed of individuals coming together to receive psychotherapy through which they work toward self-understanding, more satisfactory ways of relating or handling stress, and changing patterns of behavior around health. Members are referred to as patients, participants, or, in some settings, clients. They are selected by health professionals based on the pattern of personalities, behaviors, needs, and identification of group therapy as the treatment of choice. The number of sessions or the termination date is usually mutually determined by the therapist and members. Therapy groups are characterized by different

approaches to psychotherapy—for example, interpersonal groups, existential groups, cognitive-behavioral groups, and psychodrama.

Work-related Social Support Groups

Many nurses, especially hospice, emergency, and critical care nurses, experience high levels of vocational stress. Social support groups can help reduce stress if they provide various types of support to buffer the stress. Group members who know about the work of others can encourage and challenge members to be more creative and enthusiastic about their work. For example, a nurse may help another group member consider alternative strategies for intervention. Members also can share the joys of success and the frustration of failure through active listening without giving advice or making judgments. This type of social support is best provided outside the work-related support group.

REVIEW Groups and Group Communication

RELATE Link the Concepts and Exemplars

Linking the exemplar of groups and group communication with the concept of addiction:

1. How do individuals work in groups and use group communication when dealing with addiction?
2. What are some group communication types that may be useful when working with addicts in a group setting?

Linking the exemplar of groups and group communication with the concept of family:

3. How can families use group communication techniques to increase communication?
4. How might communication within a family be affected as a result of health alterations?

- Additional review materials

REFLECT Apply Your Knowledge

As a substance abuse nurse, you are responsible for leading daily meetings for a group of people who have addiction challenges. You have been asked to lead your first meeting now that you have finished your 6-week preceptorship and are now taking your own patient assignments on the unit. You are nervous about running a group independently. You begin to plan your session and want your mentor's input on whether you are planning a session that will be effective for the participants.

1. What type of meeting should you plan for this group?
2. What type of group problems might occur during the session?
3. After the session you feel that the group is ineffective. What characteristics would lead you to believe that this group is ineffective?

Exemplar 38.B Therapeutic Communication

Exemplar Learning Outcomes

38.B Analyze the interactive process of therapeutic communication.

- Summarize the various techniques used by nurses to support patients.
- Outline the phases of the therapeutic relationship.
- Explain ways that nurses can develop therapeutic relationships with patients.

Overview

Therapeutic communication is an interactive process between the nurse and the patient. It is an integral part of the **therapeutic relationship**, which is the caring relationship

- Differentiate considerations related to therapeutic communication throughout the lifespan.

Exemplar Key Terms

Physical attending, 2585

Therapeutic communication, 2583

Therapeutic relationship, 2583

between a nurse and a patient that is based on mutual trust and respect, sensitivity, and nurturing. Therapeutic communication helps the patient overcome temporary stress, get along with other people, adjust to situations that cannot be changed, and overcome any psychological blocks that may

stand in the way of self-realizations. Therapeutic communication promotes understanding and can help establish a constructive relationship between the nurse and the patient. Unlike the social relationship, which might not have a specific purpose or direction, the nurse establishes a therapeutic relationship with the purpose of helping the patient achieve health goals.

In therapeutic communication, the nurse responds not only to the content (words and thoughts) of a patient's verbal message but also to feelings the patient expresses and to nonverbal cues. It is important for the nurse to understand how the patient perceives a situation and feels about it before responding. Sometimes an individual can convey a thought in words that contradict the individual's emotions; that is, the patient's words and feelings are incongruent. For example, a patient might say, "I am glad he has left me; he was very cruel." However, the nurse observes that the patient has tears in her eyes as she says this. To respond to the patient's *words*, the nurse might simply rephrase, saying, "You are pleased that he has left you." To respond to the patient's *feelings*, the nurse would need to acknowledge the tears in the patient's eyes, saying, for example, "You seem saddened by all this." Such a response helps the patient focus on her feelings. In some instances, the nurse may need to know more about the patient and her resources for coping with these feelings.

Sometimes patients need time to deal with their feelings, especially before coping with certain activities such as learning new skills or planning for the future. This is most evident in hospitals when patients learn that they have a terminal illness. Some patients require hours, days, or even weeks before they are ready to start other tasks. Some need time to themselves, others need someone to listen, others need assistance identifying and verbalizing feelings, and others need assistance in identifying alternatives for future courses of action. However, while the nurse should help the patient explore alternatives, the nurse should not participate in the patient's decision making.

Therapeutic Communication Techniques

Therapeutic communication is intended to help patients reach an understanding about their condition or treatment while encouraging them to express feelings and ideas. Therapeutic communication is rooted in acceptance of the patient's point of view. Nontherapeutic communication, on the other hand, interferes with the nurse-patient relationship by putting barriers in the way of open communication (Evesham, 2016).

Therapeutic communication relies on active listening and continuous confirmation that both the nurse and the patient are being understood. In therapeutic communication, nurses take time to answer questions and encourage patients to satisfy their curiosity. In therapeutic communication, the nurse focuses on the most important issues and summarizes important points of communication to ensure that the patient understands the nurse and that the nurse understands the patient. Nontherapeutic communication detracts from patient care and includes behaviors such as asking irrelevant personal questions, sharing unnecessary

personal information of your own, or showing disapproval. False reassurance and sympathy are also aspects of nontherapeutic communication.

The nurse can employ a number of different communication techniques to support patients as they deal with their feelings related to their health and healthcare. The nurse must embrace these techniques and adapt them to each situation to improve communication with patients. However, no one technique will guarantee a successful encounter with all patients. Each situation is unique. The nurse should use a holistic approach to communicating with patients in each situation that is presented.

Empathizing

Active listening (described in depth later in the exemplar) is a skill that nursing students are taught throughout their education. Merely listening, however, is not enough. The nurse must have an empathetic understanding of the situation and offer appropriate feedback to the patient. *Empathy* is best described as a process in which individuals are able to put themselves in someone else's situation. By using empathy, the nurse is able to embrace the attitudes of each patient in each encounter.

To be able to empathize with patients, the nurse must be able to understand and acknowledge the ideas that the patient is expressing or that the patient feels are important to the situation. The nurse must also accept and respect the patient's feelings as valid for the patient, whatever those feelings may be, even if the nurse would not feel the same way in similar circumstances. Using empathy allows the nurse to connect with patients, and it also validates the importance of the patient's message to the nurse.

The term *empathy* is often mistakenly used to mean *sympathy*. Empathy, however, contains no elements of condolence, agreement, or pity. Empathy focuses on the patient's feelings, not the nurse's feelings. Nurses who sympathize rather than empathize assume that there is a parallel between their own feelings and the patient's feelings. This perceived similarity can make professional judgment and objectivity difficult. The nurse who empathizes can interpret the patient's feelings and does not insert his own feelings into the patient's current situation. The process of establishing empathetic understanding has four phases:

1. **Identification.** This phase involves the relaxation of conscious control. In this phase, the nurse is able to contemplate the patient and the patient's experiences.
2. **Incorporation.** In this phase, the nurse considers the patient's experiences and feelings rather than his own experiences.
3. **Reverberation.** This phase involves an interplay of the patient's internalized feeling with the nurse's own experiences or fantasies. The nurse is fully absorbed in the patient's identity but is able to experience himself separately.
4. **Detachment.** In this phase, the nurse withdraws from subjective involvement with the patient and resumes his own identity. The nurse uses the insight that was gained from the reverberation phase, along with reason and objectivity, to offer meaningful and useful responses to the patient.

Empathizing with patients who are troubled can have some stressful consequences for nurses. Problems can arise at any phase of the process, and when a nurse fails to cope with one of the four phases of achieving empathy, obstacles occur in terms of the nurse–patient relationship. The nurse should not identify too closely with the patient, because this can lead to sympathy rather than empathy.

Active Listening

Active listening, also called *attentive* or *mindful listening*, involves listening with multiple senses, in contrast to listening passively with just the ear. It is probably the most important technique in therapeutic communication and is the basis of all other techniques. Active listening requires energy and concentration. It is more than being quiet while the other individual talks—it involves paying attention to the total message, both verbal and nonverbal, and noting whether these communications are congruent. Active listening means absorbing both the content and the feeling the individual is conveying, without selectivity. The nurse does not select or listen solely to what she wants to hear; also, the nurse focuses not on her own needs but on the patient's needs. Active listening conveys an attitude of caring and interest, thereby encouraging the patient to talk (Figure 38–8 >>>).

Active listening also involves listening for key themes in the communication. The nurse must be careful not to react quickly to the message. The speaker should not be interrupted, and the nurse should take time to think about the message before responding. As a listener, the nurse also should ask questions either to obtain additional information or clarification and to ensure that the nurse fully understands the message.

Nurses need to be aware of their own biases. A message that reflects values or beliefs that differ from the nurse's should not be discredited for that reason. The patient, who is the sender, should decide when to close the conversation, and the nurse should listen for the signal that the patient is ready to do so. When the nurse closes the conversation, the patient may assume that the nurse considers the message unimportant.

Figure 38–8 >>> The nurse conveys active listening through a posture of involvement.

Box 38–3

Blocks to Active Listening

- **Rehearsing:** When the nurse is busy planning what to say next in the conversation
- **Being concerned with oneself:** When the nurse focuses on the nurse's own intelligence, competence, feelings, or accomplishments instead of focusing on the patient
- **Assuming:** When the nurse makes assumptions about what the patient is really trying to convey in the conversation
- **Judging:** When the nurse frames messages in the context of the nurse's own judgment about whether what the patient is saying is right or wrong, mature or immature, calm or anxious, sensible or paranoid, or depressed or simply quiet
- **Identifying:** When the nurse focuses on the nurse's own experiences, beliefs, or feelings; this may occur when what the patient communicates triggers memories or concerns from the nurse's own personal experiences
- **Getting off track:** When the nurse changes the subject or makes light of what the patient is expressing because the nurse is uncomfortable, bored, or tired
- **Filtering:** When the nurse tunes out certain topics in the conversation or hears only certain items that the patient is saying; this may occur because of anxiety on the part of the nurse.

There are some specific blocks to listening that may prevent the nurse from actually hearing what the patient says. This may convey a message to patients that what they have to say is not important (Box 38–3 >>>).

In summary, active listening is a highly developed skill that can be learned with practice. A nurse can listen actively and attentively to patients in various ways. Common responses that indicate active listening include nodding the head, uttering “uh huh” or “mmm,” repeating the words that the patient has used, or saying “I see what you mean.” Each nurse has characteristic ways of responding, and the nurse must take care not to sound insincere or patronizing.

Physical Attending

Physical attending is defined as the manner of being present to another or being with another. Listening, in a frame of reference, is what an individual does while attending. Five specific ways to convey physical attending, which in turn conveys involvement, include the following:

- **Look at the other person when speaking.** This position says, “I am available to you.”
- **Adopt an open posture.** The nondefensive position is one in which neither arms nor legs are crossed. It conveys that the individual wishes to encourage the passage of communication, as the open door of a home or an office does.
- **Lean toward the person.** Individuals move naturally toward one another when they want to say or hear something—by moving to the front of a class, by moving a chair nearer a friend, or by leaning across a table with arms propped in front. The nurse conveys involvement by leaning forward, closer to the patient.
- **Maintain good eye contact.** Mutual eye contact, preferably at the same level, recognizes the other individual and

denotes willingness to maintain communication. Eye contact neither glares at nor stares down another but is natural.

- **Try to be relatively relaxed.** Total relaxation is not feasible when the nurse is listening with intensity, but the nurse can show relaxation by taking time when responding, allowing pauses as needed, balancing periods of tension with relaxation, and using gestures that are natural.

These five attending postures need to be adapted to the specific needs and cultural practices of patients in a given situation. For example, leaning forward may not be appropriate at the beginning of an interview. It may be reserved until a closer relationship grows between the nurse and the patient. The same applies to eye contact, which is generally uninterrupted when the communicators are very involved in the interaction, but which may be uncomfortable for or viewed as inappropriate by some patients.

Therapeutic communication techniques facilitate communication and focus on the patient’s concerns. **Table 38–4** lists some common therapeutic communication techniques, with descriptions of the techniques and examples of their use. Touch can also be used as a part of therapeutic communication, but nurses are advised to use it with caution and intention (Anderson et al., 2016). As stated earlier, people from different cultures may view the use of touch differently. In addition, patients with a history of physical or sexual abuse and trauma and patients with certain mental illnesses, such as some personality disorders, may misinterpret the use of touch (Potter & Moller, 2016).

Using Silence

Nurses often feel that they must respond to each statement that is made by a patient. This, however, is not necessary.

The use of *silence* can be therapeutic and goes beyond active listening. The nurse who uses silence may sit or walk quietly with the patient. The goal is to provide a therapeutic purpose, such as:

- Encouraging the patient to communicate with the nurse
- Allowing the patient time to think about what has been said or to make connections
- Allowing the patient the necessary time to collect personal thoughts
- Allowing the patient time to consider possible alternatives.

The nurse who uses silence while remaining interested in what the patient is communicating maintains an open posture or a questioning look, which will encourage the patient to use the time effectively.

Silence is an effective communication technique only when it is used appropriately and purposefully for therapeutic communication. When an uncomfortable silence occurs, the nurse should break the silence and then analyze it. It is important not to allow the patient to become anxious or resistive. The nurse who is silent out of discomfort or a lack of knowledge or skill on how to communicate effectively should seek guidance from someone more experienced in order to analyze the personal and professional areas that are in need of growth.

Reflecting

In a 2013 article, Smith and Zsohar provide a number of other patient teaching techniques that can augment general therapeutic communication skills. One therapeutic teaching skill is the ability to assess a patient for individualized teaching. This requires the nurses to assess the patient’s education

TABLE 38–4 Therapeutic Communication Techniques

Technique	Description	Examples
Using silence	Accepting pauses or silences that may extend for several seconds or minutes without interjecting any verbal response.	Sitting quietly (or walking with the patient) and waiting attentively until the patient is able to put thoughts and feelings into words.
Providing general leads	Using statements or questions that (a) encourage the patient to verbalize, (b) choose a topic of conversation, and (c) facilitate continued verbalization.	“Tell me how it is for you.” “Perhaps you would like to talk about. . . .” “How might it help to discuss your feelings?” “Where would you like to begin?” “And then what?”
Being specific and tentative	Making statements that are specific rather than general and tentative rather than absolute.	“Rate your pain on a scale of 0 to 10” (specific statement) versus “Are you in pain?” (general statement) “You seem unconcerned about your diabetes” (tentative statement) versus “You don’t care about your diabetes and you never will” (absolute statement)
Using open-ended questions	Asking broad questions that lead or invite the patient to explore (elaborate, clarify, describe, compare, or illustrate) thoughts or feelings. Open-ended questions specify only the topic to be discussed and invite answers that are longer than one or two words.	“I’d like to hear more about that.” “Tell me about. . . .” “How have you been feeling lately?” “What brought you to the hospital?” “What is your opinion?” “You said you were frightened yesterday. How do you feel now?”
Sharing observations	The nurse openly informs the patient of the assessment and observations, especially those involving unconscious patient behavior.	“You are shaking.” “You are biting your nails.”

TABLE 38–4 Therapeutic Communication Techniques (*continued*)

Technique	Description	Examples
Restating or paraphrasing	Actively listening for the patient's basic message and then repeating those thoughts and/or feelings in similar words. This conveys that the nurse has listened and understood the patient's basic message and also offers patients a clearer idea of what they have said.	<p><i>Patient:</i> "I couldn't manage to eat any dinner last night—not even the dessert."</p> <p><i>Nurse:</i> "You had difficulty eating yesterday?"</p> <p><i>Patient:</i> "Yes, I was very upset after my family left."</p> <p><i>Patient:</i> "I have trouble talking to strangers."</p> <p><i>Nurse:</i> "You find it difficult talking to people you do not know?"</p>
Seeking clarification	<p>A method of making the patient's broad overall meaning of the message more understandable. It is used when paraphrasing is difficult or when the communication is rambling or garbled. To clarify the message, the nurse can restate the basic message or confess confusion and ask the patient to repeat or restate the message.</p> <p>Nurses can also clarify their own message with statements.</p>	<p>"I'm puzzled."</p> <p>"I'm not sure I understand that."</p> <p>"Would you please say that again?"</p> <p>"Would you tell me more?"</p> <p>"I meant this rather than that."</p> <p>"I'm sorry that wasn't very clear. Let me try to explain another way."</p>
Perception checking or seeking consensual validation	A method similar to clarifying that verifies the meaning of specific words rather than the overall meaning of a message.	<p><i>Patient:</i> "My husband never gives me any presents."</p> <p><i>Nurse:</i> "You mean he has never given you a present for your birthday or Christmas?"</p> <p><i>Patient:</i> "Well—not never. He does get me something for my birthday and Christmas, but he never thinks of giving me anything at any other time."</p>
Offering self	Suggesting one's presence, interest, or wish to understand the patient without making any demands or attaching conditions that the patient must comply with to receive the nurse's attention.	<p>"I'll stay with you until your daughter arrives."</p> <p>"We can sit here quietly for a while. We don't need to talk unless you would like to."</p> <p>"I'll help you dress to go home if you'd like."</p>
Giving information	Providing, in a simple and direct manner, specific factual information the patient may or may not request. When information is not known, the nurse states this and indicates who has it or when the nurse will obtain it.	<p>"Your surgery is scheduled for 11 a.m. tomorrow."</p> <p>"You will feel a pulling sensation when the tube is removed from your abdomen."</p> <p>"I do not know the answer to that, but I will find out from Ms. King, the nurse in charge."</p>
Acknowledging	Giving recognition, in a nonjudgmental way, of a change in behavior, an effort the patient has made, or a contribution to a communication. Acknowledgment may be with or without understanding, verbal or nonverbal.	<p>"You trimmed your beard and mustache and washed your hair."</p> <p>"I notice you keep squinting your eyes."</p> <p>"You walked twice as far today with your walker."</p>
Clarifying time or sequence	Helping the patient clarify an event, situation, or happening in relationship to time.	<p><i>Patient:</i> "I vomited this morning."</p> <p><i>Nurse:</i> "Was that after breakfast?"</p> <p><i>Patient:</i> "I feel like I have been asleep for weeks."</p> <p><i>Nurse:</i> "You had your operation Monday, and today is Tuesday."</p>
Presenting reality	Helping the patient differentiate the real from the unreal.	<p>"The doorbell sound came from the program on television."</p> <p>"I see shadows from the window coverings."</p> <p>"Your magazine is here in the drawer. It has not been stolen."</p>
Focusing	Helping the patient expand on and develop a topic of importance. It is important for the nurse to wait until the patient finishes stating the main concerns before attempting to focus. The focus may be an idea or a feeling; however, the nurse often emphasizes a feeling to help the patient recognize an emotion disguised behind words.	<p><i>Patient:</i> "My wife says she will look after me, but I don't think she can, what with the children to take care of. They're always after her about something—clothes, homework, what's for dinner that night."</p> <p><i>Nurse:</i> "Sounds like you are worried about how well she can manage."</p>
Reflecting	Directing ideas, feelings, questions, or content back to patients to enable them to explore their own ideas and feelings about a situation.	<p><i>Patient:</i> "What can I do?"</p> <p><i>Nurse:</i> "What do you think would be helpful?"</p> <p><i>Patient:</i> "Do you think I should tell my husband?"</p> <p><i>Nurse:</i> "You seem unsure about telling your husband."</p>
Summarizing and planning	Stating the main points of a discussion to clarify the relevant points discussed. This technique is useful at the end of an interview or to review a health teaching session. It often acts as an introduction to future care planning.	<p>"During the past half hour we have talked about . . ."</p> <p>"Tomorrow afternoon we may explore this further."</p> <p>"In a few days I'll review with you what you have learned about the actions and effects of your insulin."</p> <p>"Tomorrow, I will look at your feeling journal."</p>
Exploring	Investigating a patient's feeling related to a subject or idea.	<p>"Would you describe your experience with that in more depth?"</p> <p>"Tell me more about your childhood."</p>

and developmental level and also to determine what motivates the specific patient. Nurses can optimize the learning environment by turning off distractions and shutting the door, as well as sitting with the patient to create “space” for learning. Nurses should use effective teaching strategies such as demonstrating, involving the learner in the education process, and using videos for educational purposes. Nurses should confirm that their teaching efforts are understood. Nurses should ask themselves “Does my teaching reach the patient?” to help determine whether the patient is able to put the teaching into practice.

When nurses use reflection in the communication process, they are actively acknowledging what they have heard or seen from patients. *Reflecting* is what takes place when the nurse repeats the patient’s verbal or nonverbal messages for the patient’s benefit.

Reflecting Content

By reflecting the content of the message that the nurse receives from the patient, the nurse is essentially repeating the patient’s statement. This allows the patient the opportunity to both hear and reflect on what she has told the nurse in the course of the conversation.

The technique of content reflecting is often misused or overused in the mental health environment. Overuse of this technique causes it to lose effectiveness. The nurse should use this technique judiciously.

Clinical Example C

Jason Smith is a 48-year-old man who has been admitted to the hospital with the diagnosis of acute inferior myocardial infarction. He says to the nurse, “I can’t believe I had a heart attack. Those are for old people! I still feel young, but I guess I have to slow down.” The nurse, using reflection, asks Mr. Smith, “Do you feel that you can no longer lead an active life because you have had a heart attack?” The nurse’s statement will encourage Mr. Smith to continue sharing thoughts and explain why he believes this to be true. This will allow the nurse to correct any misunderstanding that he has about the recovery process after an MI.

Critical Thinking Questions

1. What physical attending communication techniques could be used in this interaction, and how might they impact the patient’s communication?
2. How might the nurse use acknowledging in this encounter? What impact do you think it would have on this interaction?
3. What other communication techniques could the nurse use, and how might those impact the interaction with Mr. Smith?

Reflecting Feelings

In using the technique of *reflecting feelings*, the nurse verbalizes the feelings that are implied in the patient’s comment. The nurse should respect that patients have the right to their own opinions and feelings even when the nurse personally disagrees with these. Some examples of reflecting feelings are as follows:

- “Sounds like you’re really angry at your sister.”
- “You’re feeling anxious about being discharged from the hospital later today.”

By reflecting feelings, the nurse attempts to identify any latent or connotative meanings that can either clarify or distort

the content that is communicated. Reflection of feelings is useful because it will encourage the patient to make additional, clarifying comments in the conversation.

Imparting Information

In *imparting information*, the nurse is helping the patient by supplying additional data for consideration. This encourages further clarification because it is based on new or additional input. Some examples of statements that impart information are as follows:

- “Group therapy will be held on Wednesday afternoon from 3:30 until 5:00.”
- “I am a mental-health nursing student.”

Note that it is inappropriate to withhold information from a patient when the patient asks an information-seeking question. The nurse must be mindful not to cross the line between giving information and giving the patient advice. Also, the nurse should not give information as a way of avoiding conflict. Nurses who give patients personal or social information are moving outside of the realm of therapeutic communication. Information that the nurse must share with the patient includes the nurse’s name, title, and position. New nurses must be cautioned to resist the temptation to divulge inappropriate information to patients.

The patient’s participation in the decision-making process begins with the patient taking in and understanding information regarding his own condition. The ultimate goal of sharing essential information with the patient is to provide effective education that empowers the patient. Empowered patients are more likely to achieve a positive mental health and physical health outcome. They are also less likely to be admitted for inpatient therapy or be readmitted after discharge.

Additional examples of therapeutic techniques, annotated with the techniques used by the nurse, are provided in **Box 38-4** ».

Avoiding Self-disclosure

Patients have been known to ask personal questions of nurses who are caring for them. This may include inquiring about the nurse’s marital status, where the nurse lives, what religion the nurse practices, or information about personal issues. The best methods for deflecting requests for self-disclosure, outlined by Auvil and Silver in their classic 1984 study, include the following:

- **Using honesty:** “I don’t feel comfortable sharing my address with you.”
- **Using benign curiosity:** “Why are you asking me this today?”
- **Using refocusing:** “You were talking about how your mother treats you. Why are you changing the topic? You were saying. . . .”
- **Using interpretation:** “I notice that every time you talk about your sister, you change the subject and ask me a question.” (pause)
- **Seeking clarification:** “You keep asking me where I live. I wonder if you have any concerns about me today?”

Box 38–4

Additional Examples of Therapeutic Communication

Example 1

Jeff Mastin, a 49-year-old man, is at the dermatologist's office having a basal cell carcinoma removed from his temple. Mr. Mastin teaches history and coaches baseball at the local high school. The procedure requires only a local anesthetic. Mr. Mastin's wife sits in a chair in the corner during the procedure. Dr. Keisha Thompson, the dermatologist, is conducting the procedure assisted by two nurses, Sheila Webber and Karl Kline. Ms. Webber's son is on the baseball team, and much of the conversation during the procedure revolves around baseball.

As Dr. Thompson finishes the procedure, Mr. Kline begins giving discharge instructions.

"You need to keep the bandage dry and intact for 48 hours. It's also important to minimize movement for 48 hours." **<giving information>**

"His baseball bag is in the trunk of the car, and he's planning on dropping me off at the house and going on to practice this afternoon." Ms. Mastin says.

"I understand you don't want to miss practice," Ms. Webber says, **<acknowledging>** "but the reason for limiting movement for 48 hours is because strenuous activity increases the risk of bleeding." **<being specific>**

Example 2

Junot Martinez, a 62-year-old man, is a professor of anthropology at the local college, and he was admitted to the hospital yesterday to have a noncancerous astrocytic brain tumor removed. Mr. Martinez just regained consciousness after being under anesthesia for many hours, and he is disoriented, asking disjointed questions of family, friends, and members of healthcare team. Clark Karabell, the nurse on duty, checks on Mr. Martinez during the period of his greatest confusion. Mr. Martinez has been mumbling for quite a few hours but eventually he poses a question to Mr. Karabell, "I feel like I've been asleep forever. How long have I been here?"

"You were admitted to the hospital yesterday morning, Mr. Martinez," Karabell responds. "That was Thursday morning, and now it is 4 p.m. on Friday." **<clarifying time>**

"Which one of you people stole my wallet?" Martinez asks, agitated.

"No one stole your wallet, Mr. Martinez," Karabell responds. "Your wife has your wallet, and she is downstairs at the food court right now." **<presenting reality>**

"Well, I guess nobody is looking out for me, then," Martinez says, looking downcast.

"Would you like me to stay with you until she returns?" Karabell asks. **<offering self>**

Example 3

Shuka Mansoori, a 50-year-old woman, is being released from the hospital following a heart attack. She is in a room with her husband, Blake, and seems withdrawn and moody despite being described normally as a sociable person. Francine Muhly, the nurse on duty, provides patient teaching on post-heart attack lifestyle changes when Ms. Mansoori unexpectedly asks, "Am I going to be okay?"

Ms. Muhly responds, "What specifically are you worried about, Ms. Mansoori?" **<seeking clarification, using open-ended questions>**

"I'm worried that I won't be able to play with the grandkids. I'm worried that I'm going to die," she says.

"So you're worried that you won't be able to do the things you enjoy and that you might have another heart attack?" Ms. Muhly summarizes. **<restating>**

"Yes," Ms. Mansoori says.

"I understand your concerns. However, if we work together to make a few simple changes to your diet, exercise routine, and smoking habit," Ms. Muhly says, "your overall health will improve. This will help reduce your risk of additional cardiovascular problems." **<planning>**

Example 4

Shen Liao, an 8-year-old boy, is admitted to the emergency department with significant bruising on his body. He is accompanied by his mother, Anya, and his 3-year-old sister, Laura. When asked how he received the bruises, Shen is silent, but his mother provides the explanation that he fell down a flight of stairs while playing with his younger sister.

Dave Musharraf, the nurse, is suspicious that the patient may have received the injuries through abuse, because most of the bruises are concentrated on the patient's back and forearms. He asks Shen and his mother, "Could you tell me more about the accident?" **<using open-ended questions, exploring>**

"Well," Mrs. Liao says, "he was at the top of the stairs and . . . tripped over a playground ball."

Musharraf turns to Shen and says "Shen, I'd like to hear your explanation. Could you tell me how the accident happened?" Musharraf then sits quietly while waiting for Shen to respond.

<using silence>

"My dad hit me," Shen says quietly, looking away as his mother recoils.

"Thank you for telling me that, Shen," **<acknowledging>** responds Musharraf. "Can you tell me exactly what happened?" **<exploring>**

- **Responding with feedback and limit setting:** "I'm uncomfortable when you ask me who pays my tuition for school. Talking about my finances isn't part of our agreement to work together." Adding something like "The last time we met, you were deciding whether you were going to call your sister on the phone . . ." helps restructure the situation.

These communication techniques should be used within the context of the therapeutic relationship.

Therapeutic communication revolves around the needs of the patient. It is not appropriate for the nurse to talk to the patient about her experiences, such as what she did last night or her thoughts on a given subject. This wastes time

that could be spent on learning about the patient's needs, thoughts, concerns, or problems. The nurse should always maintain a patient focus during communication.

Clarifying

Even when the nurse has listened carefully and thoughtfully to the patient, there may be a need to clarify information. *Clarifying* is an attempt to understand the basic nature of a patient's statement.

- "I'm confused about what is upsetting you. Could you go over that again, please?"
- "You say you're feeling anxious now. What's that like for you?"

Asking the patient to give an example allows the patient to clarify the meaning of the communication and helps the nurse understand the intended message. Clarification may be needed because of the language that the patient employs, such as slang used by adolescent patients, or when the nurse is not certain of adequate interpretation of what the patient is trying to convey.

Clinical Example D

The nurse is caring for Sara Kim, a 36-year-old woman who was recently diagnosed with breast cancer. The physician has informed Ms. Kim that her chance of full recovery is excellent and has recommended a course of treatment to include removal of the involved breast followed by chemotherapy. While the nurse is providing preoperative instructions, Ms. Kim says, "I'll sign the consent form, but I'll be dead before the surgery date." The nurse is not sure whether Ms. Kim is fearful of dying from cancer or whether this may be a statement of suicidal ideation. The nurse seeks clarification by asking, "Why do you think you'll be dead before the date for surgery arrives?"

Critical Thinking Questions

1. What would be an appropriate next step if Ms. Kim clarifies that she is considering suicide?
2. What would be an appropriate next step if Ms. Kim clarifies that she believes she will die from the cancer before the surgery can take place?
3. What is another therapeutic communication tactic that the nurse could have used instead of clarifying? How might the outcome have been changed with the use of a different technique?

Paraphrasing

By *paraphrasing*, the nurse restates in her own words what the patient has said. Some examples of paraphrasing statements are as follows:

- "In other words, you're tired of being treated like a child."
- "I hear you saying that when people compliment you, you feel embarrassed and if they knew the real you, they would not provide such praise."

The nurse is able to test her understanding of what the patient is trying to communicate through paraphrasing. Paraphrasing is reflective in nature as it lets the patient know what the nurse heard and how the nurse understands what is being discussed. It is also an opportunity for the patient to clarify the content of the message or the feelings behind it.

Checking Perceptions

Nurses can *check perceptions* by sharing how they perceived and heard the information. Once the nurse's perceptions have been shared, it is important to ask the patient to verify the perception, by using statements such as the following:

- "Let me know if this is how you see it, too."
- "I get the feeling that you're uncomfortable when we're silent. Does that seem right?"

The effective use of perception checking conveys that the nurse wants to understand what the patient is communicating.

It gives the patient the opportunity to correct inaccurate perceptions that the nurse may have. Essentially, *checking perceptions* allows the nurse to avoid actions that are based on false assumptions about the patient.

Questioning

Questioning is a very direct way of speaking that the nurse can use when communicating with a patient. This technique is quite useful when the nurse is seeking specific information. If the nurse is trying to engage in meaningful dialogue with a patient, questions should be limited, because they can affect the nature and the ranges of responses from the patient.

Open-ended questions can be used to elicit more information than closed questions. An *open-ended question* allows the nurse to focus the topic while allowing the patient freedom with responses. Examples of this include the following:

- "How did you feel when your brother said that to you?"
- "What's your opinion about . . . ?"

Closed questions should be used sparingly because they typically limit the patient's responses to "yes" or "no." Closed questions also limit therapeutic exploration. This type of question can be useful, however, for the patient who may have disorganized thinking. Closed questions can be used to guide these patients.

Questions that ask "why" are typically less helpful than open-ended questions. These questions tend to be hard to answer, in part because they require a higher level of insight on the part of the patient, and they rarely lead to the nurse having a clearer understanding of the current situation. Other types of closed questions, such as "who," "what," "when," and "how," can be useful if the nurse uses them wisely.

Nurses must be careful when questioning not to steer the patient to answer questions in a certain way. For example, "You don't exercise in excess, do you?" may suggest that the patient answer this question with a "no." Refer to the module on Assessment for more information on using open-ended and closed questions.

Structuring

The nurse can use a technique known as *structuring* in an attempt to create order or establish guidelines for patients. This helps patients become aware of their problems and the order in which they should deal with them. Examples of structuring statements are as follows:

- "You've mentioned that you want to improve your relationships with your husband, your son, and your boss. Let's put them in order of importance."
- "No, I won't be giving you advice, but we can discuss some solutions to these issues together."

The nurse can use structuring when a patient introduces a number of issues in a brief period and doesn't know where to begin. This technique can also be used to define the parameters of the nurse-patient relationship in terms of how the nurse will participate with the patient to facilitate the problem-solving process.

Pinpointing

The nurse can use a technique known as *pinpointing* to call attention to specific statements and relationships. For example, when the nurse points out inconsistencies among statements or similarities and differences in points of view, feelings, or actions, the nurse is engaging in pinpointing. This can also be used to determine differences between what an individual says and what one does. Examples of pinpointing statements include the following:

- “So, you and your husband aren’t in agreement about how many children you want.”
- “You say you’re happy, but you’re frowning.”

Linking

When using the technique known as *linking*, the nurse responds to the patient in a way that ties together events, experiences, feelings, or people. Nurses often use linking to connect past experience with current behaviors that the patient is exhibiting. The nurse can also use linking when there is tension between two individuals during times of stress. Examples of statements that use linking include the following:

- “You felt depressed after the death of both of your parents.”
- “So, the arguments didn’t really begin until after you lost your job.”

Giving Feedback

In using *feedback*, the nurse shares reactions to the patient’s statements or behaviors. This technique can help a patient become aware of how their own actions and behaviors can affect others. The nurse who responds with feedback may engage in therapeutic self-disclosure because it allows the nurse to offer constructive information regarding how the patient’s words or actions have affected the nurse as a

communication partner. Total self-disclosure, however, is inappropriate in the nurse–patient relationship and should be avoided. This can place a burden of interdependence on the patient and may limit the time and energy the nurse has available to work on the patient’s concerns. The use of reciprocal self-disclosure is more appropriate in friend and colleague relationships than in nurse–patient relationships.

Effective feedback should have three distinct qualities. It should be *immediate*, meaning that it is given as soon as possible; it should be *honest*, meaning that it provides a true reaction; and it should be *supportive*, meaning that it is provided in a way that is tolerable to comprehend and never hurtful or disrespectful to the patient. Examples of effective feedback statements include the following:

- “When you cross your arms while speaking, I feel your apprehension.”
- “Sometimes when you look down while we are talking, I think you’re angry.”

Feedback should always be provided to the patient in a nonthreatening manner. Threatening feedback may increase the patient’s defensiveness. The more defensive the patient is when engaging in therapeutic communication, the less able the patient is to hear and understand the feedback that the nurse is providing. Patients often feel offended if they perceive the nurse to be rejecting them. Feedback that is nontherapeutic, meaning that it is harsh, hurtful, cruel, or rejecting of the patient, will create an unnecessary boundary between the patient and the nurse. The nurse should take great care to prevent the patient from feeling personally rejected as a result of feedback from the nurse. **Table 38-5** » lists strategies and rationales that the nurse can use for giving helpful, nonthreatening feedback.

Feedback goes both ways. Patients usually want to accomplish several items during their interactions with the

TABLE 38-5 Giving Helpful, Nonthreatening Feedback

Strategy	Rationale
Focus the feedback on behavior.	Feedback should relate to what the patient actually does rather than how the nurse imagines the patient to be.
Focus the feedback on observations.	Feedback should relate to what the nurse actually sees or hears the patient do. When inferences are used rather than observations, the nurse is drawing conclusions or making assumptions.
Focus the feedback on description.	Description reports what actually occurred rather than evaluating it in terms of good or bad, right or wrong.
Focus feedback on “more or less” rather than “either/or” descriptions of behaviors.	“More or less” descriptions stress quantity rather than quality (which may be value laden).
Focus feedback on here-and-now behavior rather than there-and-then behavior.	The most meaningful feedback from the nurse is given as soon as it is appropriate to do so.
Focus feedback on sharing of information and ideas.	Sharing of ideas and information helps the patient make decisions about the patient’s own well-being. In contrast, by giving advice, the nurse takes away the patient’s freedom to be self-determining.
Focus feedback on exploration of alternatives.	Focusing on a variety of alternatives for accomplishing a particular goal for the patient prevents premature acceptance of answers or solutions that may not be appropriate.
Focus feedback on its value to the patient.	Feedback should serve the patient’s needs, not the needs of the nurse.
Limit feedback to the appropriate amount of information.	Overload of information will decrease the effectiveness of feedback for the patient.
Limit feedback to the appropriate time and place.	For feedback to be effective, it must be presented at the appropriate time.
Focus feedback on what is said rather than why it is said.	Focusing on why the patient has said something or done something moves away from observations and toward patient motive or intent. Motive or intent can only be assumed and, unless verified, such an assumption is counterproductive.

Box 38–5

Reflecting on Feedback from Patients

Input can be both positive and negative. Input can be received from a wide variety of individuals, including classmates, instructors, and patients. Input can allow the nurse to become more aware of “blind spots,” that is, those characteristics about the self that are ignored, denied, or defended. Self-deception can interfere with the nurse’s ability to relate and to communicate. Strategies to increase self-awareness include:

- Think about recent interactions with patients and how those patients responded to you.
- Identify the positive/negative elements in these interactions.
- Try to determine what the patients were telling you about yourself in the interactions. Ask these questions: What characteristics do you possess that enable patients to openly express their thoughts and feelings? What characteristics do you possess that prevent patients from openly expressing their thoughts and feelings?
- Discuss the interactions and your interpretations of them with an instructor, mentor, or preceptor.
- Ask for feedback on your behavior from others.

nurse. They want to express themselves, and they want to express information about their perception of the nurse. The nurse should be open and receptive when receiving cues from the patient, either solicited or unsolicited, because these can be useful in a more meaningful working relationship. **Box 38–5** » provides strategies to help nurses reflect on feedback from patients.

Confronting

Used in a constructive way, confrontation can lead to productive change. *Confronting* is defined as the deliberate invitation to examine some aspect of personal behavior. Typically, confronting is used when there is a discrepancy or incongruence between what an individual says and what that individual does. It can also be used when expected behavior differs from actual behavior, such as when a patient who is prescribed a liquid diet asks family members to sneak in food from a restaurant. Confrontation requires careful attention to nonverbal communication and to both verbal and nonverbal discrepancies between messages.

The two basic types of confrontation are informational and interpretive. Each type can be directed toward the patient’s resources and limitations. An *informational confrontation* describes the visible behavior of another individual (e.g., “You look sad and say you’re ‘not as smart as your brother and a sister,’ yet you are the only one who made the honor roll”). *Interpretive confirmation* expresses thoughts and feelings about behavior and draws inferences (e.g., “Ever since Emily and Frank criticized the way you conducted the assembly, you haven’t spoken to them. It looks like you’re feeling angry”).

Six skills can be used in incorporating constructive confrontations:

1. Use personal statements with the words *I*, *my*, and *me*.
2. Use relationship statements that express thoughts and feelings about the patient in the present.

3. Use statements that describe visible patient behaviors. This is known as behavior descriptions.
4. Use the description of personal feelings in which you specify the feeling by name.
5. Use responses that are aimed at understanding. Examples of these include paraphrasing and perception checking.
6. Use constructive feedback skills.

Summarizing

Summarizing is a technique that the nurse can use to highlight the main ideas that are expressed during interactions. It is used to convey the nurse’s understanding to the patient, and it allows both nurse and patient to benefit from a review of the main ideas of a conversation. Summarizing can also be useful when the nurse wants to focus the patient’s thinking and to aid in conscious learning.

In certain instances, summarizing is particularly appropriate. The nurse may want to use this technique in the first few minutes of patient interaction, because it is useful to review what occurred during previous interactions. This helps the patient recall items that were discussed and gives the patient an opportunity to see how the nurse synthesized the information from previous encounters. Summarizing also keeps all participants directed toward a common goal.

Processing

The nurse can also use a technique known as processing. *Processing* is a complex and sophisticated technique used to direct attention to the interpersonal dynamics of the nurse–patient relationship in terms of content, feelings, and behaviors that have been expressed. This is an advanced skill. Processing is most useful and meaningful when therapeutic intimacy has been achieved.

Clinical Example E

The nurse is preparing to conduct a home visit to Emily Bardinovich, an 86-year-old woman who has lived in an assisted living apartment for the past 5 years. Mrs. Bardinovich was recently discharged back to her apartment following an exacerbation of COPD. The nurse has cared for Mrs. Bardinovich for many years and knows her as a friendly, outgoing woman with a great sense of humor who loves to tease people. Today, the nurse finds Mrs. Bardinovich very quiet and reserved with little to say. The nurse comments, “You’re very quiet today; you haven’t teased me at all,” to which Mrs. Bardinovich responds, “I’m just not in the teasing mood.” The nurse has used processing to help the patient begin to talk about how she feels. This will allow the nurse to perform a more in-depth assessment of the patient’s mood and thoughts.

Critical Thinking Questions

1. What therapeutic communication strategies could the nurse use to respond to the patient’s statement, “I’m just not in the teasing mood?”
2. What are some potential outcomes if the nurse does not ask Mrs. Bardinovich why she is being so quiet?
3. Describe how the outcome might differ if the nurse uses linking instead of processing in this situation.

Common Mistakes

Nurses often make mistakes when it comes to therapeutic communication. It can be difficult for the nurse to both

empathize and communicate with patients when the nurse is feeling uncomfortable with the situation. In addition to the barriers to communication discussed earlier and outlined in Table 38–1, some common mistakes the nurse should take care to avoid include the following:

- **Giving advice.** This carries the message that the patient is not capable of solving problems.
- **Minimizing or discounting feelings.** Attempts at reassurance often minimize and discount what the patient is feeling.
- **Deflecting.** Changing the subject or making jokes in an attempt to move the conversation to something that is less painful is not considered a positive shift because it gives the patient the message that the nurse does not know how to cope with the patient's experience.
- **Interrogating.** Asking a series of questions implies that the nurse is more interested in gaining information than in listening to what the patient has to say.
- **Sparring.** Debating or disagreeing with the patient sets up an adversarial dynamic and prevents the nurse from listening to what the patient is trying to communicate.

Clinical Example F

Anita Alvarez, a nurse, is providing care to Mark Walton, a 27-year-old man who has just been diagnosed with irritable bowel syndrome (IBS). Anita is teaching Mr. Walton about the dietary changes that he will need to make to manage his condition. Anita asks a series of questions quickly, changing the subject rapidly and not allowing Mr. Walton to provide answers or ask clarifying questions. During the session, she reads directly off a computer screen. When Mr. Walton does get a chance to ask questions, Anita takes several seconds to respond because she is busy looking at her phone. She focuses on herself for several minutes when Mr. Walton asks one question about her work. When Mr. Walton leaves, Anita says, "Everything's going to be all right" as she slams the door.

Critical Thinking Questions

1. Which mistakes or barriers to communication did Anita engage in?
2. What could Anita have done better or differently to ensure that Mr. Walton retained the information and to promote the therapeutic relationship?

The Therapeutic Relationship

Nurse–patient relationships are referred to by some as interpersonal relationships, by others as therapeutic relationships, and by still others as helping relationships. Helping is a growth-facilitating process that strives to achieve two basic goals (Egan, 2013):

1. Help patients manage their problems of living more effectively and develop unused or underused opportunities more fully.
2. Help patients become better at helping themselves in their everyday lives.

A therapeutic relationship may develop over weeks of working with a patient or within minutes. The keys to a therapeutic relationship are the development of trust and

acceptance between the nurse and the patient and an underlying belief that the nurse cares about and wants to help the patient.

The therapeutic relationship is influenced by the personal and professional characteristics of the nurse and the patient. Age, sex, appearance, diagnosis, education, values, ethnic and cultural background, personality, expectations, and setting can all affect the development of the nurse–patient relationship. Consideration of all of these factors, combined with good communication skills and sincere interest in the patient's welfare, enables the nurse to create a therapeutic relationship. A therapeutic relationship:

- Is an intellectual and emotional bond between the nurse and the patient and is focused on the patient.
- Respects the patient as an individual, including the following:
 - (a) Maximizing the patient's abilities to participate in decision making and treatments
 - (b) Considering the patient's ethnic background and cultural practices
 - (c) Considering family relationships and values.
- Respects patient confidentiality.
- Focuses on the patient's well-being.
- Is based on mutual trust, respect, and acceptance.

Phases of the Therapeutic Relationship

The therapeutic relationship process can be described in terms of four sequential phases: the preinteraction phase, introductory phase, working (maintaining) phase, and termination phase. Each phase is characterized by identifiable tasks and skills, and the relationship must progress through the stages in succession because each builds on the one before. The nurse can identify the progress of a relationship by understanding these phases.

Preinteraction Phase

The preinteraction phase is similar to the planning stage before an interview. In most situations, the nurse has information about the patient before the first face-to-face meeting. This information may include the patient's name, address, age, medical history, and/or social history. Planning for the initial visit may generate some anxious feelings in the nurse. If the nurse recognizes these feelings and identifies specific information to be discussed, positive outcomes can evolve.

Introductory Phase

The introductory phase, also referred to as the orientation phase or the pretherapeutic phase, sets the tone for the rest of the relationship. During this initial encounter, the patient and the nurse closely observe each other, and each forms judgments about the other's behavior. The goal of the nurse in this phase is to develop trust and security within the nurse–patient relationship (Boyd, 2014).

During the initial parts of the introductory phase, the patient may display some resistive behaviors. *Resistive behaviors* are those that inhibit involvement, cooperation, or change. These behaviors may arise from the patient's difficulty in acknowledging the need for help, fear of exposing

and facing feelings, anxiety about the discomfort involved in changing problem-causing behavior patterns, and fear or anxiety in response to the nurse's approach, which may, in the patient's opinion, be inappropriate.

The nurse can overcome a patient's resistive behaviors by conveying a caring attitude, genuine interest in the patient, and competence. This will help the nurse foster the development of trust in the relationship. **Trust** can be described as a reliance on someone without doubt or question, or the belief that the other individual is capable of assisting in times of distress and in all likelihood will do so. To trust another individual involves risk; patients become vulnerable when they share thoughts, feelings, and attitudes with the nurse. Trust, however, enables the patient to express thoughts and feelings openly.

By the end of the introductory phase, patients should begin to do the following:

- Develop trust in the nurse.
- View the nurse as a competent professional capable of helping.
- View the nurse as honest, open, and concerned about the patient's welfare.
- Believe the nurse will try to understand and respect the patient's cultural values and beliefs.
- Believe the nurse will respect patient confidentiality.
- Feel comfortable talking with the nurse about feelings and other sensitive issues.
- Understand the purpose of the relationship and the respective roles of the patient and nurse.
- Feel like an active participant in developing a mutually agreeable plan of care.

Clinical Example G

While working in an ambulatory care setting, the nurse is asked by the physician to talk with a 24-year-old female patient named Raissa Kunin to explain the need for phlebotomy secondary to Ms. Kunin's diagnosis of polycythemia. Ms. Kunin's hemoglobin is 17.4 mg/dL; it has been steadily increasing since 1 year ago, when it was 16.2 mg/dL. The nurse enters the room and says, "Hello, Ms. Kunin, my name is Mikela Mathews. I'm a registered nurse working for Dr. Shah. He asked me to speak with you about the need to remove blood to lower your hemoglobin." Ms. Kunin says, "I'm just not sure I want to do that, but I'll call you after I have time to think about it." The nurse responds by stating, "You have every right to make a decision in your own best interest. What if I just give you some information while you're here so you can make your decision based on all the details. I can explain the risks of polycythemia, the process of removing blood, and answer any questions you may have." The nurse attempts to overcome resistance behavior by allowing the patient to maintain control. This also promotes a trust-relationship with the patient.

Critical Thinking Questions

1. How would you respond if the patient answered, "No, thank you. That's not necessary. I can look it up on the internet"?
2. If the patient agrees to listen to the nurse, what phase of the relationship will they be in once the nurse begins teaching?
3. What other types of resistive behaviors might you encounter, and how would you attempt to overcome them?

Working Phase

The working phase has two major stages: exploring and understanding thoughts and feelings, and facilitating and taking action. In this phase, the nurse helps the patient explore thoughts, feelings, and actions and plan a program of action to meet preestablished goals.

The nurse must have the following skills for this phase of the therapeutic relationship:

- **Empathetic listening and responding.** As discussed previously, the nurse must listen attentively and respond in ways that indicate that the nurse acknowledges the patient's concerns and feelings as important. Nonverbal behaviors indicating empathy include moderate head nodding, a steady gaze, moderate gesturing, and little activity or body movement.
- **Respect.** The nurse must show respect for the patient's willingness to be available, a desire to work with the patient, and a manner that conveys that the nurse takes the patient's point of view seriously.
- **Genuineness.** The nurse exudes genuine care for the patient by maintaining professional behaviors that promote the therapeutic helping relationship. Egan (2013) has outlined five behaviors that are components of genuineness: not taking refuge or overemphasizing the role of counselor, being spontaneous, being nondefensive, being consistent, and being capable of appropriate self-disclosure.
- **Concreteness.** The nurse must encourage the patient to be concrete and specific rather than to speak in generalities. When the patient says, "My blood pressure has been very unstable," the nurse narrows the topic to the specific by replying, "Show me your blood pressure log for the past 2 weeks."
- **Reflecting, paraphrasing, clarifying, and confronting.** These skills, as described earlier, assist nurses in making sure they understand the patient's messages and feelings and help the patient to identify discrepancies that inhibit the patient's self-understanding or exploration of specific areas and ideas.

During this first stage of the working phase, the intensity of interaction increases, and the patient may express or demonstrate feelings such as anger, shame, or self-consciousness. If the nurse is skilled in this stage and the patient is willing to pursue self-exploration, the outcome is a beginning understanding on the part of the patient about behavior and feelings.

Patients with dementia or cognitive impairments may not move between phases of the nurse-patient relationship in the same way as patients with normal cognitive function. Nurses working with these patients often find a need to reintroduce themselves at each meeting.

Termination Phase

The termination phase of the relationship is often expected to be difficult and filled with ambivalence. However, if the relationship has evolved effectively through the previous phases, the patient generally has a positive outlook and feels able to handle problems independently. On the other hand, because caring attitudes have developed, it is natural to

expect some feelings of loss, and each individual in the relationship needs to develop a way of saying good-bye.

Many methods can be used to terminate relationships. Summarizing or reviewing the process can produce a sense of accomplishment. This may include sharing reminiscences of how things were at the beginning of the relationship and comparing them to how they are now. It is also helpful for both the nurse and the patient to express their feelings about termination openly and honestly. Thus, termination discussions need to start in advance of the termination interview. This allows time for the patient to adjust to independence. In some situations, referrals are necessary, or it may be appropriate to offer an occasional standby meeting to give support as needed. Follow-up phone calls or emails are other interventions that can ease the patient's transition to independence.

Developing Therapeutic Relationships

Whatever the practice setting, the nurse develops a therapeutic relationship in which to establish mutual goals (outcomes) with the patient or, if the patient is unable to participate, with support people. Although special training in counseling techniques is advantageous, there are many ways of helping patients that do not require special training:

- **Listen actively.** Active listening allows the nurse to gather pertinent information about the patient's physical and emotional health, and it also conveys that the nurse is fully interested in what the patient has to say.
- **Help identify what the person is feeling.** Patients who are troubled are often unable to identify or label their feelings and consequently have difficulty working them out or talking about them. Responses such as "You seem angry about your diagnosis" or "You sound as if you've been lonely since your wife died" can help patients recognize what they are feeling and talk about it.
- **Put yourself in the other person's shoes (i.e., empathize).** Communicate to the patient in a way that shows an understanding of the patient's feelings and the behavior and experience underlying these feelings.
- **Be honest.** In an effective relationship, the nurse honestly recognizes any lack of knowledge by saying "I don't know the answer to that right now;" can openly discuss the nurse's own discomfort by saying, for example, "I feel uncomfortable about this discussion;" and can also admit tactfully that problems do exist, for instance, when a patient says "I'm a mess, aren't I?"
- **Be genuine and credible.** Patients will sense whether you are truly concerned.
- **Use your ingenuity.** Consider all of the available actions when handling problems. Whatever course is chosen needs to further the achievement of the patient's goals (outcomes), be compatible with the patient's value system, and offer the probability of success.
- **Be aware of cultural differences that may affect meaning and understanding.** To facilitate nurse-patient interactions, recognize the language(s) and/or dialect(s) the patient uses. Provide a bilingual interpreter as needed for patients with limited English language ability.

- **Maintain patient confidentiality.** To maintain the patient's right to privacy, share information only with other healthcare professionals as needed for effective care and treatment.
- **Know your role and your limitations.** Clarify functions and roles, specifically what is expected of the patient, the nurse, and the primary care provider. Every individual has unique strengths and problems. When you feel unable to handle some of the patient's problems, you should inform the patient of this and refer the patient to the appropriate health professional.

Lifespan Considerations

Communicating with Children and Families

In caring for pediatric patients, the nurse should implement interventions that will establish an effective nurse-child-family relationship. The nurse must provide an appropriate environment that will foster nurse-child-family communication and ensure confidentiality while doing so. The techniques the nurse uses to develop this relationship are similar to the techniques that the nurse uses with an individual patient, tailoring communication techniques to the needs of both the child and the family (**Figure 38-9** »).

The nurse can use any of several communication techniques with children. These include accepting, active listening, broad openings, clarifying, collaborating, exploring, focusing, giving recognition, observation, offering self, placing an event in time or sequence, reflection, restating or paraphrasing, summarizing, and validating perceptions. The nursing implications for each technique are explored in **Table 38-6** ».

Establishing Rapport with Children

First and foremost, the nurse must establish rapport with the child to set the stage for a productive therapeutic relationship. All patients, including children, will be more responsive to

Figure 38-9 » Taking time to listen to the child and family members is important for establishing trust and developing rapport.

TABLE 38–6 Nursing Implications of Using Therapeutic Communication Techniques with Children

Communication Technique	Nursing Implications
Accepting	By conveying acceptance, the nurse respects the child's emotions and allows the child to cry when in pain or lets the child know that crying is okay.
Active listening	The nurse involves the child in the discussion and encourages the child to communicate his point of view. It is important to face the child and parents when speaking. This conveys to the family that the nurse is listening and understands what is being said.
Broad openings	This includes using open-ended questions that allow the child to choose the topic for discussion.
Clarifying	By asking the child to clarify or elaborate on what is being expressed, the nurse communicates understanding.
Collaborating	The nurse suggests collaboration with the child and family and then assists them through the problem-solving process.
Exploring	This helps the child to organize their thoughts and focus on the current issue. It will also encourage the child to discuss the issue in more detail.
Focusing	This guides the direction of the conversation. It is useful with small children who may wish to discuss a variety of topics.
Giving recognition	This identifies observed behaviors and indicates an interest in the child.
Observation	This is particularly important with the behavioral aspect of communication. The nurse acknowledges behaviors that indicate the child's thoughts and feelings.
Offering self	This indicates that the nurse is available and willing to listen to the child.
Placing the event in time or sequence	The goal of this technique is to help the child and the nurse understand the order of events.
Reflection	This indicates that the nurse is interested in the discussion and also validates the child's concerns.
Restating or paraphrasing	This acknowledges to the child that the nurse is listening. It also validates appropriate interpretation of what the child is communicating.
Summarizing	This highlights the key facts of the conversation and also provides an opportunity to consider direction for future discussions. It can also provide closure. Summarizing can occur at varying points in the communication process.
Validating perceptions	This is when the nurse shares conclusions that have been drawn as a result of the discussions with the child. It provides an opportunity for the child to confirm or deny interpretations that the nurse has made throughout the process.

the nurse who makes an effort to help the patient feel that they are important in an interaction. The following guidelines can be used by the nurse to establish rapport with a child and encourage the sharing of information and feelings:

- **Position yourself on the same eye level as the child.** This suggests to the child that the nurse cares about and respects the child.
- **Show interest in what the child is doing.** This displays that the nurse is interested and encourages security.
- **Agree with the child when it is appropriate.** It may be appropriate for the nurse to share feelings. An example of this is telling the child, "I don't like the taste of that medicine either, but sometimes I have to take it when I am sick—but then I drink something that I like." Sharing experiences with the child offers encouragement to the child and family.
- **Compliment the child.** Examples include "You are really strong" or "You picked really nice colors for that picture." Complimentary statements by the nurse may reduce anxiety while conferring status on the child.
- **Use a calm tone of voice and language that is developmentally appropriate.** It is important to talk and share information with children that is on an appropriate level of comprehension.
- **Pace the discussion or procedure so that the child does not feel rushed.** Feeling rushed will increase the child's anxiety.

- **Explain concepts in terms the child can understand.** This is especially important for preschool-age children, who have a limited concept of time. For example, stating "Your mother will be back after lunch" is appropriate for this age level because it provides a concrete time frame that the child can understand.
- **Include the child in the discussion of care if developmentally appropriate.** This is particularly important for adolescents, because they have the cognitive ability to participate in abstract conversation and to comprehend some medical terminology.
- **Listen more than you talk, and avoid distractions.** This shows the child that the nurse is interested in what the child has to say.

Establishing Trust with Children and Families

Trust is critical to an effective nurse–child–family relationship. Strategies to establish trust with children and families include following through on promises made to the child and family, respecting confidentiality, and being truthful, even when the truth is not what they want to hear.

If a child asks whether a procedure is painful, answer truthfully, but follow with positive words. For example, if a child asks if his "shot" is going to hurt, you might reply, "Yes, most people say that a shot hurts, but it will hurt only for a moment, and then it will be over. Your mother can hold your hand while I give you the shot if that will make you feel better." By following difficult information with a

positive rationale or comforting statement, the nurse can maintain credibility while still providing compassionate care.

Communicating with Pregnant Women

Whether a pregnancy is planned or unplanned, the patient is likely to experience stress and emotional distress. Therapeutic communication with pregnant women is especially important because the woman's emotional and physical health—as well as the health of the child—is at stake during pregnancy (Goodtherapy.org, 2016). Sources of emotional distress during pregnancy include worries about the health of the child, independent mental health issues such as anxiety and depression, strained romantic partnerships, financial issues, and physical challenges. Physical health issues include fetal development, physical strain on the mother, proper nutrition, and many others outlined in the Reproduction module.

Keys to communicating with pregnant women are relating medical information clearly and listening for patient questions and concerns. Nurses should use active listening techniques to be attentive to the patient's verbal and nonverbal communication. Silence can be a powerful tool to allow the patient to express herself fully so the nurse can address her concern. Making observations fills a similar role in that it allows the patient to communicate without the need for lengthy questioning. For example, the nurse can make observations such as "You look tired" to solicit communication by the patient. Using therapeutic communication techniques can help clarify patient concerns and protect the health of both mother and child.

Communicating with Older Adults and Their Families

Most older adults respond well to the therapeutic communication strategies outlined above. However, many older adults suffer from conditions that make communication difficult and require the nurse to adjust the therapeutic communication strategy (Potter et al., 2013). Approximately half of older adults suffer from hearing loss, and many also suffer from vision loss. These sensory impairments require the nurse to select communication techniques specifically tailored to the needs of the individual

older adult. For example, a nurse can change the environmental conditions of the individual with hearing loss to promote effective communication. Many of the difficulties in communicating effectively with older adults arise when the nurse and patient fail to establish a reliable nurse–patient communication system. The nurse can overcome communication impairments of all kinds by researching assistive communication devices and involving the patient's family in the communication process.

Establishing a reliable communication system with an older adult requires the nurse to continuously reevaluate the patient's communication needs. For instance, for a patient with a cognitive impairment such as dementia, the nurse can use simple, concrete sentences, ask one question at a time, allow time for the patient to reflect, be an active listener, and include family in conversation to ease the burden on the patient. For patients who are visually impaired, nurses can check for use of glasses, identify themselves when coming into contact with the patient, speak in a normal tone of voice, seldom use gestures, and employ fonts of readable size in printed materials. If the patient seems to not understand the nurse's questions or teaching, the nurse can reevaluate whether she can take any specific steps to change the communication pattern, such as moving to a different room or involving another member of the healthcare team. To communicate most effectively with the older patient, nurses should acquaint themselves with the patient's family and friends to learn about relevant health concerns and favorite conversational topics.

Conclusion

Whether teaching, advocating, assessing, planning, documenting, or intervening, the nurse requires strong communication skills. The ability to communicate effectively plays a large role in the nurse's ability to deliver the highest quality of care to patients. Whether communicating with patients, other members of the healthcare team, distraught family members, or peers, nurses need to be understood and understand the messages they receive. Strong verbal and written communication skills are required of the effective nurse, who must also monitor nonverbal communication to maintain consistency in the messages sent to others.

REVIEW Therapeutic Communication

RELATE Link the Concepts and Exemplars

Linking the exemplar of therapeutic communication with the concept of advocacy:

1. How do strong therapeutic communication skills contribute to the nurse's role as a patient advocate?
2. How do strong therapeutic communication skills contribute to the nurse's ability to work within groups to advocate for patients?

Linking the exemplar of therapeutic communication with the concept of teaching and learning:

3. The nurse is preparing to teach a patient who is newly diagnosed with diabetes about self-care. Describe the four phases of the therapeutic relationship as it applies to the patient-teaching plan.

4. While teaching the patient with diabetes, the nurse accidentally creates a barrier to the therapeutic relationship by misspeaking. What should the nurse do next?

REFLECT Apply Your Knowledge

Zainah Kattan is a newly licensed nurse working at the Neighborhood Hospital. She is assigned the care of Lydia Ocampo, a 70-year-old woman who was born and raised in the Philippines, who has been diagnosed with Alzheimer disease. Ms. Ocampo was admitted with a fractured hip following a fall at home that occurred when she was wandering around her house late one

night. Ms. Ocampo was assigned a different nurse yesterday, but Danilo Ocampo, her husband, complained to the nurse manager when he came to visit and found

her restrained and yelling for help with an untouched breakfast tray in front of her. Mr. Ocampo requested that a different nurse be assigned to his wife's care from now on. Ms. Kattan is happy

to act as her primary nurse. She develops rapport with Mr. Ocampo and gets satisfaction from caring for his wife by helping her to feel more comfortable.

1. When communicating with a patient diagnosed with later-stage Alzheimer disease, what strategies will the nurse employ?
2. Why does the development of rapport with Mr. Ocampo improve the patient's ability to meet expected outcomes?
3. Mr. Ocampo complains to Ms. Kattan about the poor care provided to his wife by the other nurse, Bobby Schofield. How should Ms. Kattan respond to this statement?

Overview

Effective communication among healthcare professionals is vital to the quality of patient care. Generally, healthcare personnel communicate through discussion, reports, and records. A **discussion** is an informal oral consideration of a subject by two or more healthcare personnel to identify a problem or establish strategies to resolve a problem. A **report** is oral, written, or electronic communication intended to convey information to others. For instance, nurses always report on patients at the end of a hospital work shift. A **record** may be handwritten or electronic. The process of making an entry on a patient record is called **recording**, **charting**, or **documenting**.

A clinical record, also called a **chart** or **patient record**, is a formal, legal document that provides evidence of a patient's care. Although healthcare organizations use different systems and forms for documentation, all patient records include similar information.

Each healthcare organization has policies about recording and reporting patient data, and each nurse is accountable for

following the organization's standards. Agencies also indicate which nursing assessments and interventions can be recorded by RNs and which can be charted by unlicensed personnel. In addition, The Joint Commission requires patient record documentation to be timely, complete, accurate, confidential, and specific to the patient.

The need for documentation to be specific to the patient goes beyond simply ensuring that the individual patient's information is entered correctly in the healthcare record. Complete, accurate, and specific patient information includes entering relevant, objective information about cultural and other considerations that will help other members of the healthcare team who work with the patient to provide culturally appropriate, respectful care.

Ethical and Legal Considerations

The American Nurses Association (ANA) Code of Ethics (2015) states, "[T]he nurse has a duty to maintain confidentiality of all patient information" (p. 9). The patient's record is legally protected as a private record of the patient's care.

Access to the patient's record is restricted to healthcare professionals involved in giving care to that patient. The institution or agency is the rightful owner of the patient's record. This does not, however, exclude the patient's rights to the same records. See the module on Ethics and the module on Legal Issues for more information.

On April 14, 2003, changes were made to the Health Insurance Portability and Accountability Act (HIPAA) regulations to maintain the privacy and confidentiality of protected health information (PHI). PHI is identifiable health information that is transmitted or maintained in any form or medium, including verbal discussions, electronic communications with or about patients, and written communications.

For purposes of education and research, most agencies allow student and graduate healthcare professionals access to patient records. The records are used in patient conferences, clinics, rounds, patient studies, and written papers. The student or graduate is bound by a strict ethical code and legal responsibility to hold all information in confidence. Both students and practicing nurses have the responsibility to protect the patient's privacy by not using a name or any statements that may identify the patient in their worksheets, notes for class, or any notations they make that could potentially leave the facility's premises. Most facilities provide shredders or other receptacles for discarding material that contains PHI.

Ensuring Confidentiality of Electronic Records

Because of the increased use of computerized patient records, healthcare agencies have developed policies and procedures to ensure the privacy and confidentiality of patient information stored electronically. In addition, the Security Rule of HIPAA governs the security of electronic forms of protected health information and defines sanctions and fines for hospitals, clinics, and providers who violate this security. Some suggestions for ensuring the confidentiality and security of electronic records include:

1. A personal password is required to enter and sign off computer files. Do not share this password with anyone, including other healthcare team members, and do not display passwords in the computer area. Use only agency computers that have security functions built into the system for transmission of PHI.
2. After logging on, never leave a computer terminal unattended. Sign out of the computer before leaving it unattended to prevent unintended access to patient information.
3. Do not leave patient PHI displayed on the monitor where others may see it.
4. Shred all unneeded computer-generated worksheets.
5. Know the facility's policy and procedure for correcting an entry error.
6. Follow agency procedures for documenting sensitive material, such as a diagnosis of a sexually transmitted infection.
7. Information technology personnel must install a fire-wall to protect the server from unauthorized access.

Purposes of Patient Records

Patient records are kept for a number of purposes:

- **Communication.** The patient record serves as the vehicle by which different healthcare professionals who interact with a patient communicate with each other. This prevents fragmentation, repetition, and delays in patient care.
- **Planning patient care.** Each healthcare professional uses data from the patient's record to plan care for that patient. A primary care provider, for example, may order a specific antibiotic after establishing that the patient's temperature is steadily rising and that laboratory tests reveal the presence of a certain microorganism. The nurse uses baseline and ongoing data to evaluate the effectiveness of the nursing care plan.
- **Auditing health agencies.** An audit is a review of patient records for quality assurance purposes (see the module on Quality Improvement). Accrediting agencies such as The Joint Commission may review patient records to determine whether a particular health agency is meeting required standards.
- **Research.** The information contained in a record can be a valuable source of data for research. The treatment plans for a number of patients with the same health problems can yield information helpful in treating other patients.
- **Education.** Students in health disciplines often use patient records as educational tools. A record can frequently provide a comprehensive view of the patient, the illness, effective treatment strategies, and factors that affect the outcome of the illness.
- **Reimbursement.** Documentation helps a facility receive reimbursement from the federal government. For a facility to obtain payment through Medicare, for example, the patient's clinical record must contain the correct diagnosis-related group (DRG) codes and reveal that the appropriate care has been given. Codable diagnoses, such as DRGs, are supported by accurate and thorough recordings of a patient's care by nurses. Accurate coding not only facilitates reimbursement from the federal government but also facilitates reimbursement from insurance companies and other third-party payers. If additional care, treatment, or length of stay becomes necessary for the patient's welfare, thorough documentation will help justify these needs.
- **Legal documentation.** The patient's record is a legal document and usually is admissible in court as evidence. In some jurisdictions, however, the record is considered inadmissible as evidence when the patient objects, because information the patient gives to the physician is confidential.
- **Healthcare analysis.** Information from records may assist healthcare planners to identify agency needs, such as overused and underused hospital services. Records can be used to establish the costs of various services and to identify those services that cost the agency money and those that generate revenue.

Documentation Systems

A number of documentation systems are in current use. The most common are the source-oriented record; the problem-oriented medical record; the problems, interventions, evaluation (PIE) model; focus charting; charting by exception (CBE); and electronic documentation. In the American Recovery and Reinvestment Act (ARRA) of 2009, the federal government mandated that all healthcare facilities move to electronic medical records from paper records. Electronic records are the fastest growing type and are quickly replacing or augmenting the other methods of documentation.

Source-oriented Record

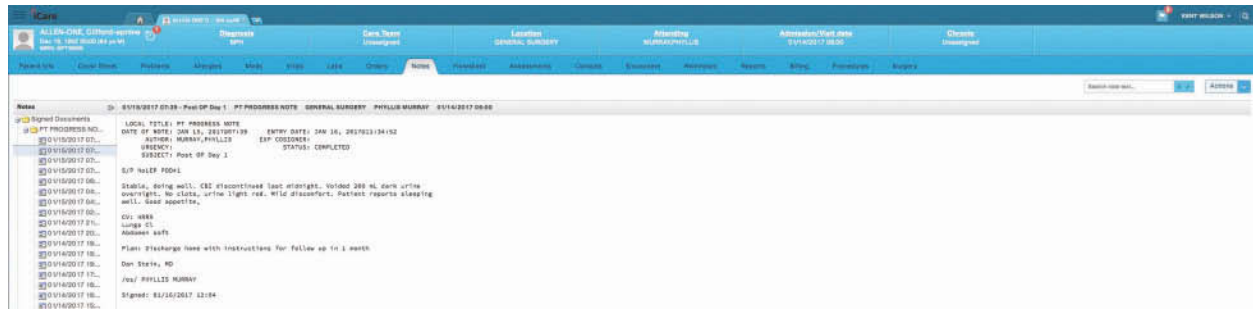

The traditional patient record is a **source-oriented record**. Each individual or department makes notations in a separate

section or sections of the patient's chart. For example, the admissions department has an admission sheet; the physician has a physician's order sheet, a physician's history sheet, and progress notes; nurses use the nurses' notes; and other departments or personnel have their own records. In this type of record, information about a particular problem is distributed throughout the record. For example, if a patient had left hemiplegia (paralysis of the left side of the body), data about this problem might be found in the physician's history sheet, on the physician's order sheet, in the nurses' notes, in the physical therapist's record, and in the social service record. **Table 38-7** » lists the components of a source-oriented record.

Source-oriented records may be compiled by narrative charting. **Narrative charting** consists of written notes that include routine care, normal findings, and patient problems

TABLE 38-7 Components of the Source-oriented Record

Form	Information
Admission (face) sheet	<ul style="list-style-type: none"> Legal name, birth date, age, gender Identification number Address Marital status; closest relatives or individual to notify in case of emergency Date, time, and admitting diagnosis Food or drug allergies Name of admitting (attending) physician Insurance information Any assigned DRGs
Initial nursing assessment	<ul style="list-style-type: none"> Findings from the initial nursing history and physical health assessment
Graphic record	<ul style="list-style-type: none"> Body temperature Pulse rate Respiratory rate Blood pressure Daily weight Special measurements such as fluid intake and output and oxygen saturation
Daily care record	<ul style="list-style-type: none"> Activity Diet Bathing Elimination records
Special flow sheets	<ul style="list-style-type: none"> Examples: fluid balance record, skin assessment
Medication record	<ul style="list-style-type: none"> Name, dosage, route, time, date of regularly administered medications Name or initials of individual administering the medication
Nurses' notes	<ul style="list-style-type: none"> Pertinent assessment of patient Specific nursing care, including teaching and patient's responses Patient's complaints and how patient is coping
Medical history and physical examination	<ul style="list-style-type: none"> Past and family medical history Present medical problems Differential or current diagnoses Findings of physical examination by the primary care provider
Physician's order sheet	<ul style="list-style-type: none"> Medical prescriptions for medications, treatments, and so on
Physician's progress notes	<ul style="list-style-type: none"> Medical observations, treatments, patient progress, and so on
Consultation records	<ul style="list-style-type: none"> Reports by medical and clinical specialists
Diagnostic reports	<ul style="list-style-type: none"> Examples: laboratory reports, x-ray reports, CT scan reports
Consultation reports	<ul style="list-style-type: none"> Examples: physical therapy, respiratory therapy
Patient discharge plan and referral summary	<ul style="list-style-type: none"> Started on admission and completed on discharge Includes nursing problems, general information, and referral data

Figure 38-10 » A narrative note in an electronic health record (EHR).

(Figure 38-10 »). There is no right or wrong order to the information, although chronologic order is frequently used. Although narrative charting is a traditional part of the source-oriented record, few institutions today use only narrative charting. It is being replaced by systems such as charting by exception and focus charting (discussed below). Many agencies combine narrative charting with another system. For example, an agency using a charting-by-exception system may use narrative charting only when describing abnormal findings. However, narrative charting is expedient in emergency situations. When using narrative charting, nurses must ensure the information is organized in a clear, coherent manner. Using the nursing process as a framework is one way to do this.

Source-oriented records are convenient because (a) care providers from each discipline can easily locate the forms on which to record data and (b) it is easy to trace the information specific to one's discipline. The disadvantage is that information about a particular patient problem is scattered throughout the chart, making it difficult to find chronologic information on a patient's problems and progress. This can lead to decreased communication among the healthcare team, an incomplete picture of the patient's care, and a lack of coordination of care (International Federation of Health Information Management Associations [IFHIMA], 2014).

Problem-oriented Medical Record

The **problem-oriented medical record (POMR)**, or **problem-oriented record (POR)**, was established by Lawrence Weed in the 1960s. In a POMR, data are arranged according to the problems the patient has rather than according to the source of the information. Members of the healthcare team contribute to the problem list, plan of care, and progress notes. Plans for each active or potential problem are created, and progress notes are recorded for each problem.

The advantages of POMRs are that they encourage collaboration, and that the problem list in the front of the chart alerts caregivers to the patient's needs, making it easier to track the status of each problem. The disadvantages of a POMR are that caregivers differ in their ability to use the required charting format, constant vigilance is required to maintain an up-to-date problem list, and it is somewhat inefficient because assessments and interventions that apply to more than one problem must be repeated.

The POMR has four basic components: database, problem list, plan of care, and progress notes. In addition, flow sheets and discharge notes are added to the record as needed.

Database

The database of a POMR consists of all information known about the patient when the patient first enters the healthcare agency. It includes the nursing assessment, the physician's history, social and family data, and the results of the physical examination and baseline diagnostic tests. Data are constantly updated as the patient's health status changes.

Problem List

The problem list is derived from the database. It is usually kept at the front of the chart and serves as an index to the numbered entries in the progress notes. Problems are listed in the order in which they are identified, and the list is continually updated as new problems are identified and others resolved. All caregivers may contribute to the problem list, which includes the patient's physiologic, psychologic, social, cultural, spiritual, developmental, and environmental needs. Primary care providers write problems as medical diagnoses, surgical procedures, or symptoms; nurses write problems as nursing diagnoses.

As the patient's condition changes or more data are obtained, problems may need to be redefined. When a problem is resolved, a line is drawn through it and the number is not used again for that patient.

Plan of Care

In the POMR method, the initial list of orders or plan of care is made with reference to the active problems. Care plans are generated by the individual who lists the problems. Physicians write physician's orders or medical care plans; nurses write nursing orders or nursing care plans. The written plan in the record is listed under each problem in the progress notes and is not isolated as a separate list of orders.

Progress Notes

A progress note in the POMR is a chart entry made by any of the healthcare professionals who are involved in a patient's care, who all use the same type of sheet for notes. Progress notes are numbered to correspond to the problems on the problem list and may be lettered for the type of data. The SOAP format is frequently used. **SOAP** is an acronym for subjective data, objective data, assessment, and planning.

Over the years, the SOAP format has been modified; the acronyms **SOAPIE** and **SOAPIER** refer to formats that add interventions, evaluation, and revision.

Subjective data consist of information obtained from what the patient says.

Objective data consist of information that is measured or observed by use of the senses (e.g., vital signs, laboratory and x-ray results).

Assessment is the interpretation or conclusions drawn about the subjective and objective data.

Plan of care is designed to resolve the stated problem. The initial plan is written by the individual who enters the problem into the record. All subsequent plans, including revisions, are entered into the progress notes.

Interventions refer to the specific interventions that have actually been performed by the caregiver.

Evaluation includes patient responses to nursing interventions and medical treatments. This is primarily reassessment data.

Revision reflects care plan modifications suggested by the evaluation. Changes may be made in desired outcomes, interventions, or target dates.

An example of a nursing progress note using SOAPIER is shown in **Figure 38–11** ».

PIE Model

The **PIE documentation model** groups information into three categories. **PIE** is an acronym for

- P**roblems,
- I**nterventions
- E**valuation of nursing care.

This system consists of a patient care assessment flow sheet and progress notes. The **flow sheet** uses specific assessment criteria in a particular format, such as human needs or functional health patterns. The time parameters for a flow sheet can vary from minutes to months. In a hospital intensive care unit, for example, a patient's blood pressure may be

monitored by the minute, whereas in an ambulatory clinic a patient's blood glucose level may be recorded once a month.

After the assessment, the nurse establishes and records specific problems on the progress notes, often using NANDA-I diagnoses to word the problem. If there is no approved nursing diagnosis for a problem, the nurse develops a problem statement using NANDA-I's three-part format: patient's response, contributing or probable causes of the response, and characteristics manifested by the patient. The *problem statement* is labeled "P" and is referred to by number (e.g., P #5). The *interventions* employed to manage the problem are labeled "I" and are numbered according to the problem (e.g., I #5). The *evaluation* of the effectiveness of the interventions is labeled "E" and is numbered according to the problem (e.g., E #5).

The PIE system eliminates the traditional care plan and incorporates an ongoing care plan into the progress notes. Therefore, the nurse does not have to create and update a separate plan. One of the disadvantages to PIE is that the nurse must review all nursing notes before giving care to determine which problems are current and which interventions were effective.

Focus Charting

Focus charting is intended to make the patient and the patient's concerns and strengths the focus of care. Three columns for recording are usually used: date and time, focus, and progress notes. The *focus* may be a condition, nursing diagnosis, behavior, sign or symptom, acute change in the patient's condition, or patient strength. The progress notes are organized into (D) data, (A) action, and (R) response, referred to as DAR. The *data* category reflects the assessment phase of the nursing process and consists of observations of patient status and behaviors, including data from flow sheets (e.g., vital signs, pupil reactivity). The nurse records both subjective and objective data in this section.

The *action* category reflects planning and implementation and includes immediate and future nursing actions. It may also include any changes to the plan of care. The *response* category reflects the evaluation phase of the nursing process

The screenshot shows an EHR interface with a navigation bar at the top. The main content area displays a nursing progress note for a patient named 'Mr. Singh'. The note is dated 02/22/2017 and is categorized under 'GENERAL NOTE' and 'CARDIOLOGY'. The note content includes a history of a heart attack, current symptoms, and a plan of care.

History: Mr. Singh is a 68 y/o man seen on 02/22/2017 for follow-up 4 weeks after undergoing cardiac bypass surgery. He reports of chest pain despite previous angina. He experienced distal "stabbing" chest discomfort at the site of the surgical incision on his chest wall. He describes no PND or orthopnea. He reports no pain or edema to his calves when walking.

Physical Exam: Patient checks his blood pressure daily. Values are usually 120-140/80-90. He also effects from medications.

History of Present Illness: Patient's past history is significant for CAD, MI in 2012 and hypercholesterolemia. He also has hypertension. Note includes laboratory 20 mg daily, atorvastatin 40 mg daily, and ASA 325 mg daily.

Review of Systems: Patient is an elderly male, appearing younger than his stated age. Hx of angina, MI, and CAD. Height 5'10", weight 180 lbs, BMI 28.7.

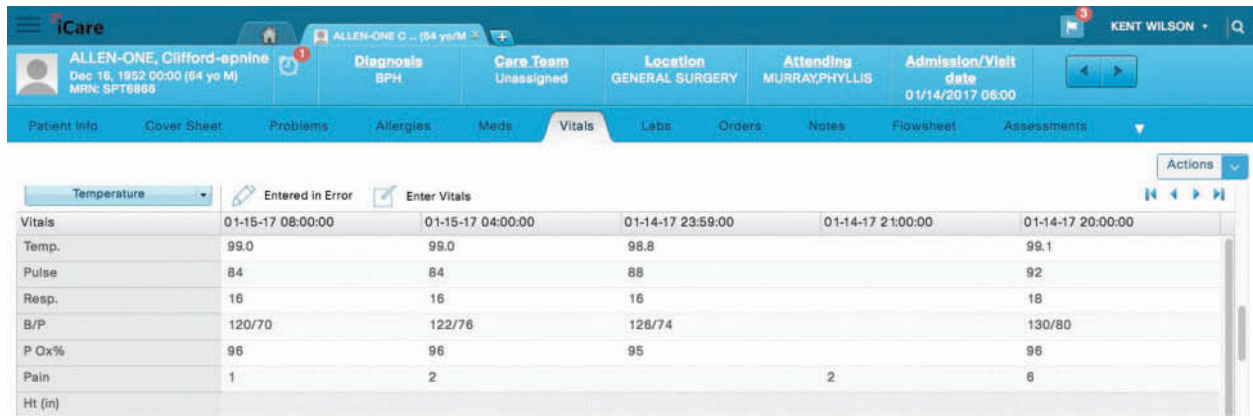

Cardiovascular: Chest wall: healing sternal scar without erythema or discharge. CV exam: No JVD and S4, no murmurs. Extremities: Incision from vein harvest on R medial calf is healing without erythema or discharge. Pedal pulses: Bilateral pedal pulses are 2+ bilaterally. No edema.

Assessment: A1: Seen for follow-up after surgery. 1. Coronary artery disease, 10 w/o signs/symptoms. Being well without angina or shortness of breath. Good exercise tolerance. 2. Hypertension, well controlled on atorvastatin, since he has been on 40mg.

Plan: A1: CAD - Continue with current med. - Report vital signs to be done today. - Follow-up appt in 3 mos. Hx: Hx - Check electrolytes today. - Encourage patient to monitor blood pressure.

Figure 38-12 » A sample vital signs graphic record in an EHR.

and describes the patient's response to any nursing and medical care.

The focus charting system provides a holistic perspective of the patient and the patient's needs. It also provides a nursing process framework for the progress notes (DAR). The three components do not need to be recorded in order, and each note does not need to have all three categories. Flow sheets and checklists are frequently used on the patient's chart to record routine nursing tasks and assessment data.

Charting by Exception

Charting by exception (CBE) is a documentation system in which only abnormal or significant findings or exceptions to norms are recorded. CBE incorporates three key elements (Guido, 2013):

1. **Flow sheets.** Examples of flow sheets include a graphic record (**Figure 38-12** »), fluid balance record, daily nursing assessments record (**Figure 38-13** »), patient teaching record, patient discharge record, and skin assessment record.
2. **Standards of nursing care.** Documentation by reference to the agency's printed standards of nursing practice eliminates much of the repetitive charting of routine care. An agency using CBE must develop its own specific standards of nursing practice that identify the minimum criteria for patient care regardless of clinical area. Some units may also have unit-specific standards unique to the type of patient. For example, "The nurse must ensure that the unconscious patient has oral care at least every 4 hours." Documentation of care according to these specified standards involves only a check mark in the routine standards box on the graphic record. If not all of the standards are implemented, an asterisk on the flow sheet is made with reference to the nurses' notes. All exceptions to the standards are fully described in narrative form on the nurses' notes.
3. **Bedside access to chart forms.** In the CBE system, all flow sheets are kept at the patient's bedside to allow

immediate recording and to eliminate the need to transcribe data from the nurse's worksheet to the permanent record.

The advantages to this system are the elimination of lengthy, repetitive notes and that it makes changes in the patient's condition more obvious. Inherent in CBE is the presumption that the nurse did assess the patient and determined what responses were normal and abnormal. Many nurses believe in the saying "not charted, not done" and subsequently may feel uncomfortable with the CBE documentation system. One suggestion is to write N/A on flow sheets where the items are not applicable and to not leave blank spaces. This would then avoid the possible misinterpretation that the assessment or intervention was not completed by the nurse.

Electronic Documentation

Computerized clinical record systems are the fastest growing sector in the field of documentation. Electronic health record (EHR) or electronic medical record (EMR) systems provide an efficient way to manage the huge volume of information required in contemporary healthcare. Nurses use computer databases to store the patient data, add new data, create and revise care plans, and document patient progress. Some institutions provide a computer terminal at each patient's bedside, such as a Computer on Wheels (COW) or a small handheld device for the nurse to carry; these technologies enable the nurse to document care immediately after providing it.

Computers and related electronic devices make care planning and documentation relatively easy. To record nursing actions and patient responses, the nurse either chooses from standardized lists of terms or types narrative information into the device. Automated speech-recognition technology allows nurses to enter data by voice for conversion to written documentation. However, according to HIPAA, if the spoken word is used to create or address protected health information, the nurse must be alert and aware of others who might hear the dictation and take care to protect the privacy of the patient's information. Figure 38-13 » Sample of a portion of a daily nursing CBE assessment form in an EHR.

healthcare is that of the “medical scribe,” who is a paraprofessional trained to enter physician assessment data and medical orders directly into the EMR on behalf of the provider and accordingly free the physician to focus more attention on the patient than the computer.

EHRs make it possible to transmit information from one care setting to another. The nursing Minimum Data Set (MDS) is an effort to establish standards for collecting standardized, essential nursing data for inclusion in computer databases.

EMRs contain the standard medical and clinical data gathered in one provider’s office. EHRs go beyond data col-

lected at the individual healthcare provider’s office and over time compile a comprehensive patient history (Office of the National Coordinator for Health Information Technology, 2014). EHR data can be created, managed, and consulted by healthcare staff within the same agency as well as across any number of healthcare organizations. EMRs and EHRs are more useful than paper records by most measures. In particular, electronic records can track data over time, identify patients who are due for particular procedures, monitor patients’ vaccination schedules, and improve patient safety.

Documentation systems called electronic medication administration records (eMARs) are specifically used to

keep track of patient medication information (Techopedia, 2016). eMARs use barcodes and a handheld scanner to send and fill prescriptions. Medication dosages, number of refills, types of medications, medication classifications, refill history, prescription status, and tracking information are all included in the eMAR. These records accelerate the prescribing process, and their quality assurance tools and audit tracking features enhance available information and severely limit the possibility of a medication error.

Case Management

The case management model emphasizes high-quality, cost-effective care delivered within an established length of stay. This model uses an interprofessional approach to planning and documenting patient care using *critical pathways*. These forms identify the outcomes that certain groups of patients are expected to achieve on each day of care, along with the interventions necessary for each day. **Figure 38-14** » illustrates part of a critical pathway for a patient with a total hip replacement.

Along with critical pathways, the case management model incorporates graphics and flow sheets. Progress notes typically use some type of charting by exception. For example, if goals are met, no further charting is required. A goal that is not met is called a **variance**. A variance is a deviation from what is planned on the critical pathway, that is, an unexpected occurrence that affects the planned care or the patient's responses to care. When a variance occurs, the nurse writes a note documenting the unexpected event, the cause, and actions taken to correct the situation or justify the actions taken.

The case management model promotes collaboration and teamwork among caregivers, helps to decrease length of

stay, and makes efficient use of time. Because care is goal focused, the quality of care may improve. However, critical pathways work best for patients with one or two diagnoses and few individualized needs. Patients with multiple diagnoses (e.g., a patient with a hip fracture, pneumonia, diabetes, and pressure sore) or those with an unpredictable course of symptoms (e.g., a patient with seizures) are difficult to document on a critical path.

Documenting Nursing Activities

The patient record should describe the patient's ongoing status and reflect the full range of the nursing process. Regardless of the records system used in an agency, nurses document evidence of the nursing process on a variety of forms throughout the clinical record (**Table 38-8** »).

Admission Nursing Assessment

A comprehensive admission assessment, also referred to as an initial database, nursing history, or nursing assessment, is completed when the patient is admitted to the nursing unit. These forms can be organized according to health patterns, body systems, functional abilities, health problems and risks, nursing model, or type of healthcare setting (e.g., labor and delivery, pediatrics, mental health). The nurse generally records ongoing assessments or reassessments on flow sheets or on nursing progress notes.

Nursing Care Plans

The Joint Commission requires that the clinical record include evidence of patient assessments, nursing diagnoses and/or patient needs, nursing interventions, patient outcomes, and evidence of a current nursing care plan. Depending on the records system being used, the nursing care plan may be separate from the patient's chart, recorded in progress notes and other forms in the patient record, or incorporated into an interprofessional plan of care. See the module on Clinical Decision Making for information on types of nursing care plans and strategies for their development and use.

Flow Sheets

A flow sheet enables the nurse to record nursing data quickly and concisely and provides an easy-to-read record of the patient's condition over time.

CRITICAL PATHWAY: TOTAL HIP REPLACEMENT		
	DOS/Day 1	Days 2-3
Pain Management	Outcome: • Verbalizes comfort or tolerance of pain Circle: V NV Variance:	Outcome: • Verbalizes comfort with pain control measures Circle: V NV Variance:
Respiratory	Outcomes: • Breath sounds clear to auscultation • Achieves 50% of volume goal on incentive spirometer Circle: V NV Variance:	Outcomes: • Breath sounds clear to auscultation • Achieves 100% of volume goal on incentive spirometer Circle: V NV Variance:
Key: V = Variance NV = No Variance

Figure 38-14 » Excerpt from a critical pathway documentation form.

TABLE 38-8 Documentation for the Nursing Process

Step	Documentation Forms
Assessment	Initial assessment form, various flow sheets
Nursing diagnosis	Nursing care plan, critical pathway, progress notes, problem list
Planning	Nursing care plan, critical pathway
Implementation	Progress notes, flow sheets
Evaluation	Progress notes

Note: All steps are recorded on discharge/referral summaries.

- **Graphic record.** This record typically indicates body temperature, pulse, respiratory rate, blood pressure, weight, and, in some agencies, other significant clinical data such as admission or postoperative day, bowel movements, appetite, and activity.
- **Intake and output (I&O) record.** All routes of fluid intake and all routes of fluid loss or output are measured and recorded on this form. Frequently this I&O form permits the recording of a daily weight and percentage of meal consumption.
- **Medication administration record.** Medication flow sheets usually include designated areas for the date of the medication order, the expiration date, the medication name and dose, the frequency of administration and route, and the nurse's signature. Some records also include a place to document the patient's allergies.
- **Skin assessment record.** A skin or wound assessment is often recorded on a flow sheet. These records may include categories related to stage of skin injury, drainage, odor, culture information, and treatments.

Progress Notes

Progress notes made by nurses provide information about the progress a patient is making toward desired outcomes. Therefore, in addition to assessment and reassessment data, progress notes include information about patient problems and nursing interventions and evaluation of these interventions. The format used depends on the documentation system in place in the institution.

Nursing Discharge/Referral Summaries

A discharge note and referral summary are completed when the patient is being discharged and transferred to another institution or to a home setting where a visit by a community health nurse is required. Many institutions provide forms for these summaries. Some records combine the discharge plan, including instructions for care, and the final progress note. Many are designed with checklists to facilitate data recording.

If the discharge plan is given directly to the patient and family, it is imperative that instructions be written in terms that can be readily understood. For example, medications, treatments, and activities should be written in layman's terms, and use of medical abbreviations (such as *tid*) should be avoided.

If a patient is transferred within the facility or from a long-term facility to a hospital, a report needs to accompany the patient to ensure continuity of care in the new area. It should include all components of the discharge instructions but also describe the condition of the patient prior to transfer. Any teaching or patient instruction that has been done should also be described and recorded.

If the patient is being transferred to another institution or to a home setting where a visit by a home health nurse is required, the discharge note takes the form of a referral summary. Regardless of format, discharge and referral summaries usually include some or all of the following:

- Description of patient's physical, mental, and emotional status at discharge or transfer
- Resolved health problems

- Unresolved continuing health problems and continuing care needs; may include a review-of-systems checklist that considers integumentary, respiratory, cardiovascular, neurologic, musculoskeletal, gastrointestinal, elimination, and reproductive problems
- Treatments that are to be continued (e.g., wound care, oxygen therapy)
- Current medications
- Restrictions that relate to (a) activity such as lifting, stair climbing, walking, driving, work; (b) diet; and (c) bathing, such as sponge bath, tub, or shower
- Functional/self-care abilities in terms of vision, hearing, speech, mobility with or without aids, meal preparation and eating, preparation and administration of medications, and so on
- Comfort level
- Support networks, including family, significant others, religious adviser, community self-help groups, home care and other community agencies available, and so on
- Patient education provided in relation to disease process, activities and exercise, special diet, medications, specialized care or treatments, follow-up appointments, and so on
- Discharge destination (e.g., home, nursing home) and mode of discharge (e.g., walking, wheelchair, ambulance)
- Referral services (e.g., social worker, home health nurse).

Facility-specific Documentation

Documentation systems and requirements vary by facility. The documentation required in an acute care setting, as discussed in the early part of this exemplar, is different from the documentation required by long-term care, home care, or other care delivery sites such as outpatient clinics.

Long-term Care Documentation

Long-term facilities usually provide two types of care: skilled or intermediate. Patients needing skilled care require more extensive nursing care and specialized nursing skills. In contrast, an intermediate-care focus is appropriate for patients who usually have chronic illnesses and may only need assistance with activities of daily living (such as bathing and dressing).

Requirements for documentation systems in long-term care settings are based on professional standards, federal and state regulations, and the policies of the healthcare agency. Laws influencing the kind and frequency of documentation required are found through the Health Care Financing Administration (HCFA), a branch of the U.S. Department of Health and Human Services, and the Omnibus Budget Reconciliation Act (OBRA) of 1987. The OBRA law, for example, requires that (a) a comprehensive assessment (the Minimum Data Set [MDS] for Resident Assessment and Care Screening) be performed within 4 days of a patient's admission to a long-term care facility, (b) a formulated plan of care must be completed within 7 days of admission, and (c) the assessment and care screening process must be reviewed every 3 months. Documentation must also comply with requirements set by Medicare and Medicaid. These

requirements vary with the level of service provided and other factors. For example, Medicare provides little reimbursement for services provided in long-term care facilities except for services that require skilled care such as chemotherapy, tube feedings, and ventilators. For these patients, the nurse must provide daily documentation to verify the need for service and reimbursement.

Nurses need to familiarize themselves with regulations influencing the kind and frequency of documentation required in long-term care facilities. Usually the nurse completes a nursing care *summary* at least once a week for patients requiring skilled care and every 2 weeks for patients who require intermediate care. Summaries should address specific problems noted in the care plan; mental status; ADLs; hydration and nutrition status; safety measures needed; medications and other treatments; preventive measures; and any behavior modifications or assistive devices needed.

Home Care Documentation

In 1985, the HCFA mandated that home health agencies standardize their documentation methods to meet requirements for Medicare and Medicaid and other third-party disbursements. Two records are required: (1) a home health certification and plan of treatment form and (2) a medical update and patient information form. The nurse assigned to the home care patient usually completes the forms, which must be signed by both the nurse and the attending physician. Information in a home care medical record often includes reports to third-party payers, a list of medications, an interprofessional plan of care, referral and intake forms, and patient assessments.

Parts of the medical record remain in the patient's home, whereas other parts are transferred to the office (Potter et al., 2013). Duplication of medical records or use of a continuous EMR is necessary for the relevant information to be available in all necessary locations. Some home health agencies provide nurses with laptop computers, tablets, or smartphones to make records available in multiple locations. This allows the nurse to add new patient information to records at the agency without traveling to the office. Electronic records enable the entire healthcare team to have the information necessary to provide consistent and safe care.

General Guidelines for Recording

Because a patient's medical record is a legal document and may be used to provide evidence in court, many factors are considered in recording. Healthcare personnel must not only maintain the confidentiality of the patient's record but also meet legal standards in the process of recording.

Date and Time

Document the date and time of each recording. This is essential not only for legal reasons but also for patient safety. Record the time in the conventional manner (e.g., 9:00 a.m. or 3:15 p.m.) or according to the 24-hour clock (military clock), which avoids confusion about whether a time was a.m. or p.m.

Timing

Follow the agency's policy about the frequency of documenting, but adjust the frequency as a patient's condition

indicates; for example, a patient whose blood pressure is changing requires more frequent documentation than a patient whose blood pressure is stable. As a rule, documenting should be done as soon as possible after an assessment or intervention. No recording should be done *before* providing nursing care.

Accepted Terminology

Use only commonly accepted abbreviations, symbols, and terms as specified by the agency. Many abbreviations are standard and used universally; others are used only in certain geographic areas. Many healthcare facilities supply an approved list of abbreviations and symbols to prevent confusion. A large number of healthcare facilities are now moving away from the use of any abbreviations. When in doubt about whether to use an abbreviation, write the term in full until certain about the abbreviation. **Table 38-9** » lists some common abbreviations used in healthcare.

In 2004, The Joint Commission developed National Patient Safety Goals to reduce communication errors. These goals are required to be implemented by all organizations accredited by The Joint Commission. As a result, accredited organizations must develop a "Do Not Use" list of abbreviations, acronyms, and symbols. These lists must include those banned by The Joint Commission.

» **Stay Current:** Keep up with The Joint Commission's "Do Not Use" list by visiting its website at http://www.jointcommission.org/facts_about_do_not_use_list/.

Correct Spelling

Correct spelling is essential for accuracy in recording. If unsure how to spell a word, the nurse should look it up. Two decidedly different medications may have similar spellings with serious patient safety considerations, such as Fosamax and Flomax.

Signature

Each recording on the nursing notes is signed by the nurse documenting it. The signature includes the name and title, for example, "Susan J. Green, RN" or "S. J. Green, RN." With computerized charting, each nurse has her own code, which allows the person who entered the documentation to be identified.

The following title abbreviations are often used, but nurses need to follow agency policy about how to sign their names:

RN	registered nurse
LVN	licensed vocational nurse
LPN	licensed practical nurse
NA	nursing assistant
CNA	certified nursing assistant
MA	medical assistant
NS	nursing student
PCA	patient care associate
PCNA	patient care nursing assistant
SN	student nurse
NP	nurse practitioner
APRN	advanced practice registered nurse

TABLE 38–9 Commonly Used Abbreviations

Abbreviation	Term	Abbreviation	Term
Abd	Abdomen	meds	Medications
ABO	The main blood group system	mL, ml	Milliliter
ac	Before meals	mod	Moderate
ad lib	As desired	neg	Negative
ADL	Activities of daily living	Ø	None
Adm	Admitted or admission	#	Number or pounds
a.m.	Morning	NPO, NBM	Nothing by mouth
amb	Ambulatory	NS, N/S	Normal saline
amt	Amount	OD	Right eye or overdose
approx	Approximately	OOB	Out of bed
bid, BID	Twice daily	OS	Left eye
bm, BM	Bowel movement	pc	After meals
BP	Blood pressure	PE, PX	Physical examination
BRP	Bathroom privileges	per	By or through
ċ	With	p.m.	Afternoon
C	Celsius (centigrade)	po	By mouth
CBC	Complete blood count	postop	Postoperatively
c/o	Complains of	preop	Preoperatively
DAT	Diet as tolerated	prep	Preparation
drsg	Dressing	prn, PRN	When necessary
Dx	Diagnosis	qid, QID	Four times a day
ECG	Electrocardiogram	(R)	Right
F	Fahrenheit	ſ	Without
fld	Fluid	stat	At once, immediately
GI	Gastrointestinal	tid, TID	Three times a day
gtt	Drop	TO	Telephone order
h, hr	Hour	TPR	Temperature, pulse, respirations
H ₂ O	Water	VO	Verbal order
I&O	Intake and output	VS	Vital signs
IV	Intravenous	WNL	Within normal limits
(L)	Left	wt	Weight
LMP	Last menstrual period		

*Institutions may elect to include some of these abbreviations on their "Do Not Use" list. Check the agency's policy.

Accuracy

Before making an entry, the nurse should ensure they are in the correct chart or electronic record. Notations on records must be accurate and correct. Accurate notations consist of facts or objective observations rather than opinions or interpretations. It is more accurate, for example, to write that the patient "refused medication" (fact) than to write that the patient "was uncooperative" (opinion or a judgment), or to record that a patient "was crying" (observation) rather than that the patient "was depressed" (interpretation). Similarly, when a patient expresses worry about a diagnosis or problem, this should be quoted directly on the record: "Stated: 'I'm worried about my leg.'" When describing

something, avoid general words, such as *large*, *good*, or *normal*, which can be interpreted in different ways. For example, chart specific data such as "2 cm × 3 cm bruise" rather than "large bruise."

Follow agency policies regarding documenting errors and recording the correct information. The original entry must remain visible.

Sequence

Document events in the order in which they occur; for example, record assessments, then the nursing interventions, and then the patient's responses. Update as needed or according to agency protocols.

Box 38–6

Dos and Don'ts of Documentation

DO

- Chart a change in a patient's condition **and** show that follow-up actions were taken.
- Read the nurses' notes prior to care to determine whether there has been a change in the patient's condition.
- Be timely. A late entry is better than no entry; however, the longer the period of time between actual care and charting, the greater the risk for recording inaccurate information or omitting necessary information.
- Use objective, specific, and factual descriptions.
- Correct charting errors in the manner specified by agency policy.
- Chart all teaching.
- Record the patient's actual words by putting quote marks around the words.

- Chart the patient's response to interventions.
- Review your notes. Are they clear? Do they reflect what you want to say?

DON'T

- Chart in advance of the event (e.g., procedure, medication).
- Use vague terms (e.g., "appears to be comfortable," "had a good night").
- Chart for someone else.
- Use "patient" instead of the patient's name.
- Alter a record even if requested by a superior or a physician.
- Record assumptions or words reflecting bias (e.g., "complainer," "disagreeable").

Appropriateness

Record only information that pertains to the patient's health problems and care. Any other personal information that the patient conveys is inappropriate for the record. Recording irrelevant information may be considered an invasion of the patient's privacy and/or libelous. For example, a patient's disclosure that she is recently divorced would *not* be recorded on her medical record unless it had a direct bearing on her health problem.

Completeness

Not all data that a nurse obtains about a patient can be recorded. However, the information that is recorded needs to be complete and helpful to the patient and healthcare professionals.

Nurses' notes need to reflect the nursing process. The nurse should record all assessments, dependent and independent nursing interventions, patient problems, patient comments and responses to interventions and tests, progress toward goals, and communication with other members of the health team.

SAFETY ALERT Do not assume that the individual who is reading your charting will know that a common intervention (e.g., turning) has occurred because you believe it to be an "obvious" component of care.

Care that is *omitted* because of the patient's condition or refusal of treatment must also be recorded. Document what was omitted, why it was omitted, and who was notified.

Conciseness

Recordings need to be brief as well as complete to save time in communication. The patient's name and the word *patient* are omitted. For example, write, "Perspiring profusely. Respirations shallow, 28/min." End each thought or sentence with a period.

Legal Prudence

Accurate, complete documentation should give legal protection to the nurse, the patient's other caregivers, the health-care facility, and the patient. Admissible in court as a legal document, the clinical record provides proof of the quality of care given to a patient. Documentation is usually viewed by juries and attorneys as the best evidence of what really happened to the patient.

For the best legal protection, the nurse should not only adhere to professional standards of nursing care but also follow agency policy and procedures for intervention and documentation in all situations, especially high-risk situations (**Box 38–6** >>>).

REVIEW Documentation

RELATE Link the Concepts and Exemplars

Linking the exemplar of documentation with the concept of legal issues:

1. How does proper documentation reduce the risk of lawsuits?
2. What components of nursing care must be included in the nurse's documentation to meet legal requirements?

Linking the exemplar of documentation with the concept of quality improvement:

3. How is nursing documentation used to assess the quality of nursing care delivered?
4. How can incomplete documentation result in a negative evaluation of the quality of nursing care delivered?

REFLECT Apply Your Knowledge

Zainah Kattan is a 23-year-old nurse from a small, rural community. Zainah graduated from nursing school a few months ago and took a job working on a general medical–surgical inpatient unit at Neighborhood Hospital. Her goal is to eventually work in an adult intensive care unit. She recently received a sign-on bonus and looks forward to buying her first new car.

Zainah has a busy week because of increased patient loads. She has seven to eight patients of her own, and she has trouble managing her charting with all the patient care she has to do. She ends up staying up to

2 hours after each shift to get the charting done. Zainah's manager, Pat, talks with her about this and reviews the importance of point-of-care charting. The feedback he gives Zainah is generally positive.

1. Why is Zainah's manager trying to improve her point-of-care charting?
2. What are the potential drawbacks of waiting until the end of the shift to document care?
3. What strategies might you suggest to Zainah to help her improve point-of-care charting during a busy shift?

Exemplar 38.D Reporting

Exemplar Learning Outcomes**38.D Analyze reporting as it relates to communication.**

- Explain the purposes of reporting.
- Describe the handoff report.
- Outline the SBAR technique of communication.
- Describe the process of telephone communication.
- Summarize the care plan conference.

Overview

The purpose of **reporting** is to communicate specific information to an individual or group of individuals. A report, whether oral or written, should be concise, including pertinent information but no extraneous detail. In addition to change-of-shift reports and telephone reports, reporting can also include the sharing of information or ideas with colleagues and other health professionals about some aspect of a patient's care. Examples include the care plan conference and nursing rounds.

Note that the national CLAS standards (Office of Minority Health, 2013) have implications on reporting mechanisms in that agencies must consider culturally and linguistically appropriate services at all levels of communication throughout the agency. For example, consider a healthcare agency located in an urban area serving English-speaking, Spanish-speaking, and Arabic-speaking patients. As the agency employs more native Spanish and Arabic speakers to meet the needs of its patients, the agency must have policies and procedures in place to ensure that nurses and other healthcare providers who engage in reporting both in person (e.g., handoff reports) or through electronic means are able to communicate successfully with each other. Agencies must also ensure that communication and reporting mechanisms include opportunities for nurses and other providers to report pertinent cultural information about patients' healthcare and cultural needs.

Handoff Communication

Ineffective communication is the primary cause of sentinel events, which are serious, unexpected events (Popovich, 2016).

Exemplar Key Terms

Change-of-shift report, 2611
Handoff, 2610
Handoff communication, 2610
Reporting, 2610
SBAR, 2611
SHARE, 2610

As a result, hospitals are required to implement a standardized approach to “handing off” communication. **Handoff** is defined as “the transfer of information (along with authority and responsibility) during transitions in care across the continuum. It includes an opportunity to ask questions, clarify, and confirm” (Agency for Healthcare Research and Quality [AHRQ], 2014). Hospital handoffs occur at many times, including but not limited to when a patient is transferred between units, at the change of shift, and at discharge (AHRQ, 2015). The **hand-off communication** is a verbal or written exchange of information that encompasses the nursing care that has been provided along with all members of the healthcare team who have cared for the patient during the relevant time period (AHRQ, 2014).

The handoff process involves two groups, the senders and the receivers. The senders are the caregivers who are transmitting patient information and releasing care; the receivers are the caregivers who are accepting the patient and the patient's information.

The **SHARE** method can be used to accomplish a successful handoff:

- S**tandardize critical content.
- H**ardwire within your system.
- A**llow opportunity to ask questions.
- R**einforce quality and measurement.
- E**ducate and coach.

The Joint Commission (2012) provides several items that can be helpful in the handoff communication process. The goal of the new Hand-off Communications Targeted Solutions Tool (TST) is “to assist health care organizations

with the process of passing necessary and critical information about a patient from one caregiver to the next, or from one team of caregivers to another, to prevent miscommunication-related errors” (The Joint Commission, 2012).

» **Stay Current:** For more information regarding the handoff communication process, visit the following website: <https://www.aorn.org/guidelines/clinical-resources/tool-kits/patient-hand-off-tool-kit>.

Change-of-Shift Report

A **change-of-shift report** is a type of handoff communication given to all nurses on the next shift. Its purpose is to provide continuity of care for patients by providing the new caregivers with a quick summary of patient needs and details of care to be given.

Change-of-shift reports may be written or given orally, either in a face-to-face exchange or by audio recording. The face-to-face report permits the listener to ask questions during the report; written and audio-recorded reports are often briefer and less time consuming. Reports are sometimes given at the bedside, and patients as well as nurses may participate in the exchange of information. A thorough change-of-shift report:

- Follows a particular order (e.g., follow room numbers in a hospital).
- Provides basic identifying information for each patient (e.g., name, room number, bed designation).
- For new patients, provides the reason for admission or medical diagnosis (or diagnoses), surgery (date), diagnostic tests, and therapies in the past 24 hours.
- Includes significant changes in the patient’s condition and present information in order (i.e., assessment, nursing diagnoses, interventions, outcomes, and evaluation). For example, “Mr. Ronald Oakes said he had an aching pain in his left calf at 1400 hours. Inspection revealed no other signs. Calf pain is related to altered blood circulation. Rest and elevation of his legs on a footstool for 30 minutes provided relief.”
- Provides exact information, such as “Ms. Jessie Jones received morphine 6 mg IV at 1500 hours,” not “Ms. Jessie Jones received some morphine during the evening.”
- Reports patients’ need for special emotional support. For example, a patient who has just learned that his biopsy results revealed malignancy and who is now scheduled for a laryngectomy needs time to discuss his feelings before preoperative teaching is begun.
- Includes current nurse-prescribed and primary care provider-prescribed orders.
- Provides a summary of newly admitted patients, including diagnosis, age, general condition, plan of therapy, and significant information about the patient’s support people.
- Reports on patients who have been transferred or discharged from the unit.
- Clearly states priorities of care and care that is due after the shift begins. For example, in a 7 a.m. report, the nurse might say, “Mr. Li’s vital signs are due at 0730, and his IV bag will need to be replaced by 0800.” This information is best given at the end of that patient’s report because the receiver’s memory is best for the first and last information given.

- Is concise. Don’t elaborate on background data or routine care (e.g., do not report “Vital signs at 0800 and 1150” when that is the unit standard). Do not report coming and going of visitors unless there is a problem or concern or visitors are involved in teaching and care. Social support and visits are the norm.

SBAR

The SBAR technique, which was developed by the U.S. Navy, provides a framework for safe, efficient communication between members of the healthcare team. **SBAR** stands for:

- Situation
- Background
- Assessment
- Recommendation.

The tool provides an easy way to develop team cohesion and create a culture of patient safety (Institute for Healthcare Improvement, 2016). In the Situation step, the nurse provides a concise statement of the problem. In the Background step, the nurse relates information relevant to the situation. In the Assessment step, the nurse provides an analysis and consideration of options. And in the Recommendation step, the nurse provides a recommendation based on the relevant evidence. Using the SBAR technique during handoffs, transfers, and shift changes will reduce miscommunications that have the potential to cause patient harm, including those surrounding cultural considerations in patient care, as seen in the clinical example below. Improving communication skills among team members overall, and specifically in critical clinical situations, will help the nurse manager and the team improve patient safety and, in turn, team satisfaction.

Clinical Example H

Thomas Fullerton is a nurse in the postoperative recovery wing of a hospital. He is monitoring the vital signs of Mrs. Hussein, a 41-year-old woman who is recovering from a percutaneous endoscopic gastrostomy (PEG) placement earlier today. Thomas notices that Mrs. Hussein is having increasing dyspnea and complaining of chest pain, so he decides to alert the patient’s physician. Thomas provides the information in SBAR format. He calls the physician and states the situation: “Mrs. Hussein is experiencing dyspnea and complaining of chest pain.” Then, he provides background: “Mrs. Hussein had a PEG placement today, and a few hours ago she started complaining of chest pain. Her pulse is 122 and her blood pressure is 129 over 53. She is short of breath and restless.” Then, Thomas provides his assessment: “I think she may be having a cardiac event or a pulmonary embolism.” And finally, his recommendation: “I recommend that you see the patient as soon as possible and that we start her on O₂ stat.” See a condensed version of Thomas’s SBAR report in **Table 38–10** ».

Critical Thinking Questions

1. Would you have provided any information that Thomas did not? Why or why not?
2. Is the SBAR an appropriate format in which to convey this information? Can you think of any mistakes that Thomas avoided by using SBAR?
3. Explain why this phone call between Thomas and the physician is a kind of hand-off event.

TABLE 38–10 Example of an SBAR Report

Phase	Action
Situation	Provide description of the patient's dyspnea and chest pain.
Background	Provide an explanation that the patient had a PEG placement this morning and that relatively recently she began complaining of chest pain.
Assessment	Provide an assessment that the patient is most likely having a cardiac event or pulmonary embolism.
Recommendation	Provide a recommendation that the physician see the patient immediately and that the patient be started on an O ₂ stat.

» **Stay Current:** Learn more about the SBAR technique by visiting the website of the Institute for Healthcare Improvement to read the article titled “SBAR Technique for Communication: A Situational Briefing Model”: <http://www.ihl.org/resources/pages/tools/sbartechnequeforcommunicationasituationalbriefingmodel.aspx>.

SAFETY ALERT Employing effective communication techniques is essential throughout the nursing process, but communication may be most critical during reporting situations. If nurses do not receive adequate information from patients, provide the healthcare team with relevant details, and communicate effectively in groups, the patient's health may be jeopardized. Reporting techniques such as SBAR and handoff protocols are standardized techniques that streamline reporting safety.

Telephone Communication

Telephone Reports

Healthcare professionals frequently report about a patient by telephone. For example, a nurse informs the primary care provider about a change in a patient's condition, a radiologist reports the results of an x-ray study, or a nurse reports to a nurse on another unit about a transferred patient.

The nurse receiving a telephone report should document the date and time, note the name of the individual giving the information and subject of the information received, and then sign the notation. The individual receiving the information should repeat it back to the sender to ensure accuracy.

When giving a telephone report to a primary care provider, the nurse must be concise and accurate. Telephone reports usually include the patient's name and medical diagnosis, changes in nursing assessment, vital signs related to baseline vital signs, significant laboratory data, and related nursing interventions. The nurse should have the patient's chart ready in case the primary care provider requires further information.

After reporting, the nurse should document the date, time, and content of the call.

Telephone Orders

Physicians may order a therapy (e.g., a medication) for a patient by telephone. Most agencies have specific policies

about telephone orders. Many agencies allow only registered nurses to take telephone orders. The increased use of electronic records and communications is reducing the use of telephone orders, as electronic transmission of orders allows for greater accuracy.

While the primary care provider gives the order, the nurse should *write* the complete order down and *read* it back to the primary care provider to ensure accuracy. Question the primary care provider about any order that is ambiguous, unusual (e.g., an abnormally high dosage of a medication), or contraindicated by the patient's condition. Then transcribe the order onto the physician's order sheet, indicating it as a verbal order (VO) or telephone order (TO). Once transcribed onto the physician's order sheet, the order must be countersigned by the primary care provider within a time period described by agency policy. Many acute care hospitals require that this be done within 24 hours. Guidelines for telephone and verbal orders include:

1. Know the state nursing board's position on who can give and accept verbal and phone orders.
2. Know the agency's policy regarding phone orders.
3. Ask the prescriber to speak slowly and clearly.
4. Ask the prescriber to spell the name of the medication if you are not familiar with it.
5. Question the drug, dosage, or changes if they seem inappropriate for the patient.
6. Write down the order or enter it into the computer on the physician's order form.
7. Read the order back to the prescriber. Use words instead of abbreviations.
8. Have the prescriber verbally acknowledge the read-back.
9. Record the date and time and indicate it was a telephone order.
10. Sign your name and credentials.
11. Transcribe the order.
12. Follow agency protocol to have the prescriber sign the telephone order.

Also:

- When writing a dosage, always put a number before the decimal point, such as 0.5.
- Write out units, i.e., 20 Units versus 20 U.
- Never follow a voice-mail order. Call the prescriber, write the order down, and read it back for confirmation.

Care Plan Conference

Care plan conferences allow for collaborative reporting among the healthcare professionals who provide care to the patient. They are most often used for patients who have complex care needs. During the conference, the patient's healthcare providers discuss possible solutions to certain problems of the patient, such as an inability to cope with an event or lack of progress toward goal attainment. The care plan conference allows each member of the healthcare team an opportunity to offer an opinion in order to reach a solution to the problem. The choice of healthcare professionals who are invited to attend the conference is based on the needs of the patient. Family members are an important part of the care plan conference, especially for patients who are unable to advocate for themselves. Other professionals may

be invited. For example, a social worker may be present to discuss support for the family of a burned child or a pharmacist may be present at a conference when the patient requires multiple medications.

Care plan conferences are most effective when there is a climate of respect—that is, nonjudgmental acceptance of

others even though their values, opinions, and beliefs may seem different. Interprofessional collaboration is discussed further in the module on Collaboration. The nurse needs to accept and respect each individual's contributions, listening with an open mind to what others are saying even when there is disagreement.

REVIEW Reporting

RELATE Link the Concepts and Exemplars

Linking the exemplar of reporting with the concept of legal issues:

1. What are the legal obligations of a nurse who is providing change-of-shift reporting to the oncoming nurse?
2. How can the nurse ensure that all legal obligations have been met when accepting telephone orders from the primary provider?

Linking the exemplar of reporting with the concept of safety:

3. How does handoff communication contribute to patient safety?
4. In providing a telephone report to a primary care provider because of a patient's sudden change in condition, what information should be included to maintain the safe care of the patient?

REFER Go to Pearson MyLab Nursing and eText

- Additional review materials

REFLECT Apply Your Knowledge

Marjorie Newman, a 64-year-old woman, was admitted to the coronary care unit (CCU) with a diagnosis of acute anterior myocardial

infarction. Her condition has remained stable, and she is to be transferred to the telemetry unit tomorrow or sooner if the CCU bed is required for an acutely ill patient. The nurse assigned to her care is called to the monitors by the monitor technician because Ms. Newman has suddenly begun having frequent premature ventricular contractions (PVCs). When the nurse enters Ms. Newman's room, she assesses the patient and finds her to be short of breath, experiencing severe left-sided chest pain radiating to the left arm, and very diaphoretic. Vital signs are T_O 98.6°F; P 108 bpm and irregular; R 28/min; and BP 92/44 mmHg. The nurse analyzes Ms. Newman's rhythm strip and finds elevated ST segments, tachycardia, with 10–14 PVCs per minute. A coworker agrees to stay with Ms. Newman and monitor her condition while the nurse assigned to Ms. Newman's care calls the primary care provider.

1. What information would the nurse report to the primary care provider when calling to notify of the change in the patient's condition?
2. Why did the nurse have a coworker stay with the patient while calling the primary care provider?
3. How should the nurse report Ms. Newman's condition in the SBAR portion of the handoff report?

Module 39

Managing Care

Module Outline and Learning Outcomes

The Concept of Managing Care

Managed Care and Care Delivery Models

39.1 Analyze frameworks for delivering care.

Concepts Related to Managing Care

39.2 Outline the relationship between managing care and other concepts.

Managing Care Exemplars

Exemplar 39.A Case Management

39.A Analyze case management as it relates to managing care.

Exemplar 39.B Cost-Effective Care

39.B Analyze cost-effective care as it relates to managing care.

Exemplar 39.C Delegation

39.C Analyze delegation as it relates to managing care.

Exemplar 39.D Leadership and Management

39.D Analyze leadership and management as they relate to managing care.

>> The Concept of Managing Care

Concept Key Terms

Case management, 2616	Functional method, 2617	Patient-focused care, 2616	Shared governance, 2617
Case method, 2617	Licensed practical nurses (LPNs), 2618	Primary nursing, 2618	Team nursing, 2618
Differentiated practice, 2617	Managed care, 2615	Registered nurses (RNs), 2618	Unlicensed assistive personnel (UAP), 2618

Managed care is a healthcare delivery system that focuses on decreasing costs and improving outcomes for groups of patients. In this type of system, care is carefully planned from the initial contact with the patient through conclusion of the patient's specific health problem. Although exact methods used to manage care differ depending on the delivery model used, the overarching goals of lower costs and better outcomes remain constant.

Managed care is an important topic in modern nursing practice, because it shapes numerous aspects of the healthcare system. As payers search for ways to better contain rising costs, they continue to develop new incentives and standards, which in turn create trends in healthcare. Some of these trends have positive consequences, like an increased focus on preventive care. Others have the potential to create negative consequences, such as increases in hospital readmission following early release.

Within the managed care system, nurses may be involved in a variety of processes aimed at promoting high-quality

care for patients while maintaining cost effectiveness. Delegation is one such process; by distributing routine tasks to other staff members, nurses are able to devote more time to skills unique to or required of the registered nurse role. Care coordination and case management are other examples. Care coordination is a collaborative effort in which an interprofessional team provides cohesive care as a patient proceeds from hospitalization to recovery and health maintenance. The case manager coordinates and facilitates patient use of healthcare services in the long term. These processes eliminate redundancy and promote consistency, therefore lowering costs and improving quality. Successful delegation, care coordination, and case management depend on the ability of nursing leaders and managers to inspire staff, monitor patients, and adhere to organizational requirements. As a result, nurses' interpersonal skills are at the heart of good managed care.

Understanding the basics behind managed care is important for nurses as they move through their careers, no matter their level of leadership or managerial responsibility. Each

healthcare organization uses a particular model and understanding of managed care, and each organization layers its own goals, ethical standards, and legal requirements into its model of choice. Therefore, as nurses move from one organization or setting to another, they must have knowledge of these models in order to successfully care for patients and mature in their profession. With this requirement in mind, this module and its exemplars provide an introduction to the many facets of managed care.

Managed Care and Care Delivery Models

In managed care, healthcare providers and agencies work together to provide care that uses limited clinical resources wisely and effectively. Managed care strives to decrease unnecessary costs and increase patient satisfaction, in part by promoting health and delivering preventive services. Health maintenance organizations (HMOs) and preferred provider organizations (PPOs) are two examples of provider systems that are committed to managed care.

From the nurse's perspective, managing care is a learned process that requires strong communication, assessment, planning, and implementation skills (Leonard & Miller, 2012). The nurse's ability to apply these skills has important implications for direct patient care, coordination of care, and cost containment. For example, by scheduling the dietitian to meet with a patient at a different time than the physical therapist, the nurse makes sure that neither professional wastes time (and money) waiting for the other to finish seeing the same patient. This also may prevent the patient from becoming overtired by seeing too many providers within a short period. In addition to the skills mentioned above, effective managed care requires the abilities to prioritize, identify clinical pathways, and create concept maps and care plans. Information about these topics can be found in the module on Clinical Decision Making. The nurse must also understand patients' rights and advance directives and must be committed to quality improvement. The Advance Directives exemplar in the Legal Issues module, the Patient Rights exemplar in the Ethics module, and the Quality Improvement module include useful information on these topics.

From an organizational perspective, managed care has been embraced as a model for healthcare reform, but some people question the application of a business approach to something as personal and important as healthcare. Despite these concerns, many organizations have effectively combined managed care principles with a number of delivery models. As described in the following sections, each of these models requires nurses to draw upon their skills in different ways as they seek to promote patient well-being while controlling the costs of care.

Case Management

Case management is the coordination of patient care over time using the combination of health and social services necessary to meet the individual patient's needs. Case management is a fundamental element of many managed care systems. Case management offers intensive services, so it is most effectively and efficiently used for patients with multiple or complex chronic health problems (**Figure 39-1** »). For

Source: Carole Gomez/Vetta/Getty Images.

Figure 39-1 » Case management usually focuses on ongoing care of patients with chronic conditions or long-lasting problems, such as this patient who is receiving chemotherapy for cancer.

example, a patient with chronic obstructive pulmonary disease (COPD) who has just had hip replacement surgery would benefit from case management beginning at admission and continuing at the rehabilitation center or the skilled nursing facility to which he is discharged from the hospital.

Generally, case management involves interprofessional teams that collectively assume responsibility for planning and assessing the needs of groups of patients. These teams are also responsible for coordinating, implementing, and evaluating patient care from preadmission through discharge or transfer and recuperation. Each team is led by a case manager who is a nurse, social worker, or other appropriate professional. In some areas of the United States, case managers are referred to as discharge planners. These individuals may work for a patient's healthcare provider (e.g., clinic, hospital, or long-term care facility), insurance company, or perhaps even the patient's employer.

Patient-Focused Care

Patient-focused care is a delivery model that organizes healthcare around the expressed physical and emotional needs of the patient. This model incorporates concepts of patient- and family-centered care. Indeed, with this approach, patients and their families are considered integral components of the healthcare decision-making process.

In patient-focused care, the nurse takes time to learn about the patient's lifestyle, habits, and family. This includes being sensitive to diverse religious or cultural preferences. These preferences can impact diet, activity, and health practices, thus affecting patient adherence to the care regimen.

After gathering the necessary information about the patient's way of life, the nurse works with the patient to develop a plan of care that addresses both health and personal needs. As part of this plan, the nurse helps the patient acquire the knowledge and skills necessary to manage his or her health condition and make informed choices. The patient-focused model is based on the idea that care should be personalized and coordinated and that it should enable the patient to live as independent and fulfilling a life as possible (Health Foundation, 2014).

SAFETY ALERT With patient-focused care, the nurse should seek to honor the patient's preferences to the greatest degree possible. Still, the nurse has a duty to "do no harm." At no point should the nurse agree to a request that will potentially jeopardize the patient's well-being. Instead, the nurse should carefully and nonjudgmentally inform the patient of the risks associated with the requested practice or intervention.

Differentiated Practice

Differentiated practice is a system in which each nurse's educational preparation and skill sets are evaluated to determine how best to use the nurse. Thus, differentiated practice models consist of specific job descriptions for nurses according to their education or training—for example, LVN, ADN, BSN RN, MSN RN, and APN.

To establish a differentiated practice system, a healthcare organization must first identify the nursing competencies required by the patients it serves. The organization must also delineate the roles of licensed nursing personnel versus those of unlicensed assistive personnel (UAP). Such delineation enables nurses (as well as delegates) to assume roles and responsibilities appropriate to their level of experience, capability, and education. Differentiation maximizes the time and skill of individual staff members to help ensure that high-quality care is provided at an affordable cost.

Shared Governance

The **shared governance** model is used in concert with other models of care delivery. In this organizational model, members of the nursing staff participate with administrative personnel in making, implementing, and evaluating patient care policies. The focus of the shared governance model is to encourage nurses' participation in decision making at all levels of the organization.

With shared governance, individuals take part in decision making either at their own request or as part of their job role criteria. Typically, nurses participate by serving as members of decision-making groups, such as committees and task forces. The decisions made by these groups may address employment conditions, cost effectiveness, long-range planning, productivity, and wages and benefits. The underlying principle of shared governance is that employees are more committed to organizational goals if they provide planning and decision-making input.

Case Method

The **case method**, also referred to as *total care*, is one of the earliest nursing models. It is a patient-centered method in which one nurse is assigned to, and is responsible for, the

Source: Monkey Business Images/iStock/Getty Images.

Figure 39-2 >> The case method is often used in emergency departments.

comprehensive care of a group of patients during an 8- or 12-hour shift. For each patient, the nurse assesses needs, makes nursing plans, formulates nursing diagnoses, implements all care activities, and evaluates the effectiveness of care.

In the case method, a patient has consistent contact with one nurse during a shift but may have different nurses on other shifts. Considered to be the precursor of primary nursing (described later in the Concept), the case method continues to be used in a variety of practice settings, including emergency, acute, and intensive care units (**Figure 39-2** >>).

SAFETY ALERT Information gaps often develop when patients are transferred from one facility to another, such as when a patient moves from the hospital to a rehabilitation facility. They may also occur during nursing shift changes. Communication breakdown during the transfer or shift-change process can result in life-threatening situations for the patient. To help prevent such situations, be sure to carefully and completely document all care provided to the patient, as well as to verbally communicate with a patient's new nursing staff whenever possible.

Functional Method

The **functional method** focuses on the jobs to be completed as part of patient care (e.g., bed making and temperature measurement). In this task-oriented approach, personnel with less educational preparation than the professional nurse (e.g., UAP) perform aspects of care with less complex requirements. The method is based on a production and efficiency model that gives authority and responsibility to the person assigning the work (e.g., the head nurse). Clearly defined job descriptions, procedures, policies, and lines of communication are required.

The functional approach to nursing is economical and efficient, and it permits centralized direction and control. Its disadvantages include fragmentation of care and the possibility that nonquantifiable aspects of care, such as meeting the patient's emotional needs, may be overlooked.

Team Nursing

Team nursing is the delivery of individualized nursing care to a group of patients by a team led by a professional nurse. A nursing team consists of the following members:

- **Registered nurses (RNs)**, who are specially licensed and trained to deliver direct patient care, including patient assessment, identification of health problems, and development and coordination of care
- **Licensed practical nurses (LPNs)**, who provide direct patient care under the direction of an RN, physician, or other licensed practitioner
- **Unlicensed assistive personnel (UAP)**, or healthcare staff, who assume delegated aspects of basic patient care such as bathing, assisting with feeding, and collecting specimens. UAP include certified nurse assistants (CNAs), hospital attendants, nurse technicians, and orderlies.

In team nursing, the RN retains responsibility and authority for patient care but delegates appropriate tasks to the

other team members. Proponents of this model believe that the team approach increases the efficiency of the RN. Opponents believe that care of patients with acute illnesses requires greater attention from the professional nurse and allows little room for delegation.

Primary Nursing

Primary nursing is a delivery model in which one nurse is responsible for overseeing the total care of a number of patients 24 hours a day, 7 days a week, even if the nurse does not deliver all of the care personally. It is a method of providing comprehensive, individualized, and consistent care (Figure 39-3 >>>).

Primary nursing uses the nurse's technical knowledge and management skills. The primary nurse assesses and prioritizes each patient's needs, identifies nursing diagnoses, develops a plan of care with the patient, and evaluates the effectiveness of care (see the module on Clinical Decision Making). Associates provide some care, but the primary nurse coordinates it and communicates information about the patient's health to other nurses and health professionals.

Evidence-Based Practice

Nursing Ratio, Patient Outcomes, and Cost Effectiveness

Problem

The nursing ratio (i.e., the number of patients assigned to one nurse) in inpatient settings has long been thought to impact patient outcomes. The true impact of this ratio is difficult to quantify, however, because the nursing ratio is one of several components that can affect patient care. Addressing issues associated with the nursing ratio has the potential to influence the cost of care, which is a concern for organizations that adhere to the principles of managed care.

Evidence

Using objective measures such as the number of patients per nurse or the number of nursing hours per patient day, researchers have attempted to measure the impact of nursing ratios on patient outcomes. According to Mitchell (2012), higher nurse-to-patient ratios (assignment of fewer patients to one nurse) are linked with decreases in mortality, failure to rescue (failure to recognize and respond to a patient who is deteriorating), and specific adverse events among surgical patients. They are also associated with shorter lengths of stay and fewer complications. Lasater and McHugh (2016) further found that higher nursing ratios were associated with lower rates of hospital readmission following joint replacement surgery.

Kang, Kim, and Lee (2016) considered the way both the nursing ratio and the nonnursing responsibilities of nurses (e.g., housekeeping, patient transport, and food delivery) impact patient care. Their research revealed that the incidence of adverse patient events such as falls, healthcare-associated infections, and medication errors increased as nursing ratios decreased and nonnursing responsibilities increased. Roche et al. (2014) also explored the role nonnursing responsibilities play in provision of patient care. Their research suggests that increasing delegation of nonnursing responsibilities to UAP leads to improved quality of care, fewer incomplete tasks, and fewer delays in task completion.

Implications

Adverse events are detrimental to patients and increase the financial burden placed on the healthcare system. Research strongly

suggests that higher nursing ratios reduce the likelihood of such events, though Shekelle (2013) points out there has not been a formal evaluation of adverse outcomes within a single organization following a ratio increase.

Increasing nursing ratios may mean increasing staff size, which has the potential to raise healthcare costs. However, research by Martsof et al. (2014) suggests that increasing the nursing ratio by adding RNs results in a reduction of adverse event costs significant enough to offset the cost of additional staff. Pursuing delegation as a means of improving care also has the potential to increase costs if it involves hiring UAP, but as with RNs, decreases in adverse event costs may compensate for increases in UAP staffing costs.

Finding the right ratio of nurses to patients and the right mix of licensed and unlicensed staff has important implications for both patient care and healthcare costs. The ideal blend will vary from organization to organization, and it is affected by the care delivery model used. Evidence suggests that organizations committed to managed care stand to benefit from determining their ideal balance in both of these areas.

Critical Thinking Application

1. Evaluate how the loss of three licensed staff members from your unit might affect patient outcomes on the unit.
2. In the event that these staff members cannot be replaced, how would you, as the unit's director, prepare the remaining licensed and unlicensed personnel to prevent the most common adverse events that result from reductions in nursing staff?
3. In the event that these staff members cannot be replaced, what case management approach would you use to ensure that patients on your unit are adequately cared for and that their health is not jeopardized?

Source: Andresr/E+/Getty Images.

Figure 39-3 » The primary nursing model is often used in ICUs.

Primary nursing encompasses all aspects of the professional role, including teaching, advocacy, decision making, and continuity of care. The primary nurse is the first-line manager of the patient's care, with all accountabilities and responsibilities inherent in that role.

Concepts Related to Managing Care

Managed care is designed to provide cost-effective, high-quality care for groups of patients from the time of their initial contact with the health system through the conclusion of their health problem. Managed care relies on collaboration among the patient, the patient's family, and healthcare pro-

viders. Care coordination and case management are significant components of managed care.

Communication is a key concept in managed care, and it encompasses both communication within the healthcare team and communication between the care team and the patient. Clear communication among nurses, doctors, and other care providers ensures continuity in patient care, improving the patient's perception and experience of care and eliminating costly duplications. Communication among team members and patients creates a relationship based in trust and helps patients be informed and active participants in the care they receive.

To provide high-quality, effective care, the nurse must have a clear understanding of the best ways to manage personal time and patient time, as well as the best ways to work with the schedules of other professionals on the care team. Flexibility and patience are key to effective time management, as is a clear understanding of a patient's care priorities. These skills are learned through practice and lead to more efficient clinical decision making. They are discussed in more detail in the module on Clinical Decision Making. In addition, when making clinical decisions, nurses must be aware of the types of care that will be most beneficial for patients and advocate for that care when necessary.

Nurses maintain high ethical standards as they work with other members of the healthcare team to ensure that the care provided is cost effective yet meets the patient's needs and does no harm. The nurse must also assume the role of teacher in managed care in order to educate the patient and family about the patient's acute and ongoing healthcare needs after discharge. This teaching role is especially important because it helps the patient maintain health and reduce or avoid the costs associated with an acute exacerbation or recurrence of disease or injury.

Some, but not all, of the concepts integral to managing care are shown in the Concepts Related to Managing Care chart. They are presented in alphabetical order.

Concepts Related to Managing Care

CONCEPT	RELATIONSHIP TO MANAGING CARE	NURSING IMPLICATIONS
Advocacy	Nurses advocate to protect the rights of patients and defend patients from harm. Vulnerable populations depend on nurses to speak up for them as decisions about availability of healthcare services and resources are made.	<ul style="list-style-type: none"> Nurses work in a variety of healthcare settings with heterogeneous populations that need advocates to protect their rights. Nurse advocates empower and educate patients while managing their care.
Clinical Decision Making	Making decisions about patient care begins with analyzing assessment data to identify priorities of actions for best patient outcomes. Having a plan of care helps the nurse manage care by preventing duplication of services and communicating patient goals to other healthcare professionals.	<ul style="list-style-type: none"> Prioritizing care is a process nurses use to manage time and to establish an order for completing responsibilities and care interventions for a patient or group of patients. Competing priorities for care may mean initiating some interventions at a later time.

(continued on next page)

Concepts Related to Managing Care *(continued)*

CONCEPT	RELATIONSHIP TO MANAGING CARE	NURSING IMPLICATIONS
Communication	Communication among members of the collaborative team of healthcare providers is essential to ensure continuity of patient care. It also eliminates redundancy in testing and procedures. Therapeutic communication helps the patient learn about his or her condition and the care process.	<ul style="list-style-type: none"> Nurses direct communication within the collaborative team. They facilitate patient interactions with team members and coordinate care activities. In addition, they familiarize patients with their conditions and any necessary procedures. They also listen to patient concerns and answer patient questions.
Ethics	The ethical principles of altruism, autonomy, human dignity, integrity, and social justice influence decisions made in dispersing services and resources throughout healthcare systems.	<ul style="list-style-type: none"> Nurses need to provide patient-centered care to all patients in accordance with the common ethical nursing values of being truthful, promoting good, maintaining fairness, and doing no harm.
Healthcare Systems	Delivering and managing healthcare includes coordinating services and allocating resources as a means of meeting multiple patient needs and keeping costs in check. There is a need to close the gap between financial reimbursement and advances in medical interventions.	<ul style="list-style-type: none"> Nurses work with federal, state, and local guidelines in private and public healthcare settings to provide preventive, acute, chronic, and palliative care to patients. Adaptability, flexibility, and creativity are attributes nurses use to achieve good patient outcomes.
Teaching and Learning	Educating patients about their condition and health management is essential for enabling them to maintain health and avoid future complications. Mentoring staff members with less experience and familiarizing them with the components of managed care helps improve care delivery.	<ul style="list-style-type: none"> Nurses are primarily responsible for patient teaching; as such, they lay groundwork essential for keeping patients healthy and reducing the costs of care. Nurses also play an important role in helping other staff members develop their skills, particularly when tasks are delegated to less experienced staff members.

REVIEW The Concept of Managing Care

RELATE Link the Concepts

Linking the concept of managing care with the concept of communication:

- How does the nurse's ability to communicate effectively contribute to managing the patient's care?
- Describe a situation in which conflict management may be necessary when managing care for a patient who requires the services of several departments within a hospital.

Linking the concept of managing care with the concept of collaboration:

Mr. Montoya, a 54-year-old man, is to be discharged from an acute care facility after removal of a metastatic brain tumor. He will receive chemotherapy intrathecally as well as intravenously. The unit clerk has scheduled follow-up appointments with Mr. Montoya's surgeon, family provider, oncologist, and neurologist as well as with the infusion therapy department. The physician has provided referrals for consultation with a dietitian, social services, and home nursing care.

- How can the nurse prioritize care to meet Mr. Montoya's needs while also ensuring that all of the services provided (e.g., pre-discharge nutritional screening, social services interview, and home nursing assessment to determine home care needs) fulfill

the nurse's responsibilities to prepare Mr. Montoya for discharge?

- What is the nurse's role in managing Mr. Montoya's care and collaborating with the other members of the healthcare team?

REFLECT Apply Your Knowledge

John Seitz is the nursing director at a skilled nursing facility (SNF). He has received multiple complaints from patients and their families that care provided in one of the facility's units is inconsistent. For example, sometimes residents' trays are brought to the room but no one helps the residents eat. Similarly, beds often go unchanged, and baths are not always provided as requested by the residents.

- Evaluate what type of nursing model may work best in an SNF.
- Plan how you, as the nursing director, would ensure that the appropriate model is implemented by the facility's team members.
- What tools would you design and apply to evaluate the effectiveness of the new plan?

Exemplar 39.A Case Management

Exemplar Learning Outcome

39.A Analyze case management as it relates to managing care.

- Describe the purpose of case management and the role of the case manager.
- Identify key elements of case management.
- Explain the need for critical pathways in the case management process.

Overview

Case management describes a range of models for integrating healthcare services for individuals or groups. Generally, case management involves multidisciplinary teams that assume collaborative responsibility for assessing needs, planning and coordinating, implementing, and evaluating care for groups of patients from preadmission to discharge or transfer and recuperation. A case manager may be a nurse, social worker, or other appropriate professional. In some areas of the United States, case managers may be referred to as discharge planners. Key responsibilities of case managers include:

- Assessing patients and their homes and communities
- Coordinating and planning patient care
- Collaborating with other health professionals
- Monitoring patients' progress
- Evaluating patient outcomes

The **care management model** focuses on the needs of the integrated delivery system. It has many similarities to case management in that it also includes planning, assessment, and coordination of health services. However, this model focuses on populations instead of individual patients. The population of interest might be all people in a specific region, the members of a managed care plan, or a group of individuals who share a particular health characteristic, such as diabetes. The goal of the care management model is to integrate a continuum of clinical services. Care management is concerned not only with medical care but also with health promotion, disease prevention, cost control, and use of resources. Case management is often used within the care management model. Typical tools used to facilitate care management are critical pathways, disease management programs, and benchmarking.

Case management may be used as a cost containment strategy in managed care. Both case management and managed care systems often use critical pathways to track patient progress. A **critical pathway** is a standardized plan that helps track care provided to patients with similar, predictable medical conditions. Critical pathways are also called critical paths, clinical pathways, interprofessional plans, anticipated recovery plans, interprofessional action plans, or action plans.

Exemplar Key Terms

Care management model, 2621
 Care map, 2623
 Case management, 2621
 Critical pathway, 2621
 Patient-centered medical home (PCMH), 2621

The Nurse as Case Manager

As previously mentioned, case management takes a variety of forms within the U.S. healthcare system. For instance, with the **patient-centered medical home (PCMH)** model, a patient's primary care provider works with the patient and family to develop a personalized plan that addresses the patient's physical and mental health needs across the lifespan. In this model, the provider's office serves as a "home base" from which the patient can access comprehensive preventive, acute, and chronic care services in a manner specific to his or her needs, values, and cultural and linguistic preferences (Patient-Centered Primary Care Collaborative, n.d.). Of course, provider-based case management also occurs in other settings. For example, hospital-based case managers plan and coordinate pre- and postdischarge care for patients with chronic or complex conditions, while community-based case managers work with patients in their homes to ensure they receive adequate ongoing care. In addition, many insurance companies and even some large employers have case managers on staff in an effort to control costs while obtaining better health outcomes.

Regardless of the exact setting, a high percentage of case manager positions are filled by registered nurses. Ideally, nursing case managers have advanced degrees and considerable clinical experience in nursing. These qualifications are crucial in that nurse case managers coordinate all aspects of care, advocate for patients at each stage of care, and plan an overall strategy to address each patient's problems. In an acute care setting, the case manager typically has a caseload of 10 to 15 patients and follows the patients' progress through the system from admission to discharge, accounting for variances from expected progress. Nursing case managers on a patient care unit may coordinate, communicate, collaborate, problem solve, and facilitate patient care for a group of patients and supervise the direct care that other nurses and UAP provide.

Clinical decision making and critical thinking skills are crucial to the development and execution of a well-coordinated care plan. The nurse assesses the patient's needs holistically to ensure that those needs are met and that the patient's independence and quality of life are maximized. The nurse also explores available resources to assist the patient with achieving or maintaining homeostasis and

independence, including determining what materials or equipment (such as oxygen or assistive devices) the patient may need.

Actual and potential problems should be identified during care plan development. The nurse is responsible for identifying potential coordination challenges and ensuring that those challenges are addressed during the development phase. For example, challenges may arise related to a patient's religious practices, cultural beliefs and practices, or use of complementary approaches. The nurse assesses for any potential conflicts and works with the patient and the healthcare team to resolve them to ensure the provision of safe, appropriate care and the best possible outcomes for the patient.

The nurse must also ensure that planned care follows standard protocols or critical pathways and evidence-based guidelines. After evaluating the patient's care needs, the nurse organizes the required components of care and develops the nursing care plan in consultation with the patient. The care plan then serves as the nurse's framework for care coordination.

The nurse case manager initiates consultation with the interprofessional care team, recognizes the needs for referral, and obtains necessary orders. As consultations and referrals are implemented, the case manager updates the critical pathway and informs the other members of the interprofessional team. On an ongoing basis, the nurse communicates with patients, family members, and members of the healthcare team to ensure that the plan is executed and continues to meet the patient's needs. It is critical that the nurse coordinator monitor the plan execution and follow up with the patient, family, and team members when adjustments are needed. When necessary, the nurse revises the care plan. Changes in a patient's condition and plans to discharge or transfer the patient are automatic flags that the plan must be updated. The nurse is responsible for documenting the original care plan and any modifications.

Key Elements of Case Management

Nursing case management organizes patient care by major diagnoses or *diagnosis-related groups* (DRGs). DRGs allow nurses to work toward predetermined patient outcomes within specific time frames and resource allocations.

Nursing case management requires the following:

- Collaboration of all members of the healthcare team
- Identification of expected patient outcomes within specific time frames
- Use of principles of continuous quality improvement (CQI) and variance analysis
- Promotion of professional practice
- Promotion of cost-effective care

Research suggests that case management has been particularly successful in disability management, especially when applied to helping injured employees to return to work (Gardner et al., 2010). Likewise, home care and ambulatory settings lend themselves to case management. Patient

involvement and participation are key to successful case management (Summers, 2012).

To initiate case management, specific patient diagnoses that represent high-volume, high-cost, and high-risk cases are selected. High-volume cases are those that occur frequently, such as total hip replacements on an orthopedic floor. High-risk cases include patients or case types who have complications, stay in a critical care unit longer than 2 days, or require ventilatory support. Patients also may be selected because they are being treated by a physician who supports case management. Whatever patient population is selected, baseline data must be collected and analyzed. These data provide the information necessary to measure the effectiveness of case management. Essential baseline data include length of stay, cost of care, and complication information.

Five elements are essential to successful implementation of case management:

1. Support by key members of the organization (administrators, physicians, nurses)
2. A qualified nurse case manager
3. Collaborative practice teams
4. A quality management system
5. Established critical pathways (see next section)

When a specific patient population is selected to be “case managed,” a collaborative practice team is established. The team, which includes clinical experts from appropriate disciplines (e.g., nursing, medicine, physical therapy) needed for the selected patient population, defines the expected outcomes of care for that population. Based on expected patient outcomes, each member of the team, using that member's discipline's contribution, helps determine appropriate interventions within a specified time frame.

In case management, all professionals are equal members of the team; thus, one group does not determine interventions for other disciplines. All members of the collaborative practice team agree on the final draft of the critical pathways, take ownership of patient outcomes, and accept responsibility and accountability for the interventions and patient outcomes associated with their discipline. The emphasis must be on managing patient outcomes and building consensus among team members. Outcomes must be specified in measurable terms.

Clinical Example A

Martha Ellison is an RN with 10 years of experience and a master's degree in nursing. She is the case manager on the orthopedic unit of the city hospital. She is currently managing 10 patients on the unit: four with injuries that resulted from car crashes; two older adults, each with a fractured hip; and four adolescent patients who required placement of pins and traction to stabilize fractures. Ms. Ellison compares each patient's progress to the critical pathway for that patient and makes recommendations to the physician managing their care related to meeting specific needs.

One of the patients in Ms. Ellison's care is a 22-year-old man who experienced significant head injuries and multiple fractures as a result of a motor vehicle crash. Ms. Ellison works with the hospital physical therapy department to optimize his mobility and range of motion in order to prepare him for rehabilitation. She collaborates with a

rehabilitation center that will continue his care following discharge. Ms. Ellison also collaborates with the neurologist and family care providers to ensure that the patient's other needs are met and he is able to be discharged as soon as possible.

Critical Thinking Questions

1. Identify the different individuals and organizations with whom Ms. Ellison is collaborating. Explain why collaboration is essential to meeting a patient's needs.
2. What is the purpose of a critical pathway? What are some other names for a critical pathway?
3. In the care of patients with orthopedic injuries, explain how case management for the older adult patient might differ from that needed for the younger adult patient.

Critical Pathways

Successful case management relies on critical pathways to guide care. The term *critical pathway*, also called a **care map**, clinical pathway, or critical path, refers to the expected outcomes and care strategies developed through collaboration by the healthcare team. Again, the interprofessional team must reach consensus regarding patient care and determine specific, measurable outcomes.

Critical pathways provide direction for managing the care of a specific patient during a specified time period. Critical pathways are useful because they accommodate the unique characteristics of the patient and the patient's condition while making use of the predictable characteristics of the course of the patient's disease or injury. Critical pathways use resources appropriate to the care needed, thereby reducing cost and length of stay. Critical pathways are used in every setting where healthcare is delivered.

A critical path quickly orients the nurse to the outcomes that should be achieved for the patient for that day. Nursing diagnoses identify the outcomes needed. If patient outcomes are not achieved, the case manager is notified and the situation is analyzed to determine how to modify the critical pathway.

Altering time frames or interventions is categorized as a variance, and the case manager tracks all variances. After a time, the appropriate collaborative practice teams analyze the variances, note trends, and decide how to manage them. Teams may then revise the critical pathway or decide to gather additional data before making changes.

Some features are included on all critical paths. These include the specific medical diagnosis, the expected length of stay, patient identification data, appropriate time frames (in days, hours, minutes, or visits) for interventions, and patient outcomes. Interventions are presented in modality groups (medications, nursing activity, and so on). The critical path must include a means to identify variances easily and to determine whether outcomes are met.

» **Stay Current:** Clinical pathways vary according to patient needs, agency protocols, and current best practices for care. Examples of clinical pathways can be found at the website of the Children's Hospital of Philadelphia: <http://www.chop.edu/pathways#.V5JSfc-v6uM8> and at the University Health System, San Antonio, Texas: <http://www.universityhealthsystem.com/services/pharmacy/clinical-pathways-guidelines>

Case Management Across the Lifespan

Case management can yield positive results for patients of all ages and with any number of health concerns. However, some patients are more likely to benefit from case management than others. Prominent examples of such patients include at-risk pregnant women; children with congenital conditions or other special needs; children, adolescents, and adults with behavioral, intellectual, or mental health problems; and older adults who have chronic conditions or are approaching the end of life.

At-Risk Pregnant Women

Maternity case managers specialize in working with women who have one or more health-related, social, or economic factors in their lives that place them at increased risk for problems during pregnancy or childbirth. For example, a woman might benefit from maternity case management if she has a chronic disease, uses drugs or alcohol, is experiencing mental illness, lives in extreme poverty, and/or is involved in an abusive relationship. In such cases, the maternity case manager can help promote the health of mother and infant alike by ensuring receipt of adequate prenatal care and referring the patient to various community and government services as appropriate. The case manager also plays a critical role in educating the woman about topics such as obtaining proper nutrition and exercise during pregnancy; recognizing perinatal mood disorders; avoiding fetal exposure to alcohol, tobacco, and drugs; understanding the benefits of breastfeeding; and reducing the risk of maternal-fetal disease transmission at birth.

Children with Special Needs

Many children sustain physical and/or mental disability as a result of premature delivery, congenital disease, birth injury, childhood illness, or some other cause. Case managers are a valuable resource for these children and their families, not only at the time of the initial diagnosis or injury, but for months and sometimes years afterward.

For those children whose conditions can be remedied by surgical and other means (e.g., those with correctable heart or musculoskeletal defects), case managers help plan and coordinate the medical procedures required to correct the problem. They also arrange for the child and family to receive other services necessary to support their well-being throughout the entire treatment period, such as physical and occupational therapy, psychologic counseling, pharmacotherapy, and in-home nursing care.

For children whose conditions will persist for the rest of their life, case managers perform a similar set of actions. However, in addition to coordinating medical care and connecting patients and their families with available support services, they also work to ensure that the child receives adequate educational and other accommodations throughout childhood. Frequently, this requires the case manager to engage in advocacy efforts on behalf of these patients.

Patients with Behavioral, Intellectual, or Mental Health Problems

Patients of all ages may be affected by behavioral, intellectual, or mental health problems that limit their ability to participate in school, obtain or retain a job, engage in self-care, live independently in the community, or engage in any number of other activities of daily living. After working with these individuals to determine their unique limitations, case managers can help each patient formulate a set of realistic goals and expectations, then connect the patient with any number of resources necessary for meeting these goals. Examples include (but are not limited to) individual and/or group counseling; vocational training and structured workshops; nutritional services; disability advocacy organizations; group homes; housekeeping services; home care aides; transportation services; assistive technology; and resources for ensuring adherence with pharmacologic and other therapeutic regimens.

Older Adults

Case management is often a critical component of care for older adult patients. One reason is that many older adults experience multiple and/or chronic health conditions that require ongoing care and coordination. For patients like these, case management helps promote continuity of care, prevent duplication of services, and ensure that patients are not receiving therapies that counteract or otherwise work against one another. In this way, case management helps

promote better patient outcomes while simultaneously fostering more efficient, cost-effective use of healthcare resources.

Case management is also an increasingly common aspect of end-of-life care for many older adults (as well as patients of any age who are affected by terminal illness). By working closely with these individuals and their families, case managers help ensure that their patients are able to achieve death with dignity. This means that patients are empowered to choose which treatments they wish to receive without feeling pressured to undergo potentially painful and/or expensive treatments that may only minimally extend their lifespan, yet they are not automatically precluded from receiving these treatments if they so choose. It also means that patients are able to die in the place of their choosing and/or in the presence of loved ones. Often, the case manager's first step in ensuring a patient's wishes are met is to simply speak honestly with the patient about his or her health and impending mortality—something that many healthcare providers and family members are reluctant to do. From this foundation of honesty and understanding, the case manager and patient can together explore options for many end-of-life decisions, including choices related to hospice, palliative care, financial affairs, advance directives, power of attorney, and other medical and legal concerns. The case manager can also help the patient and family arrange for grief counseling and other forms of emotional and spiritual support (Fink-Samnicks, 2016; Meyer, 2012).

REVIEW Case Management

RELATE Link the Concepts and Exemplars

Linking the exemplar of case management with the concept of perfusion:

1. A neonate born with a severe congenital heart defect will require numerous open heart surgeries and regular follow-up with cardiology and pediatrics. The parents, who carry comprehensive medical insurance, will require assistance paying for medical bills because the cost of care is expected to exceed the child's lifetime maximum coverage within a few years. How might this family benefit from case management? What specifically would the case manager do for this family?

Linking the exemplar of case management with the concept of oxygenation:

2. The nurse is caring for two patients. One patient has pneumonia that is resolving with IV antibiotics; the other patient has had asthma for many years. Which patient would benefit most from case management? Explain your answer.
3. The nurse is caring for a patient with a chronic alteration in oxygenation requiring many different medications, frequent physician visits, and a history of two to three hospital admissions per year. How might case management help this patient?

REFLECT Apply Your Knowledge

Curt Ranier is a 42-year-old man who sustained a right femur fracture during a motor vehicle crash. Following surgical repair of his femur fracture, he is admitted to the orthopedic unit. Mr. Ranier's surgery and anesthesia were uneventful, and he is stable and alert. His medical history includes type 2 diabetes, which he manages through his diet. He also has a prior history of deep vein thrombosis (DVT) in his left leg. During his admission to the orthopedic unit, Mr. Ranier expressed his motivation to heal and go home; however, he states that he is concerned about caring for himself outside the hospital setting, as he lives alone and has no relatives nearby.

1. Considering Mr. Ranier's current condition and medical history, which nursing diagnoses (both actual and risk) should be included in his nursing plan of care?
2. How would Mr. Ranier benefit from case management? In addition to nursing, describe several other professional disciplines that should collaborate in Mr. Ranier's care.
3. Describe the benefits of using a critical pathway to guide Mr. Ranier's care. In addition to Mr. Ranier's medical diagnosis and patient identification data, identify three categories that would be included in Mr. Ranier's critical pathway.

Exemplar 39.B Cost-Effective Care

Exemplar Learning Outcomes

39.B Analyze cost-effective care as it relates to managing care.

- Summarize payments sources in the United States.
- Describe the international perspective of healthcare.
- Outline factors influencing the provision of healthcare.
- Describe cost-containment strategies.
- Summarize the economics of nursing.

Overview

Despite efforts to control costs, healthcare spending grew at an average annual rate of 4.6% during the period from 1960 to 2010. However, that rate slowed considerably between 2010 and 2013, dropping to 1.1% average annual growth (Council of Economic Advisers, 2014). In 2013, the Secretary of Health and Human Services, Kathleen Sebelius, commented on the change as follows:

For years, health care costs have been rising faster than inflation, driving up the cost of health care and making it less affordable for families and businesses. But now, the good news about the slowing growth of health care spending nationwide is being increasingly recognized by independent analysts. . . . According to an analysis conducted by *USA Today* (2013), “health care spending last year rose at one of the lowest rates in a half-century.” Further, health care providers and analysts found that “cost-saving measures under the health care law appear to be keeping medical prices flat.”

Employers, legislators, insurers, and healthcare providers continue to collaborate in efforts to resolve issues surrounding how to best finance healthcare costs. Among these efforts, the United States has implemented several cost-containment strategies, including health promotion and illness prevention activities; managed care systems, including care coordination; and alternative insurance delivery systems.

Payment Sources in the United States

Payment for healthcare services in the United States may come from one or more of several sources. For example, an older patient may have Medicare and supplemental healthcare coverage purchased from a private insurance company; if this combination does not cover all costs, the patient may have to cover the remaining amount with his or her own money. Insurance is often classified as **public insurance** (insurance financed by the government) or **private insurance** (insurance provided by private or publicly owned companies

such as Blue Cross Blue Shield, Kaiser Permanente, or Aetna). Many insurance plans, public or private, include a per-visit or per-prescription copayment and a deductible. Medical payment sources in the United States are discussed in greater detail in the module on Health Policy.

The International Perspective

A society’s widely held values and attitudes (e.g., toward the government’s role in private lives) influence the development of its healthcare systems and policies. Most developed countries outside of the United States have similar values with regard to healthcare; the United States is unique in its emphasis on self-reliance, self-determination, and limited government involvement. **Table 39-1** » contrasts U.S. values in relation to healthcare with those of other countries.

Each country has its own unique healthcare system, but these systems can be broadly divided into four categories based on the organization and financing of healthcare:

- The first category is **socialized medicine**, in which the state owns and controls healthcare services. Examples of socialized medicine are seen in the United Kingdom, Sweden, and Denmark, where physicians derive virtually all of their income from the government and have employment contracts with the state.
- The second category is **socialized insurance**, in which all medically necessary services are covered by the government (including physician care, hospital services, and to some extent, prescription drugs), but these services are delivered by a blend of private and public providers. Canada, France, and Australia have this form of healthcare system.
- **Mandatory health insurance** is the third category and is found in Germany and Japan. These nations have large, nonprofit health insurance organizations called “sickness funds.” The sickness funds are usually organized around large employers or work-based associations. Government-sponsored programs cover citizens who are not part of a sickness fund. Everyone belongs to one of these two types of plans, thus ensuring universality of coverage.

TABLE 39–1 Comparison of Healthcare Values in the United States and Other Developed Countries

United States	Other Developed Countries
Pluralism and choice	Universality
Self-reliance	Shared responsibility
Emphasis on individual freedom	Acceptance of the role of government
Federalism	Centralization
Free enterprise	Equity
Fear of rationing	Acceptance of system constraints

(2012). *U.S. view of health care at odds with Europe*. Retrieved from <http://www.marketwatch.com/story/us-view-of-health-care-at-odds-with-europe-2012-08-02>.

- Finally, **voluntary insurance** provides no guarantee of universality because coverage may be expensive and difficult to purchase. The United States currently has this type of system, under which millions of Americans lack coverage due to financial and other constraints (see Focus on Diversity and Culture: Health Insurance and Socioeconomic Status). A major goal of the Patient Protection and Affordable Care Act, signed into law in March 2010 and often referred to as the ACA or “Obamacare,” was to reduce the difficulties associated with securing voluntary insurance in the United States. Under the ACA, the majority of individuals who did not have health insurance through their employer or a government program were required to purchase coverage or pay a financial penalty. To make such coverage more accessible and affordable,

the ACA established subsidies for some Americans and called for the establishment of health insurance exchanges in all 50 states. Thus, the ACA attempted to move the United States toward a mandatory insurance system while still allowing people to opt out as long as they are willing to pay the associated penalty.

Note that both socialized medicine and socialized insurance are considered **single-payer systems**, because payment for all services ultimately comes from one source (i.e., the national government). In contrast, the mandatory and voluntary insurance systems are both considered **multi-payer systems** in that reimbursement is provided by a combination of sources (Ridic, Gleason, & Ridic, 2012).

Regardless of their exact form, healthcare systems throughout the world are in crisis. Most countries, regardless of their level of funding for healthcare, have run out of ways to finance their expenditures through taxation or other existing channels. They realize that costs must be contained in the future. Furthermore, there is concern in western European nations, Canada, and Australia about the increased sophistication and resulting expectations of their emerging middle classes.

Factors Influencing the Provision of Healthcare

A number of factors influence provision of and access to healthcare, regardless of the types of coverage available. Within the United States, economic factors including supply and demand and the inability to account for the actual costs of critical services (e.g., nursing services) are important influences on the provision of healthcare.

Supply and Demand

In the 1980s, an imbalance in supply and demand emerged as the cost of medical care began increasing faster than the

Focus on Diversity and Culture

Health Insurance and Socioeconomic Status

Health insurance is a major determinant of access to care—and in the United States, health insurance coverage is strongly tied to socioeconomic status.

Despite progress made in the numbers of insured individuals as a result of ACA, tens of millions of Americans continue to lack even basic healthcare coverage, and low-income families and minority groups continue to be disproportionately affected. For example, in 2014:

- More than 80% of uninsured Americans came from families in which at least one member worked.
- More than 50% of uninsured Americans came from low-income households, defined as those with a combined family income below 200% of the poverty level. (In 2014, the federal poverty level for a family of three was \$19,055.)
- People of color accounted for over half of the nation's uninsured, even though they made up only 40% of the overall U.S. population. Uninsured rates were especially high among Hispanic Americans (20.9%) and non-Hispanic Black Americans (12.7%) as compared to White Americans, who had an uninsured rate of 9.1% (Kaiser Family Foundation, 2015).

A variety of socioeconomic factors place low-income and minority individuals at elevated risk for health problems—and lack of insurance only increases this risk. In fact, research indicates that about 27% of uninsured adults went without needed healthcare in 2014 because they couldn't afford the cost. Furthermore, even when they aren't sick, the uninsured are less likely to receive preventive care. As a result of this care deficit, uninsured Americans are more likely to experience catastrophic illness and less likely to afford treatment when they can no longer postpone it. The resulting increases in resource-intensive and uncompensated care drive up costs across the entire healthcare system (Kaiser Family Foundation, 2015).

These statistics also underline the importance of containing costs within nursing units and throughout care organizations as a means of improving the affordability of care. Making care more affordable for patients with low socioeconomic status will improve health and reduce suffering. It will also save money in the long run by eliminating costly complications associated with conditions that are preventable or more easily treated in the early stages.

gross national product. During this time, consumers came to expect that any and all services, regardless of cost, should be available and paid for by third-party payers. As a result, the price of insurance coverage in the private sector skyrocketed, creating further imbalance.

Today, many employers cannot or will not provide the same level of healthcare coverage to employees as in years past. Most employers now require their employees to pay a greater portion of the cost of insurance in the form of increased premiums. Others do not provide health insurance coverage at all. These changes diminish the ability of all consumers to afford care, yet many Americans continue to expect care on demand. From a healthcare economics standpoint, this has created a situation in which healthcare cannot be supplied at the level demanded by the public (Health Resources and Services Administration, 2013; Hoffman, 2013).

When there is an imbalance in supply and demand, rationing of healthcare may result. No country can afford to provide unlimited amounts of medical services to everyone, so each nation must decide how to ration, or limit access to, healthcare services. This can happen in two ways. The first is by having the government set limits. In this approach, the cost of services is kept low, and people wait for availability. This type of rationing is used in several industrialized countries, including Great Britain and Canada. Scarce services are kept at a reasonable cost but are allocated according to particular criteria, such as age or a waiting list. Even in these countries, however, individuals who can pay for more services have access to more services. In the United States, only Oregon has suggested such an approach. The Oregon legislature enacted a program to limit access to expensive procedures, such as transplantation, and then increase Medicaid eligibility to a larger number of low-income people. The second approach to healthcare rationing is to ration by ability to pay. This approach limits demand for more expensive procedures by offering them only to those who are willing and able to pay out of pocket or who have sufficient health insurance coverage (Hoffman, 2013).

There are important differences between these two rationing methods. One major difference involves the freedom of individuals to choose the amount and type of healthcare they use and to select who should deliver it. Freedom of choice is a traditional value of healthcare consumers in the United States. Under a system of strict government rationing, a patient cannot purchase a particular healthcare service unless it is made available to everyone by the government. Conversely, under the ability to pay method, a patient can theoretically purchase any healthcare service as long as he or she can afford it. For those who cannot afford a particular service, however, that service is not an option, no matter how great the individual's need.

SAFETY ALERT Under federal law, patients who are experiencing a true medical emergency cannot be denied treatment, regardless of their ability to pay. Specifically, the Emergency Medical Treatment and Labor Act (EMTALA) of 1986 requires all Medicare-participating hospitals that offer emergency services to examine and stabilize any patient who presents for an emergency medical condition, even if that patient cannot pay for services. Once the patient is stabilized, however, EMTALA protections no longer apply, and the patient may be transferred or discharged at the hospital's discretion.

Separate Billing for Nursing Services

Within the United States, bills submitted to third-party payers and consumers from healthcare organizations (e.g., hospitals) continue to bundle nursing services with flat daily charges (e.g., the cost of the room and housekeeping). The specific cost of nursing has neither been separated out nor given a dollar value. This bundling has hindered nurses' ability to receive payment from third-party payers. Many nursing leaders think that in order for nursing to be a profession, nursing services must be accounted for separately by healthcare institutions.

Several developments within the nursing profession have provided ways of quantifying nursing care. Some of the better-known projects have resulted in nursing diagnoses that can be used to categorize nursing interventions; these include the NANDA International (NANDA-I) diagnoses, the Nursing Interventions Classification (NIC), and the Nursing Outcomes Classification (NOC). The recent development of payment codes for care coordination is another example of such developments. Proponents of these systems argue that quantifying nursing care will help control costs by ensuring that patients pay only for the exact level of nursing care they require. Quantification of care will also provide useful data that allow facilities and providers to better track the cost effectiveness of various nursing actions, as well as allocate nursing resources in the most efficient way possible (Rutherford, 2012).

Cost-Containment Strategies

Over the past few decades, a number of strategies have been developed in an attempt to contain healthcare costs. Some of the most prominent cost-containment strategies are competition, price controls, and alternative insurance delivery systems. Managed care, health promotion and illness prevention, alternative care providers, and vertically integrated health service organizations are also popular. In addition, since its enactment in 2010, the ACA has put several cost-containment strategies in place. Various measures aimed at controlling the costs of care are discussed in the sections that follow.

Competition

During the 1970s, regulations in the United States were changed to permit competition among organizations that deliver healthcare and provide insurance. Currently, little reduction in costs appears to be attributable to competition. Competition has, however, led to the establishment and expanded use of walk-in clinics, urgent care clinics, and alternative healthcare providers (such as advanced practice registered nurses), all of which offer additional care choices for patients.

Price Controls

Price controls for healthcare services have been established in various ways. Freezes on physicians' fees have been imposed at various times for short periods and, as mentioned previously, many states limit reimbursement to physicians and hospitals for services provided to Medicaid patients.

The passage of the Tax Equity and Fiscal Responsibility Act (TEFRA) in 1982 brought about a dramatic restructuring of healthcare delivery in the United States. Through this act, the federal government changed the payment method for

Medicare from a retrospective system to a prospective one. In a retrospective payment system, billing is determined after services are rendered; in a **prospective payment system (PPS)**, billing is determined before the patient is ever admitted to the hospital. By making Medicare payments prospective, TEFRA limits the amount of Medicare reimbursements paid to hospitals. Limits are set using a system of **diagnosis-related groups (DRGs)**, by which hospitals are paid a predetermined amount for patients with a specific diagnosis. For example, a hospital that admits a patient with a diagnosis of myocardial infarction is reimbursed for a specific dollar amount, regardless of the cost of services, the length of stay, or the acuity or complexity of the patient's illness. DRG rates are set in advance of the year during which they apply and are considered to be fixed unless major, uncontrollable events occur.

Unfortunately, this type of PPS may result in healthcare agencies choosing to withhold borderline necessary tests and procedures and shorten hospital stays, thus avoiding the expenditures a prolonged stay generates. Doing so allows hospitals to keep their costs at or below the amount they are allowed to bill Medicare. Notable effects of these practices include the earlier discharge of patients, decreased admissions, increased outpatient services (both type and number), and increased focus on the costs of care. Earlier discharge of patients has led to expanded home care services and increased use of technology and specialists.

Another means of reducing healthcare costs is the development of group self-insurance plans. These plans are created for a designated group, such as employees in a large company, a group of companies, or a union. The designated group then assumes all or part of the costs of healthcare for its members. Group plans can often provide coverage at a lower cost than insurance companies because they are exempt from certain taxes and fees.

Cost-containment strategies such as PPS and group self-insurance plans have driven several trends in healthcare delivery. These include increased emphasis on preventive care to reduce the incidence of illnesses, provision of treatment in noninstitutional settings such as clinics or patients' homes, and use of best practices as documented in protocols and guidelines. These strategies focus on avoiding hospital and institutional placement unless absolutely necessary and ensuring that all care provided is scientifically based.

Vertically Integrated Health Services Organizations

Yet another cost-containment practice that has become increasingly common in recent decades is the establishment of *vertically integrated health services organizations*, or networks of hospitals, clinics, and individual providers that offer a broad range of care and support services to patients across the entire wellness spectrum. By integrating the provision of hospital care, ambulatory care, outpatient surgery, and home health services, these systems allow patients to receive the precise level of care they need in the most cost-effective way possible.

Two trends have contributed to the rise of vertically integrated health services organizations: the change in payment structures and the development of medical technology. As insurers became more concerned about the rising costs of healthcare during the 1970s, hospitals began to integrate

horizontally to form multiple-hospital systems. By coordinating services within each system, hospitals were able to avoid duplication of services as well as underuse of expensive equipment at multiple sites.

The move to vertical integration began several years later as a result of TEFRA's creation of fixed Medicare payments based on DRGs. This legislation prompted hospitals to begin monitoring discharge practices and lengths of stay. Hospitals soon realized that patients could be discharged earlier to other suitable settings, such as nursing homes, rehabilitation centers, and their own homes. Earlier discharges were more cost effective. At the same time, hospitals realized it would be advantageous for them to own or contract with agencies that provide other levels of care. This vertical integration allowed hospitals to reduce inpatient costs and receive additional Medicare revenues.

Advances in medical technology have also contributed to the move from traditional inpatient hospitalization to outpatient settings. The length of hospital stay for many surgeries, such as cholecystectomies, hernia repairs, and some orthopedic surgeries, was once several days. New technologies now permit these surgeries to be performed on an outpatient or ambulatory surgery basis at less expense.

The goal of vertical integration is to create a "seamless" system of patient care in which movement from service to service is coordinated and well organized. Such a system improves outcomes and quality of care while increasing patient satisfaction and providing better cost control through more efficient use of resources. If a vertically integrated system is efficient, it can decrease transaction costs and allow greater accountability.

Cost Containment and the ACA

The ACA legally compelled healthcare organizations to adopt various cost-containment measures aimed at improving the quality of care provided, redesigning healthcare delivery systems, determining appropriate payment for services provided, modernizing the financial systems used to pay for services, and eliminating fraud and abuse. For example, the law established payment penalties as an incentive to prevent hospital readmissions and healthcare-associated conditions such as pressure injuries and infections. The ACA also called for provision of coordinated care by healthcare teams rather than individual providers and mandated reduction of medically unnecessary services that may be detrimental to a patient's health.

Nursing Economics

Quality of care and cost trade-offs in hospitals have dominated the literature for the past decade. Both consumers and healthcare professionals have expressed concerns about diminished quality of care resulting from cost constraints, early discharge, periodic nursing shortages, and increased use of UAP.

Determining the precise cost of services is a major challenge for nursing. What are the exact costs of high-quality nursing care? How many nursing care hours are required for each DRG? What is the best skill mix—that is, ratio of RNs to LPNs to UAP—on each hospital unit? Since 1983, many studies have sought to determine the actual costs and cost effectiveness of nursing care. Researchers have investigated such topics as the impact of nurse–physician collaboration;

new cost-effective interventions; the cost benefits of primary nursing, nurse practitioners, and nurse-midwives; and the cost effectiveness of home care. The quality of the nursing care of the future relies on ongoing research in the area of economics, as well as nurses' awareness of economic issues during the course of their daily practice.

Nursing Shortages

One factor that must be considered when discussing the economics of nursing in the United States is the impact of nursing shortages. One measure commonly used to gauge whether a shortage exists is the *nursing vacancy rate*, or the percentage of unfilled nursing positions for which an organization is recruiting.

When shortages occur, employers are forced to compete for the same available pool of nurses, which means they must increase wages in order to hire and retain staff. As employers fill positions and more nurses enter the workforce as a result of other factors, employers begin to slow the rate at which they increase wages. These shortage-linked salary fluctuations contribute to the challenge of determining the actual costs of nursing.

Trends in healthcare during the past 20 years have further contributed to the complexity of the problem. Because of the shift toward decreased lengths of stay, patients are often sent home "sicker and quicker." Many services that were historically provided in the hospital are now routinely done in a skilled nursing facility, an outpatient facility, or the patient's home. The ratio of nurses to non-nurses providing direct nursing care has also decreased in recent years. Some of this reduction is due to hospitals replacing portions of their nursing staff with UAP as a cost-containment measure. Another factor is increased demand for nurses to work in new roles; for example, nurses may leave the bedside to provide utilization and case management services for cost-containment companies. These staff reductions have left some nurses feeling disillusioned and doubtful of their ability to provide quality healthcare, prompting them to leave the profession altogether.

Ending the cycle of nursing shortages will require adjustments in the approaches used by employers and nurses alike. New opportunities and new roles for nurses may attract more people into the profession. However, as RNs increasingly perform more highly valued functions, administrators in healthcare organizations will need to respect and compensate them accordingly.

Cost-conscious Nursing Practice

All nurses must understand the costs associated with healthcare and the ways in which these costs impact nursing practice. Because the nursing staff is the largest professional group in a hospital, it is the most expensive. However, the nursing staff does not produce revenue, because nursing services are included as part of patients' room and board charges. As a result, it is incumbent on nurse managers to be mindful of employment and nonsalary expenses and to engage their staff in looking for ways to minimize expenditures at the unit level without negatively impacting patient care (Sherman, 2012a).

This level of financial accountability is relatively new to the nursing profession and comes at a time when nursing must compete for limited resources with other departments in the healthcare organization. Consider the following: Whether nurses work in a hospital, a school, home healthcare, or another setting, they are increasingly required to participate in strategies to make care more cost effective. Initially, this may sound intimidating. However, it is critical to understand that many evidence-based nursing interventions that nurses perform daily contribute to the goal of better cost containment. For example, hand washing to reduce the risk of healthcare-associated infections reduces costs, because these infections increase expenses for both individual patients and the healthcare setting. Similarly, nursing efforts to promote safety and improve quality also promote cost-conscious nursing practice.

Although cost containment is an essential component of nursing practice, it does not negate the essential roles of nursing. Nurses in all settings must continue to advocate for care that meets the standards of best practice while trying to find new ways to contain costs.

REVIEW Cost-Effective Care

RELATE Link the Concepts and Exemplars

Linking the exemplar of cost-effective care with the concept of health, wellness, and illness:

1. Explain how health promotion activities reduce the cost of care.
2. You are caring for an adolescent patient who admits to smoking "a couple" of cigarettes per week. What impact would helping this patient quit smoking have on the lifetime cost of his healthcare?

Linking the exemplar of cost-effective care with the concept of infection:

3. How does the cost of a healthcare-acquired infection impact the cost of a patient's admission?
4. How does the cost of reducing the risk of healthcare-acquired infections compare to the cost of treating a patient who contracts a healthcare-acquired infection?

REFLECT Apply Your Knowledge

A group of nurses works on an oncology unit with 30 beds, including a 6-bed bone marrow transplant unit. Each nurse is usually assigned four or five patients, depending on acuity levels. Only nurses with advanced training are allowed to administer chemotherapy, so it is not uncommon to have one nurse assigned to be a medication nurse when many others on the same shift have not yet attended or completed the chemotherapy certification course.

1. What actions could you, as a staff nurse on this unit, take to reduce the cost of providing care to these patients?
2. The hospital is considering replacing its 10-year-old x-ray machine with a newer model that uses less radiation and is completely digital, thereby eliminating the need for film cartridges and making it easier for radiologists to read x-rays from computers in their offices or homes. However, the cost of the machine is very high. You are asked to join the committee that will make the decision about whether to purchase this equipment. What are the pros and cons of buying this new radiology equipment?

Exemplar 39.C Delegation

Exemplar Learning Outcomes

39.C Analyze delegation as it relates to managing care.

- Summarize the principles of delegation.
- Describe the benefits of delegation.
- Outline the delegation process.
- Outline factors affecting delegation.
- Describe how liability affects delegation.

Overview

Nurses play a major role in healthcare, and the United States continues to experience a nursing shortage secondary to increases in lifespan, the number of older adults requiring medical care, and the need for nursing care in nonhospital environments. As a result, registered nurses must dedicate increasingly larger portions of their time to the performance of highly skilled tasks. This often leaves them with little time to complete the less complex interventions required for attainment of successful patient outcomes. In order for such tasks to be accomplished, RNs frequently rely on the process of delegation.

In general terms, **delegation** is the transference of responsibility and authority for an activity to a competent individual. The **delegate** is the individual who assumes responsibility for the actual performance of the task or procedure. The **delegator** is the individual who assigns the task and retains accountability for the outcome. Delegation is a tool that allows the delegator to devote more time to tasks that cannot be delegated. It also enhances the skills and abilities of the delegate, which builds self-esteem, promotes morale, and enhances teamwork and attainment of the organization's goals.

Within the field of nursing, delegation refers to indirect care, meaning the intended outcome is achieved through the work of someone supervised by the nurse. It involves defining the task, determining who can perform the task, describing the expectation, seeking agreement, monitoring performance, and providing feedback to the delegate regarding performance.

Delegation is often confused with work allocation or assignment. Although the two concepts are related, they are not the same. **Assignment** refers to a skill or task that is a fundamental part of an individual's job that the individual is expected to accomplish on a regular basis (NCSBN, 2016). Asking an individual to perform a task that is a part of her regular responsibilities and job description is not delegating. In *delegation*, the nurse asks another individual to perform a task or skill that is not part of the individual's regular assigned work. In *delegating*, the nurse transfers the *responsibility* for completing the task to the delegate, but not the *accountability* for the task. Accountability remains with the nurse (NCSBN, 2016). Delegation is not easy. Complications may arise due to a number of factors, including variations in titles and

terminology, lack of training, issues of accountability and responsibility, and the nurse's discomfort with the delegation process. Still, today's emphasis on "doing more with less" means it is more critical than ever before that nurses master the skill of delegation. Once nurses learn how to delegate, they extend their ability to accomplish more by using others' help. Guidelines for successful delegation are listed in **Box 39-1** and described in detail throughout this exemplar.

Principles of Delegation

Registered nurses increasingly delegate components of nursing care to other healthcare workers, including fellow RNs, licensed practical nurses (LPNs), licensed vocational nurses (LVNs), and UAP. An RN who delegates a task to another healthcare worker is accountable for selecting an appropriately skilled caregiver and for continually evaluating the care provided to the patient by that caregiver.

Delegating to Other Nurses

Registered nurses frequently delegate tasks to other RNs. For example, a charge nurse is engaging in delegation when she makes assignments for a shift. A nurse may also opt to delegate certain care activities for a patient to another nurse, as long as the second nurse is free and can accept the additional responsibility. For instance, an RN may assign a float RN to an unstable patient with a high temperature and high

Box 39-1

Guidelines for Successful Delegation

1. Follow your state's nurse practice act and your facility's policies and procedures when delegating.
2. Delegate only tasks for which you have both accountability and responsibility.
3. Follow state regulations, job descriptions, and agency policies when delegating.
4. Follow the delegation process and key behaviors for delegating.
5. Only accept delegation when you have a clear understanding of the task, time frame, reporting requirements, and other expectations.
6. Confront your fears about delegation; recognize which fears are realistic and which are not.

blood pressure. Caring for an unstable patient is within the RN scope of practice, so the RN who accepts the assignment will be responsible for completing the patient's care safely, ethically, and completely.

In addition, it may be appropriate for an RN to delegate specific interventions to an LPN or LVN. In these cases, the RN remains responsible for ensuring that the LPN or LVN completes the interventions both correctly and appropriately.

When delegating to other nurses of any type, the RN must use critical thinking and professional judgment. He or she must also follow the widely accepted *Five Rights of Delegation*:

1. **Right task:** The delegator must ensure that the task is one that can be delegated according to the agency's policies and procedures and is appropriate for the specific patient.
2. **Right circumstances:** The delegator must determine that the task addresses the patient's needs and contributes to a desired outcome, and that adequate supervision is available.
3. **Right person:** The delegator must assign the task to a delegate who has the necessary skills and experience. Moreover, the task must be within that individual's scope of practice.
4. **Right direction:** The delegator must provide a clear, concise description of the task, along with its objectives, limits, and expectations. This material may be communicated orally or in written format. The delegator must also verify that the delegate understands the information that has been communicated.
5. **Right supervision:** The delegator must monitor and evaluate the delegate's performance. This includes providing feedback and intervening if necessary (ANA & National Council of State Boards of Nursing [NCSBN], 2006; Yoost & Crawford, 2016).

Delegating to Unlicensed Assistive Personnel

UAP, who function as "nurse extenders," are identified by a variety of titles, including certified nursing aides/assistants (CNAs), home health aides (HHAs), medical technicians, orderlies, and surgical technicians. Each category and the individuals within it have diverse levels of training and experience. Even though UAP lack licensure, nurses may delegate to them as appropriate because they are employees of the healthcare provider. (Conversely, nurses may not delegate to family members or friends of patients even if these individuals provide personal care to the patients, because these individuals do not work for the healthcare provider.)

It is not possible to generate an exhaustive list of exactly which actions are acceptable for delegation to UAP. Remember, each state's nurse practice act defines what acts may or may not be delegated to UAP within that state. Still, some general examples of tasks that may and may not be delegated are provided in **Box 39-2** >>.

SAFETY ALERT Care of unstable patients should *never* be delegated to an LPN, LVN, or UAP. If an RN must delegate all or part of the care of an unstable patient, these tasks must be delegated to another RN as appropriate.

Box 39-2

Examples of Tasks That May and May Not Be Delegated to UAP

TASKS THAT MAY BE DELEGATED TO UAP

- Taking vital signs
- Measuring and recording intake and output (I/O)
- Patient transfers and ambulation
- Postmortem care
- Bathing
- Feeding
- Gastrostomy feedings in established systems
- Attending to safety
- Weighing
- Suctioning chronic tracheostomies

TASKS THAT MAY NOT BE DELEGATED TO UAP

- Assessment
- Interpreting data
- Making a nursing diagnosis
- Creating a nursing care plan
- Evaluating care effectiveness
- Care of invasive lines
- Administering parenteral medications
- Inserting nasogastric (NG) tubes
- Patient education
- Performing triage
- Giving telephone advice

Principles guiding the nurse's decision to delegate help ensure the safety and quality of outcomes. These principles include the Five Rights of Delegation, along with those listed in **Box 39-3** >>. Note that even if a task is one that may be delegated legally, the individual nurse must still determine whether the task can be delegated to a particular UAP for a specific patient. Note also that UAP may not delegate tasks to another person.

Once a nurse has made the decision to delegate, he or she must communicate clearly to the UAP. The nurse must also verify that the UAP understands:

- The specific tasks to be done for each patient;
- When each task is to be done;
- The expected outcomes for each task, including parameters outside of which the unlicensed person must immediately report to the nurse (and any action that must urgently be taken);
- Who is available to serve as a resource if needed; and
- When and in what format (written or verbal) a task report will be completed.

As noted in **Box 39-3**, a specific task that can be delegated to one UAP may be inappropriate for a different UAP, depending on each person's experience, training, and individual skill set. Also, a task that is appropriate for a UAP to perform with one patient may be inappropriate with a different patient, or even with the same patient under altered circumstances. For example, taking routine vital signs may be delegated to the UAP for a patient who is in stable condition, but it would not be delegated for the same patient if he became unstable.

Box 39–3**Principles Used by the Nurse to Determine Delegation to Unlicensed Assistive Personnel**

1. The nurse must assess the individual patient before delegating tasks.
2. The patient must be medically stable or in a chronic condition and not fragile.
3. The task must be considered routine for this patient.
4. The task must not require a substantial amount of scientific knowledge or technical skill.
5. The task must be considered safe for this patient.
6. The task must have a predictable outcome.
7. The nurse must know and understand the agency's procedures and policies about delegation.
8. The nurse must know the scope of practice and the customary knowledge, skills, and job description for each discipline represented on the healthcare team.
9. The nurse must be aware of individual variations in work abilities and training. Each individual UAP has different experiences and may or may not be capable of performing the task to be delegated.
10. The nurse, when unsure about a UAP's ability to perform a task, must observe while the UAP performs the task or must demonstrate the task to the UAP and get a return demonstration before allowing the UAP to perform it independently.
11. The nurse must clarify reporting expectations to ensure the task is accomplished.
12. The nurse must create an atmosphere that fosters communication, teaching, and learning. For example, the nurse should encourage the UAP to ask questions, listen carefully to concerns, and make use of every opportunity to teach.

Certain tasks should never be delegated by the RN. For example, discipline of other employees, highly technical tasks, and complex patient care tasks that require specific levels of licensure, certification, or training should not be delegated. Also, any situation that involves confidentiality or controversy should not be delegated to others.

SAFETY ALERT Each healthcare provider, licensed or unlicensed, is responsible for his or her own actions. Anyone who feels unqualified to perform a delegated task must decline to perform it until he or she receives appropriate training and is assessed for competency.

Delegation Versus Dumping

Nurses should delegate because it allows them to make better use of their time. They should not delegate in order to dump an undesirable task on someone else or to reward a productive employee with more work. Sometimes, a nurse may fear that he is “dumping” on another staff member by delegating routine care; in such cases, however, the nurse needs to maintain perspective on what tasks he can complete in a timely fashion and what tasks could be performed effectively by the delegate. Delegation should always be practiced in a way that provides the greatest benefit to the patient, makes the best use of the time of all staff members, and provides delegates with opportunities for growth.

Benefits of Delegation

The proper delegation of duties can benefit the nurse, the delegate, the manager, and the organization.

Benefits to the Nurse

By delegating some tasks to UAP, nurses are able to devote more time to those tasks that cannot be delegated, such as complex patient care. For example, a nurse has three central line dressing changes and two patients who require daily weights to be completed before the shift ends in 1 hour. The nurse may delegate the task of obtaining the patients' daily weights to a UAP and complete the central line dressing changes herself. In this example delegation improves patient care in that all the necessary tasks are done but the nurse is not rushed to complete more complex tasks. By alleviating task overload, delegation also increases nurses' job satisfaction and improves an organization's employee retention rate.

Benefits to the Delegate

Delegation allows delegates to gain new skills and abilities that can help them advance within a given organization or in their overall careers. In addition, delegation often brings with it trust and support, thereby helping build the self-esteem and confidence of the delegate. Subsequently, job satisfaction and motivation are enhanced as individuals feel stimulated by new challenges, morale improves, and a sense of pride and belonging develops, as does greater awareness of responsibility. Individuals feel more appreciated and learn to appreciate the roles and responsibilities of others, increasing cooperation and enhancing teamwork. Most delegates also feel a strong sense of internal satisfaction from knowing that their contributions assisted in the achievement of desired patient outcomes.

Benefits to the Manager

Delegation yields several benefits for the nurse manager. First, if nurses are delegating appropriately to UAP, the manager's unit will function better. Also, managers who themselves appropriately delegate tasks to staff members are able to devote more time to management functions that cannot be delegated. With the additional time gained through delegation, these managers have increased opportunity to develop new skills and abilities that facilitate career advancement.

Benefits to the Organization

As teamwork improves, the organization benefits by achieving its goals more efficiently. As efficiency increases, the quality of care and patient satisfaction improve. Employee overtime and absences decrease. Productivity increases, and the organization's financial position may improve.

The Delegation Process

Nurses may delegate only those tasks for which they have responsibility and authority. These include routine tasks, tasks for which the nurse does not have time, and tasks that have moved down in priority. Whenever a nurse opts to transfer authority for one or more of these tasks, he or she must engage in the delegation process. According to the

NCSBN (2012), this process consists of four distinct steps that should be followed for every situation involving delegation:

1. Assessment and planning
2. Communication
3. Surveillance and supervision
4. Evaluation and feedback

Each of these steps is described in detail in the following sections.

Assessment and Planning

Assessment and planning combine to form the critical first step in the delegation process. Prior to the actual delegation of any task, the nurse needs to consider the following questions:

- Is the task within the scope of the nurse's practice?
- Have the patient's needs been assessed?
- Is the nurse competent to make delegation decisions?
- Is the task consistent with the recommended criteria for delegation? (See Box 39–3 for a list of these criteria.)
- Does the delegate have the appropriate training, skills, and knowledge to perform the task safely, using current standards of practice?
- Are organizational policies, procedures, or protocols available for the task?
- Is adequate supervision available?

If the answer to each of these questions is “yes,” then the nurse may continue to the next step in the delegation process (NCSBN, 2012).

Communication

The second step in delegation is to communicate with the delegate regarding expectations for the task. Appropriate communication goes both ways: from the delegator to the delegate, and from the delegate to the delegator. Specifically, the delegator must allow enough time to clearly describe the task and expectations for completing it, answer the delegate's questions, address any situations that must be reported to the delegate, and inform the delegate of the nurse's own availability in the event the delegate has further questions or needs assistance. Some behaviors that can assist in the accomplishment of these tasks are described in **Box 39–4** ». The delegator must also consider any cultural factors that might affect the delegation process, as described in the Focus on Diversity and Culture feature.

The delegate also has certain responsibilities. In particular, the delegate needs to communicate understanding of the task, inform the delegator if she has never performed the task before, request training if needed, and describe what communication and action should be undertaken in an emergency situation. Both the delegator and the delegate should also have a clear understanding of how the delegated task will be documented in the nursing record (NCSBN, 2016).

Surveillance and Supervision

Surveillance is necessary to validate that the delegated task or function is being delivered in compliance with agency

Box 39–4

Key Behaviors When Delegating Tasks

When delegating a task to another staff member, the nurse should:

- Describe the task using “I” statements (e.g., “I would like ...”) and appropriate nonverbal behaviors (e.g., open body language, face-to-face positioning, and eye contact). The delegate needs to know what is expected, when the task should be completed, and also where and how (if appropriate). More experienced delegates may be able to define for themselves the where and how. The nurse must decide whether written reports are necessary or if brief oral reports are sufficient. If written reports are required, the nurse should indicate whether tables, charts, or other graphics are necessary. The nurse should be specific about reporting times. In patient care tasks, it is also important to determine who has responsibility and authority to chart certain tasks: UAP can enter vital signs, but if they observe changes in patient status, the RN must investigate and chart his or her assessment.
- Describe the importance of the task to the organization, the delegator, the patient, and the delegate.
- Clearly describe the expected outcome and the timeline for completion. Here, the nurse must also establish how closely the assignment will be supervised.
- Identify any constraints on completing the task or any conditions that could change. For example, the nurse may ask an assistant to feed a patient as long as the patient is not having difficulty swallowing; should the patient begin to demonstrate dysphagia, then the nurse will take over feeding activities.
- Have the delegate repeat back the task and specific directions. The nurse should further validate the delegate's understanding of the task and its expectations by eliciting questions and providing feedback.

policies and procedures and current standards of practice. Surveillance also validates that the delegate is working within his scope of practice. The amount of supervision required depends on the nature of the task, the delegate's experience, and the patient's needs. It is critical that the delegating nurse try to find a balance between too much and too little surveillance. The delegator should remain accessible because her support will build the delegate's confidence, reassure the delegate of her interest, and negate any concerns that she is dumping undesirable tasks; however, monitoring a delegate too closely may convey distrust.

In some instances, surveillance may reveal that the delegate needs closer supervision or assistance with the delegated task. For example, the delegator may notice subtle changes in the patient's signs and symptoms or observe that the delegate is having difficulty completing a particular activity. When situations such as these occur, the delegating nurse should intervene as appropriate, whether this involves providing the delegate with further guidance in task performance or opting to reassume responsibility and personally complete the task (NCSBN, 2016).

Evaluation and Feedback

Although often overlooked, evaluation and feedback are critical final elements of the delegation process. When engaging in evaluation, the delegator must compare the

Focus on Diversity and Culture

Transcultural Delegation

Just like patients, the members of a healthcare team often come from a variety of cultural backgrounds. Therefore, the nurse must take cultural phenomena into account when delegating to other nurses and UAP. These phenomena fall into six broad categories:

- **Communication:** Different cultures interpret certain elements of verbal and nonverbal communication in different ways. These include such things as eye contact, posture, volume, gesticulation, touch, and passive versus assertive wording.
- **Space:** Staff members' cultural backgrounds often influence their preferred zone of interpersonal space. For example, people from some cultures prefer to communicate at close distance, whereas people from other cultures view physical closeness as uncomfortable, rude, or intrusive.
- **Social organization:** Cultures vary in the level of importance they place on close social relationships. Thus, depending on cultural background, some staff members may desire higher levels of social support while carrying out delegated tasks.

Sources: Based on Kelly, P., & Tazbir, J. (2014). *Essentials of nursing leadership and management* (3rd ed.). Clifton Park, NY: Delmar-Cengage Learning; Poole, V. L., Davidhizar, R. E., & Giger, J. N. (1995). Delegating to a transcultural team. *Nursing Management* 26(8), 33–34; Yoost, B. L., & Crawford, L. R. (2016). *Fundamentals of nursing: Active learning for collaborative practice*. St. Louis, MO: Elsevier.

- **Time:** A culture may be past, present, or future oriented. Staff members' orientation toward time can affect their attitudes toward such things as scheduling and short- versus long-range goals.
- **Environmental control:** Staff from cultures with an internal locus of control tend to focus on planning and acting proactively, whereas staff from cultures with an external locus of control are more likely to focus on overcoming obstacles and dealing with events as they arise.
- **Biological variations:** A person's background may influence certain physical characteristics (e.g., size, disease susceptibility), as well as his or her attitude toward particular biological conditions and variations.

Cultural variations should be considered when developing the plan for how a task will be explained, completed, reported, and evaluated. Consideration of such factors will help facilitate the best possible outcomes for patients, staff, and the healthcare organization as a whole.

delegate's performance against appropriate policies, procedures, and standards of practice. The delegator must also determine whether the delegate's actions contributed to achievement of the agreed-upon objectives. Specific questions that can help the nurse evaluate the effectiveness of delegation include the following:

- Was the delegated task performed appropriately and successfully?
- Was the desired outcome achieved in a satisfactory manner?
- Was communication between the delegator and delegate both timely and effective?
- Which aspects of the task and/or the delegation process went well? Which aspects did not proceed so smoothly?
- Did any problems arise? If so, how were they addressed?
- Could the patient's need(s) be met in a more effective way?
- Should any adjustments be made to the patient's overall plan of care in light of the delegated task or activity?

If problem areas are identified, the nurse should promptly and quietly investigate the problem and explain any concerns to the delegate. An opportunity for feedback from the delegate must be given. The nurse should then instruct the delegate on how to prevent similar problems in the future. Note, however, that giving praise and recognition for a job well done is equally important (NCSBN, 2016).

The following Clinical Example explores how a school nurse would use this overall process when delegating the task of medication administration.

Clinical Example B

Lisa Ford is a school nurse for a suburban school district. She has responsibility for three school buildings, including a middle school, a

high school, and a magnet school that offers a Spanish-English immersion program for elementary students as well as four classrooms of 4- and 5-year-old children with various special needs. Lisa's management responsibilities include providing health services for 1500 students, 80 faculty members, and 25 staff members, as well as supervising two unlicensed school health aides and three special education health aides. The logistics of managing multiple school sites means that Lisa must delegate many daily tasks, including medication administration, to the school-based health aides.

Nancy Andrews is an unlicensed health aide at the middle school. This is her first year as a health aide, and she has a limited background in healthcare. The nurse practice act in this state allows for delegation of medication administration in the school setting. Lisa is responsible for training Nancy to safely administer medication to students, documenting the training, evaluating Nancy's performance, and providing ongoing supervision. Part of Nancy's training will include a discussion of those medication-related decisions that must be made by a registered nurse.

To delegate medication administration to Nancy, Lisa must do all of the following:

- Understand the state nurse practice act and its applicability to the school setting.
- Implement school district policies related to health services and medication administration.
- Develop and implement an appropriate training program.
- Limit opportunities for error and decrease liability by ensuring that unlicensed health aides are appropriately trained to handle delegated tasks.
- Maintain documentation related to training and observation of medication administration by unlicensed staff.
- Audit medication administration records to ensure accuracy and completeness.
- Conduct several "drop-in" visits during the school year in order to track the competency of health aides.
- If necessary, report any medication errors to administration, and follow up with focused training and closer supervision.

- Provide constructive feedback and address any concerns.
- Acknowledge the effectiveness of the unlicensed health aide's efforts.

Critical Thinking Questions

1. If you were a school nurse, what would you include in your training of unlicensed health aides for medication administration?
2. Other than medication administration, what duties typically needed at a school could be delegated to the unlicensed personnel? What duties could not be delegated?
3. How would you respond if a task that you delegated to an unlicensed health aide was completed incorrectly and resulted in harm to a child?

Factors Affecting Delegation

A number of factors may affect delegation, including organizational culture, assignment patterns, and the personal qualities of the participants. Resource availability, such as having sufficient staff to whom the nurse may delegate tasks, also impacts delegation.

Assignment Patterns

Three assignment patterns affect delegation: unit-based assignment, pairing, and partnering. The unit-based approach assigns assistive personnel such as UAP to serve everyone on the unit by working from a task list. Limited planning between the RNs and support staff is a feature of unit-based assignment patterns; consequently, there is no sense of teamwork. With this type of assignment, RNs frequently ask for assistance as needed. Their requests are made in a vacuum; that is, none of the nurses are aware of the demands being placed on the UAP by others, thus placing the UAP in the position of managing conflicting requests. Not surprisingly, this approach does not lend itself to effective delegation and causes dissatisfaction among both RNs and support staff.

A more effective means of delegation is pairing, or the assignment of an RN, LPN, and/or UAP to work together as a team for a shift. Pairs are not scheduled to work together consistently; therefore, the team's composition varies from day to day. Pairs are able to plan care; team members identify priorities and plan each patient's individual outcomes for the shift. Pairing increases satisfaction among team members and facilitates delegation.

Partnering is the best assignment pattern. It is the consistent scheduling of a set team, such as an RN, LPN, and/or nursing assistant, who always work together. This consistency creates healthy interpersonal relationships and increases trust. Each partner is able to anticipate the others' needs and expectations. Partnering is the ideal approach to delegation and increases employee satisfaction and, in turn, patient satisfaction (Potter et al., 2017; Weydt, 2010).

Delegate Understanding, Acceptance, and Communication

Delegates are responsible for making sure they fully understand a task before accepting it. Before accepting the task, the delegate must evaluate whether she has the skills and abilities to complete it. If the delegate does not possess the necessary skills and abilities, she must inform the delegator. The delegate must also discuss with the delegator whether or not there is sufficient time to complete the task.

If the delegate does not have the necessary skills or abilities but the delegator is willing to train the delegate to complete the task, the delegate may accept the task provided there is time for sufficient training and questions before the task must be completed.

By accepting delegation, the delegate accepts full responsibility for the outcome of the task. Note that the delegate has the option to negotiate to perform only those parts of the task for which the delegate has been trained.

Once the delegate and delegator have agreed on the nature of the assignment and their roles and responsibilities, they should clarify the time frame and other expectations of the task as well as how the delegate is to report the outcome of the task and what kind of assistance and feedback the delegate can expect from the delegator. The delegate should keep the delegator informed of progress and report any concerns or unexpected events. Finally, the delegate should complete the assignment as agreed and report the task as completed in a timely manner. This fosters trust between delegator and delegate and builds the delegate's reputation for dependability and credibility.

Obstacles to Delegation

Delegation can yield many benefits, but it also has barriers that can potentially endanger patients and/or lead to unsuccessful outcomes. For example, when a patient does not receive ambulation because nursing staff fails to follow through on this important activity, the patient may be at increased risk for falls, pneumonia, and development of deep vein thromboses and pressure ulcers.

Some barriers to delegation are environmental, whereas others are the result of the delegator's or delegate's beliefs or inexperience, as described in the sections that follow.

A Nonsupportive Environment

Some environments simply do not support delegation. For example, the culture of an organization may, through rigid chains of command and autocratic leadership styles, restrict delegation. In this type of organizational culture, the norm is to do all work oneself because other staff members are not viewed as capable or skilled. These types of environments promote an atmosphere of distrust, as well as poor tolerance for mistakes.

A lack of resources can also inhibit delegation. For example, there may not be adequate staff to whom a nurse can delegate certain responsibilities. Consider the example of a sole RN in a skilled nursing facility. If the state's nurse practice act defines a particular task as one that only an RN can perform, then there is no one within the facility to whom the nurse can delegate that task.

Financial constraints also can interfere with delegation. For instance, if one member of a department must attend the annual conference in a nursing specialty area but the organization will pay only the manager's travel and conference expenses, then the manager cannot delegate the task of attending the conference to anyone else.

Educational resources may be another limiting factor. Others can learn how to do a task, but only if the proper equipment and a trainer are available.

Time resources can limit the ability to delegate as well. For example, suppose it is Friday, the schedule needs to be posted on Monday, and the nurse manager in charge of scheduling

must leave town because of an unexpected family emergency. If no one on staff has been trained to develop the schedule, the schedule will not be posted or will be developed by someone who has not been trained to create it, thus leaving the unit open to the many problems that can result from poor scheduling.

Delegator Insecurity

Delegators often feel insecure about delegation, because they remain accountable for the tasks involved. Some delegators see delegates as competition. In reality, the success of a delegate reflects well on the delegate and on the delegator. Some delegators fear being blamed or being liable if a delegate makes a mistake. By following the delegation process and adhering to the Five Rights of Delegation, the delegator minimizes the risks of liability and the responsibility for any mistakes shifts to the delegate.

Beyond these fears, additional barriers to delegation on the part of the delegator include inadequate organizational skills, such as poor time management, and inexperience with delegation.

An Unwilling Delegate

Inexperience and fear of failure can motivate a potential delegate to refuse a delegated task. Delegates who lack confidence or experience need a great deal of reassurance and support. Furthermore, the delegator needs to equip this type of delegate to be able to handle the task. If the delegator follows the delegation process and the five rights of delegation, then the delegate should not fail.

The delegator can help boost the delegate's confidence by building on simple tasks. The delegate also needs to be reminded that everyone was inexperienced at one time. Another common concern for many delegates is how mistakes will be handled. Thus, when describing a task, the delegator should provide clear guidelines for handling problems—guidelines that adhere to organizational policies. The delegator also needs to ensure availability for any delegate needs.

Other delegate-related barriers to successful delegation include individuals who avoid responsibility or are too dependent on others. Success breeds success; therefore, it is important to engage the delegate in a simple task that guarantees success and to recognize the delegate's accomplishment when the task is finished.

Ineffective Delegation

When the delegation process is not followed or barriers remain unresolved, delegation is often ineffective. Ineffective delegation can also result from unnecessary duplication, underdelegation, reverse delegation, and overdelegation.

Unnecessary Duplication

If staff are duplicating the work of others, related tasks may have been given to too many people. To avoid unnecessary duplication, associated tasks should be delegated to as few people as possible. This allows each delegate to complete her assignment without spending time negotiating with others about which task should be done by which person. This also simplifies reporting for both the delegate and the delegator. If multiple people are involved in the delegation, then a team meeting should be held to develop a plan of who will be performing which tasks. This will both enhance teamwork and minimize duplication.

To further prevent duplication of work, the nurse should consider the following questions:

- How often do staff members duplicate an activity that someone else has recently performed?
- Why does this duplication occur, and is it necessary?
- What needs to be done to prevent this duplication?

Underdelegation

Underdelegation is a situation in which efforts at delegation fail because of one or more of the following factors:

- The delegator fails to transfer full authority to the delegate.
- The delegator takes back responsibility for certain aspects of a delegated task.
- The delegator fails to appropriately equip and direct the delegate.

As a result, the delegate is unable to complete the task, and the delegator must resume responsibility for its completion. The following Clinical Example describes a scenario in which underdelegation has occurred.

Clinical Example C

After completing Nancy's training (see the prior Clinical Example), Lisa gives Nancy the authority to begin administering medications to the students in her school. During the first week of classes, Nancy tries to "speed up" the medication administration process by setting out all of the noon medications in individual, unlabeled cups for the students. The cups are rearranged by students trying to find their medications, and Nancy cannot identify which meds belong to which students. Lisa is called back to the school to administer the correct medications, students are late to class, and Nancy is frustrated that she couldn't handle the task.

Critical Thinking Questions

1. Which of the four steps of the delegation process did Lisa fail to follow?
2. Which step or steps did Nancy fail to follow?
3. What should Lisa do to prevent this situation from happening again?

Reverse Delegation

In **reverse delegation**, someone with a lower rank delegates a task to someone with more authority. For example, say a nurse practitioner in a burn unit arrives on the unit to find several patients whose dressing changes have not been completed due to a code situation earlier in the morning. An LPN asks the nurse practitioner to complete a few dressing changes to help the staff before physician rounds begin. If the nurse practitioner agrees to the LPN's request, then reverse delegation has taken place.

Overdelegation

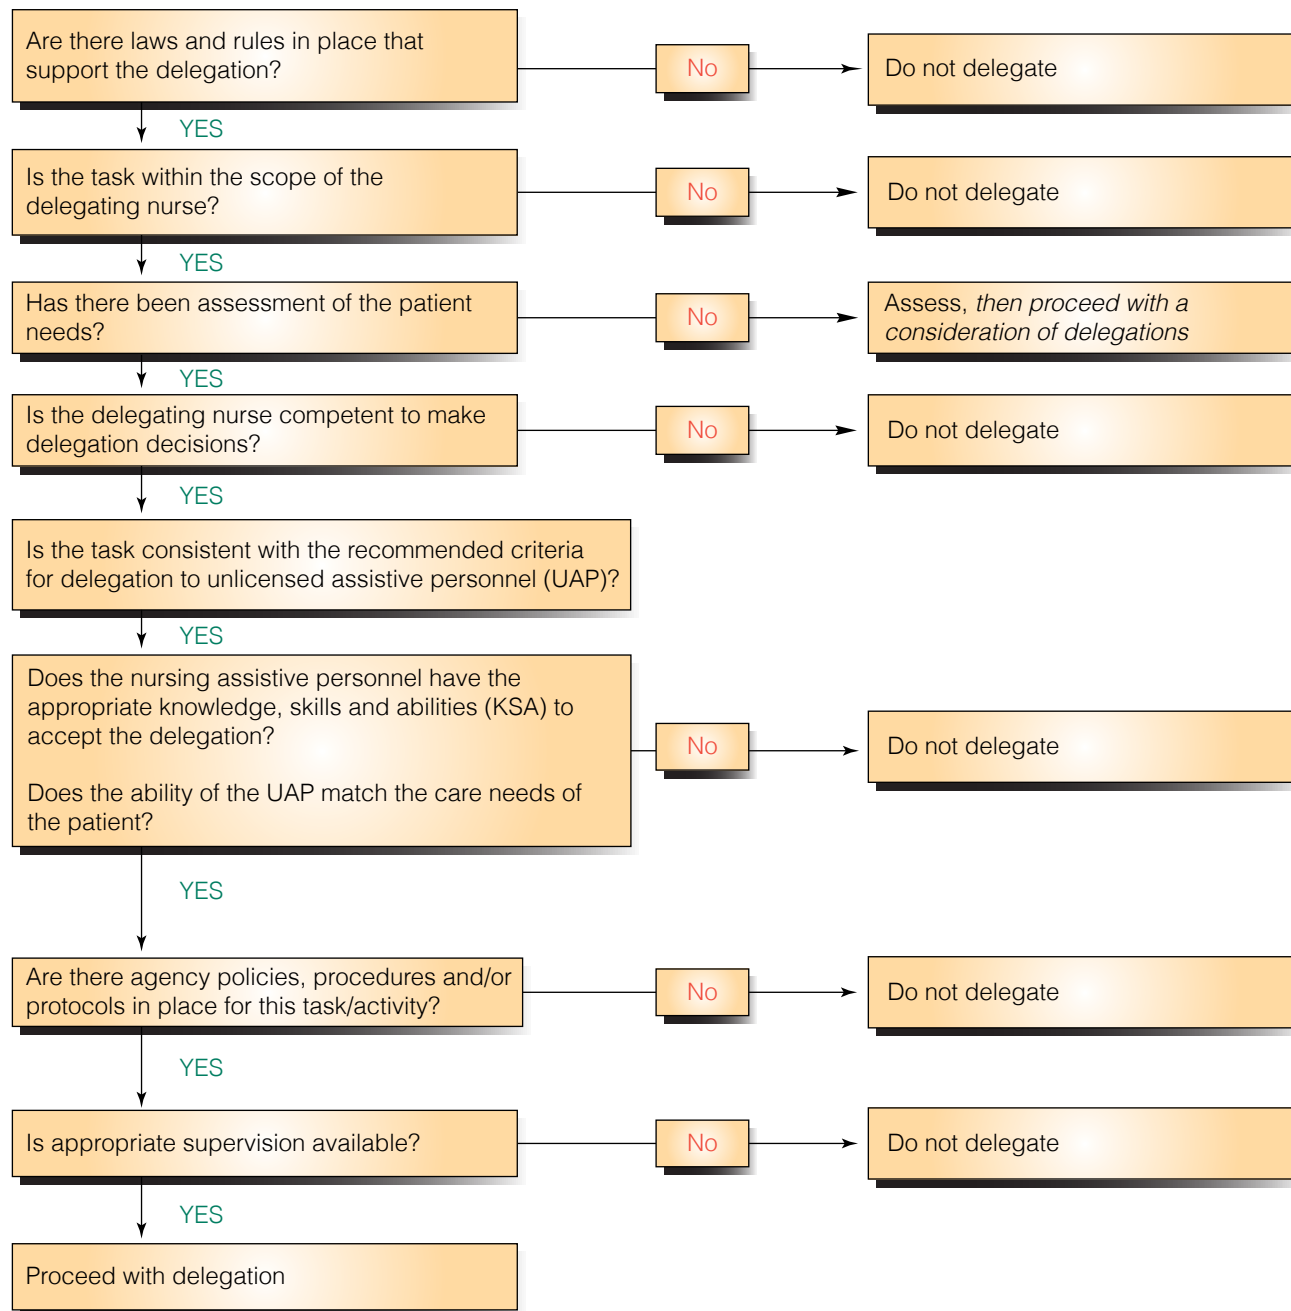

Overdelegation occurs when the delegator loses control of a situation by providing the delegate with too much authority or too much responsibility. This places the delegator in a risky position, increasing the potential for liability.

Liability and Delegation

Fear of liability often keeps nurses from delegating. State nurse practice acts determine the legal parameters for practice, professional associations set practice standards, and

organizational policy and job descriptions define delegation appropriate to the specific work setting. Adherence to these rules should protect nurses from liability, but several additional guidelines can provide extra peace of mind when delegating. Perhaps the most useful guidelines for nurses to remember are the Five Rights of Delegation, as identified by the ANA and NCSBN in 2005 and described earlier in this exemplar. In addition, the ANA and NCSBN (2006) have issued a joint statement on delegation to explain both the profession's practice guidelines and the legal requirements for delegation. **Figure 39-4** » shows a decision tree for delegation from the joint statement.

One situation that may present a challenge is when staff members receive written or verbal orders from a physician's office nurse. The same legal guidelines for the nurse giving the orders apply to the staff receiving them. If the nurse calling from the physician's office has a license that allows prescribing privileges, such as a nurse practitioner license, then the staff can accept appropriate orders from the physician's nurse. Otherwise, the orders must also be verified by the prescribing physician. The staff members put their own licenses in jeopardy if they do not obtain verification from the physician when necessary.

REVIEW Delegation

RELATE Link the Concepts and Exemplars

You are an RN working on a medical unit with two other RNs, an LPN, and two UAP. You receive a call informing you that two patients (both of whom are assigned to your care) must be transferred to another unit in order to make room for two patients who are to be admitted as soon as the rooms are ready.

Linking the exemplar of delegation with the concept of collaboration:

1. You delegate collection of one patient's possessions in preparation for transfer to one of the UAP, who says, "Why are you dumping this work on me? You do it." How would you manage this conflict?
2. The LPN working on the unit is a new graduate and has been employed for only 4 weeks. How would you collaborate with this nurse when delegating tasks for completion?

Linking the exemplar of delegation with the concept of teaching and learning:

3. How can you facilitate the new LPN's education in performing tasks that are commonly delegated?
4. How would you evaluate the LPN's learning related to delegated tasks?

REFER Go to Pearson MyLab Nursing and eText

- Additional review materials

REFLECT Apply Your Knowledge

You are working the night shift on a medical unit and have been assigned charge nurse responsibilities. You are working with four RNs, one LPN, and two UAP. A patient becomes pulseless and is not breathing, and the nurse assigned to the patient's care calls a code. The nurse is occupied at this patient's bedside for 1.5 hours until the resuscitation effort is completed and the patient is transferred to the intensive care unit. This nurse also has four other assigned patients. In addition to the nurse assigned to care for the patient requiring resuscitation, two of the other nurses working on your unit are assisting in the code.

1. What tasks could you delegate to the UAP?
2. How will you maintain the safety of the other patients on your unit while the three nurses are occupied with the patient who requires resuscitation?
3. How might effective delegation to other team members contribute to care of the patients on the unit?

Overview

Although leadership and management are important concepts in nursing, some nurses struggle to understand the difference between leaders and managers. In broad terms, **leaders** are individuals who use interpersonal skills to influence others to accomplish specific goals. Leaders tend to be productive and persuasive and exhibit initiative and confidence, and they play a significant role in organizational success. Leadership may be formal or informal. A **formal leader**

is one who is selected by an organization and given official authority to make decisions and to act. An **informal leader** is not officially appointed to direct the activities of others but, because of a combination of talent, ability, seniority, or age, is recognized by the group as a leader. Within the healthcare environment, formal and informal nurse leaders alike often participate in and guide teams that assess effectiveness of care, implement evidence-based practice, and construct process improvement strategies.

In contrast to leadership, management is always formal. **Managers** are individuals who hold an official position within an organization and are essential to the organization's success. Managers go by a variety of titles, including (but not limited to) *manager, director, supervisor, and administrator*. Nurse managers may manage units, departments, or entire facilities. On any given day, they must balance the needs of patients, professional staff, nonprofessional staff, contractors, the organization, and themselves. In order to meet the needs of these groups, nurse managers require a body of knowledge and skills distinct from those used in general nursing practice. Unfortunately, a gap often exists between what managers know and what managers need to know. New managers tend to apply skills learned through experiences with former supervisors rather than through formal management training. Increasing the number of nurses who hold BSN and MSN degrees could help close this gap.

All nurses manage and lead—at least in a practical sense. Whether through example, delegation, or the authority of their position, they formally and informally direct the work of professional and nonprofessional staff in order to achieve desired outcomes in patient care. As a result, all nurses should seek to build their leadership and management skills, no matter their current position or career aspirations.

Leadership Theories

Because leadership is a learned process, being an effective leader requires an understanding of the needs, goals, and rewards that motivate people. It also requires knowledge of leadership skills and of the group's activities as well as possession of the interpersonal skills necessary to influence others.

When learning leadership skills, it is helpful to be familiar with leadership theories. These theories describe the traits, behaviors, motivations, and choices leaders use to influence others. Classic leadership theories focus on what leaders are (trait theories), what leaders do (behavioral theories), and how leaders adapt their style according to the situation (contingency theories). Contemporary theories look at the emotions and relationships involved in leadership, as well as the importance of empowerment and shared responsibility. In practice, good leaders combine components of classical and contemporary theories into their daily interactions with others, and no single theory or type of theory adequately describes all of the components of leadership.

Classic Leadership Theories

Most classic leadership theories are classified as trait based or behavior based. Trait theories of leadership hold that successful leaders possess specific traits and abilities, including good judgment, decisiveness, knowledge, adaptability, integrity, tact, self-confidence, and cooperativeness. These theories have traditionally posited that leader traits and abilities are something an individual is born with, not something that is learned or acquired. In contrast, behavioral theorists believe that through education, training, and life experiences, leaders develop a particular leadership style. According to this point of view, an individual's leadership style can be described as autocratic, democratic, laissez-faire, or bureaucratic.

An **autocratic leader**, also called an **authoritarian leader**, makes decisions for the group based on the belief that individuals are externally motivated (in other words, they desire rewards from others) and are incapable of independent decision making. Similar to a dictator, the autocratic leader determines policies and gives orders and directions to the group. Under this leadership style, the group may feel secure because procedures are well defined and activities are predictable. Productivity may also be high. Under the autocratic leader, however, the group's needs for creativity, autonomy, and self-motivation are not met, and there is little or no openness and trust between the leader and group members. Although group members are often dissatisfied with this leadership style, there are times when an autocratic style is the most effective. For instance, when urgent decisions must be made (e.g., in the case of a cardiac arrest, unit fire, or terrorist attack), one individual must assume responsibility without being challenged by other team members. Similarly, when group members are unable or do not wish to participate in making a decision, the authoritarian style solves the problem and enables the group to move on. This style can also be effective when a project must be completed quickly and efficiently.

Unlike an autocratic leader, a **democratic leader** (also called a **participative** or **consultative leader**) encourages group discussion and decision making. This type of leader acts as a catalyst or facilitator, actively guiding the group toward its goals. Group productivity and satisfaction are high as group members contribute to the work effort. The democratic leader assumes that individuals are internally motivated (in other words, they desire personal satisfaction), are capable of making decisions, and value independence. Democratic leaders typically provide constructive feedback, offer information, make suggestions, and ask questions to gain information or help group members grow. This leadership style demands that the leader have faith in the group's ability to accomplish its goals. Although democratic leadership has been shown to be less efficient and more cumbersome than authoritarian leadership, it allows self-motivation and creativity among group members. It also calls for a great deal of cooperation and coordination. This leadership style can be extremely effective in the health-care setting.

The **laissez-faire leader** recognizes the group's need for autonomy and self-regulation. This leader takes a hands-off approach, being less directive and more permissive than other types of leaders. The laissez-faire leader assumes that the group is internally motivated. However, under a laissez-faire leader, group members may work at cross purposes because of a lack of cooperation and coordination. A laissez-faire style is most effective for groups whose members have both personal and professional maturity, so that once the group has made a decision, the members are committed to it and have the required expertise to implement it. Individual group members then perform tasks in their area of expertise while the leader acts as a resource person.

Finally, the **bureaucratic leader** relies on the organization's rules, policies, and procedures to direct the group's work efforts. Group members are usually dissatisfied with a bureaucratic leader's inflexibility and impersonal relations with them.

In addition to trait and behavioral theories, contingency theories account for a third category of classic leadership theories. These theories propose yet another type of leader: the **situational leader**, who adapts his or her leadership style to the situation. According to contingency theorists, a situational leader is flexible in task and relationship behaviors, considers staff members' abilities, knows the nature of the task to be done, and is sensitive to the context or environment in which the task takes place. A task-oriented situational leader focuses on activities that encourage group productivity and getting necessary work done. A relationship-oriented situational leader focuses on interpersonal relationships and meeting group members' needs. Regardless of orientation, situational leaders adapt their leadership style to the readiness and willingness of the individual or group to perform the assigned task.

Contemporary Leadership Theories

Contemporary leadership theories break leaders into three groups: charismatic leaders, transactional leaders, and transformational leaders. They also consider the ideas of shared leadership, shared governance, and servant leadership.

A **charismatic leader** is rare and is characterized by the ability to cultivate an emotional relationship with group members. The charming personality of the leader evokes strong feelings of commitment in the group, and these feelings extend to both the leader and the leader's cause and beliefs. The followers of a charismatic leader often overcome extreme hardship to achieve the group's goals because of their faith in the leader.

The **transactional leader** has a relationship with group members based on an exchange for some resource valued by the members. These incentives are used to promote loyalty and performance. For example, in order to ensure adequate staffing on the night shift, a nurse manager might entice a staff nurse to work the night shift in exchange for a weekend shift off. The transactional leader focuses on the day-to-day tasks of achieving organizational goals and understanding and meeting the needs of the group.

In contrast, a **transformational leader** fosters creativity, risk taking, commitment, and collaboration by empowering the group to share in the organization's vision. The leader inspires others with a clear, attractive, and attainable goal and enlists them in reaching it. Through shared values, honesty, trust, and continual learning, the transformational leader empowers the group. This empowerment facilitates independence, individual growth, and change. Given these characteristics, it is not surprising that the Institute of Medicine (IOM) recommends use of a transformational model of nursing leadership. According to the IOM (2010), this model empowers nurses to lead efforts for change in a complex healthcare environment. For more information on the traits required by transformational nursing leaders, see **Box 39-5** >>.

Shared leadership is centered around the idea that a professional workforce is made up of many leaders. No one individual is believed to have knowledge or ability beyond that of other members of the work group. Appropriate leadership is thought to emerge in relation to the challenges that confront the work group. Examples of shared leadership in nursing include self-directed work teams, co-leadership, and shared governance. As described in the concept of

Box 39-5

Transformational Leadership in Nursing

Transformational leadership in nursing requires effective leaders who are compassionate and dedicated to their team, their patients, and the nursing profession. Research indicates that these leaders possess certain personal characteristics. Most notably, they are:

- Committed to excellence
- Trustworthy
- Accessible
- Empathetic and caring
- Committed to staff development
- Optimistic and positive
- Knowledgeable about nursing and leadership
- Aware of their own strengths and weaknesses
- Committed to lifelong learning

Evidence also reveals that effective nursing leaders possess a passion for nursing; good communication and crisis management skills; a clear vision and strategic focus for their team; a sense of responsibility to staff and patients; a strong moral compass; and high levels of common sense. Effective nursing leaders frequently call on these traits and skills as they strive to respect patients and team members, mentor staff, direct patient care, and build personal connections with their fellow employees.

Sources: Based on Anonson, J., Walker, M. E., Arries, E., Maposa, S., Telford, P., & Berry, L. (2014). Qualities of exemplary nurse leaders: Perspectives of frontline nurses. *Journal of Nursing Management*, 22(1), 127–136. doi:10.1111/jonm.12092; Guyton, N. (2012). Nine principles of successful nursing leadership. *American Nurse Today*, 7(8). Retrieved from <https://americannursetoday.com/nine-principles-of-successful-nursing-leadership/>; Sherman, R. (2012b). What followers want in their nurse leaders. *American Nurse Today*, 7(9). Retrieved from http://www.medscape.com/viewarticle/771912_2.

Managing Care, shared governance is a method that aims to distribute decision making among a group of people.

Finally, **servant leadership** is rooted in the belief that the most effective leaders are those who are motivated primarily by a desire to serve, rather than a desire to lead. According to this theory, by placing others' needs before their own, servant leaders inspire their followers to grow and become more self-directed. As a result of this personal growth, the followers themselves feel more empowered to act in the best interests of both the organization and the people around them. Servant leadership's emphasis on service, caring, and compassion make it an especially good fit for the healthcare environment and nursing in particular. Use of this leadership model cultivates not only stronger staff relationships, but also stronger nurse–patient relationships. Furthermore, effective servant leadership enhances the quality of care, promotes nurses' personal and professional development, increases nurses' job satisfaction, and helps empower nurses and patients alike to achieve better health outcomes (Huber, 2014; McCann, Graves, & Cox, 2014; Stanley, 2017).

No matter the theory or theories used, an effective leader must have *vision*—or a mental image of a possible and desirable future state—and must be able to transform this vision into a realistic future goal that others can understand. In doing this, leaders often rely on **influence**, or an informal strategy for gaining cooperation through persuasion and

communication rather than authority. As part of influencing others, leaders act as positive role models, demonstrating caring toward coworkers and patients. Leadership may also be humanistic, or characterized by an emphasis on individuals' dignity and worth. As this suggests, being a good leader takes thought, care, insight, commitment, and energy.

Clinical Example D

Lauren Chavoen works in a hospital where senior management believes it is essential to engage nursing staff in planning, implementing, and evaluating patient care policies. Lauren realizes that she is not yet ready to assume a management position, but she understands that senior management's beliefs offer her a chance to develop some leadership and management skills through participation in policy development.

Critical Thinking Questions

1. How should Lauren convince her manager that her participation would benefit not only herself but her unit also?
2. Evaluate what skills Lauren will need to be successful on the committee she joins.

Management Functions

Management and leadership are closely tied to each other, although the functions associated with management tend to be more clearly defined than those associated with leadership. These functions were first described by French industrialist Henri Fayol in 1916 as *planning*, *organizing*, *directing*, and *controlling*. Though a century has passed, the fundamental functions identified by Fayol remain relevant for nurse managers today.

Planning

Planning is a four-stage process that involves the following:

1. Establishing objectives (goals).
2. Evaluating the present situation and predicting future trends and events.
3. Formulating a planning statement (means).
4. Converting the plan into an action statement.

Planning is important on both organizational and personal levels. It is an individual or group process that addresses the questions of what, why, where, when, how, and by whom. Decision making and problem solving are inherent in planning.

Organization-level plans, such as plans for organizational structure and staffing or operational budgets, evolve from the mission, philosophy, and goals of the organization. Within larger organizational plans, the nurse manager develops specific goals and objectives for his or her area of responsibility.

Planning is either strategic or contingent. A **strategic plan** defines the overall purpose and desired results of an organization and describes how those results will be achieved. A **contingency plan**, on the other hand, helps an organization prepare for unplanned events and determine in advance how it will respond to them. The strategic planning process uses continual assessment, planning, and evaluation to guide the future. Its purpose is creating an image of the desired future and designing ways to make that future a reality. For example, a nurse manager might be charged

with developing a plan to add a time-saving device to commonly used equipment. The manager must present the plan persuasively and develop operational strategies for implementation, such as acquiring the device and training staff in its use.

The contingency planning process requires the nurse manager to identify and manage unplanned and unexpected events that interfere with the quality of care and service delivered to patients. Contingency planning may be done *reactively*, in response to a crisis, or *proactively*, in anticipation of problems or in response to opportunities. Proactive planning is always preferable. Examples of problems that require contingency planning include the following:

- Two registered nurses call in sick for the 12-hour night shift.
- The manager of a specialty unit receives a call for an admission, but all of the unit's beds are taken.
- The manager of a pediatric oncology clinic discovers that a patient's sibling exposed several other immunocompromised patients to chickenpox.

Organizing

Organizing is the process of coordinating the work to be done. Formally, it involves identifying the work of the organization, dividing the labor, developing the chain of command, and assigning authority. Organizing is an ongoing process that systematically reviews the use of human and material resources. In healthcare, the mission, formal organizational structure, delivery systems, job descriptions, skill mix, and staffing patterns form the basis for organizing.

Directing

Directing is the process of getting the organization's work done. A manager's ability to direct is related to his or her power, authority, and leadership style. The manager's communication abilities, motivational techniques, and delegation skills are also important.

In today's healthcare organizations, professional staff members are autonomous, requiring guidance rather than direction. Thus, a manager is more likely to sell an idea, proposal, or new project to staff members than to tell them what to do. The manager coaches and counsels to achieve the organization's objectives. In fact, it may be the nurse who assumes the traditional directing role when working with unlicensed personnel.

Controlling

Controlling involves comparing actual results with projected results, similar to the evaluation step in the nursing process. Controlling includes establishing performance standards; determining how to measure performance; and creating the tools that permit consistent measurement, performance evaluation, and provision of feedback. The efficient manager constantly attempts to improve productivity by incorporating techniques of quality management, evaluating outcomes and performance, and instituting change as necessary.

Today, managers share many control functions with staff. In organizations that use a formal quality improvement process, such as continuous quality improvement (CQI), staff

members participate in and lead the CQI teams. Organizations are also increasingly using peer review as a means of controlling the quality of care and service. Peer review is the evaluation of results by team members of similar skills and competence to those who produced the work. This process is educational, not judgmental or punitive. Peer review is a means for team members to hold each other accountable for the care and service they provide to patients.

Planning, organizing, directing, and controlling reflect a systematic, proactive approach to management. This approach is used widely in all types of organizations, including healthcare.

SAFETY ALERT Improving patient safety is an important function of the nurse manager. In doing so, the nurse manager must identify errors in patient care and help staff learn from those errors. When using errors as a teaching tool, it is essential that the manager do so without singling out the staff member or members who committed the error or attaching blame to those individuals.

Principles of Management

In addition to understanding managerial functions, nurse managers must have knowledge of the basic principles of management, including authority, accountability, and responsibility. As discussed in prior exemplars, *authority* is the right to direct other individuals and their activities. It is an integral component of managing. Authority is conveyed through leadership actions. It is largely determined by the situation and is always associated with responsibility and accountability. Managers must accept the authority granted to them.

Accountability is the ability and willingness to assume responsibility for one's actions and to accept the consequences of one's behavior. Accountability can be viewed as hierarchic, starting at the individual level, then the institutional or professional level, and finally the societal level. At the individual or patient level, accountability is reflected in the nurse's ethical integrity. At the institutional level, it is reflected in the statement of philosophy and objectives of the nursing department and in nursing audits. At the professional level, it is reflected in standards of practice developed by national or provincial nursing associations. At the societal level, it is reflected in legislated nurse practice acts.

Responsibility is an obligation to meet objectives and perform tasks. Managers are responsible for resources, employee performance, team building, and conflict resolution. They are also responsible for the way the team manages its time.

Managing Resources

One of managers' greatest responsibilities is their accountability for human, fiscal (financial), and material resources. Budgeting and determining variances between actual and budgeted expenses are crucial skills for managers. For more information about the allocation of resources, see the module on Healthcare Systems.

Enhancing Employee Performance

Managers help employees develop their skills by identifying appropriate learning opportunities, facilitating attendance

at professional workshops and conventions, and encouraging achievement of advanced education, such as higher degrees or certifications. The nurse manager who empowers other nurses by providing information, support, resources, and opportunities will have team members who are more committed to the institution, more effective in their roles, and more confident in their abilities. These nurses are also better able to meet their own goals and to help the institution achieve its goals.

Building and Managing Teams

The manager is responsible for building and managing the work team. A manager who is familiar with the group process will be able to lead the group in a manner that promotes its development into an effective work team.

The term *group process* is used to summarize how a group works together to complete tasks. One of the elements of the group process is ensuring that all team members understand the team's purpose and their own individual roles, as well as those of other team members. Another element is helping each team member feel that his or her contributions are recognized by the manager and other team members. Yet another way that nurse managers can promote more effective group processes is through recognition and appreciation of the differences among staff members, as described in the Focus on Diversity and Culture.

Good communication within the team is also important. Effective communication promotes good personal relationships among team members and fosters a common understanding of the team's purpose, barriers faced, and opportunities for improvement. A healthcare team often consists of nurses, physicians, therapists, and unlicensed personnel who have different training and backgrounds. These individuals do not share the same vocabularies or medical knowledge, which can hamper communication. On teams such as these, it is particularly important for the nurse manager to facilitate good communication.

Evaluating the group's work is another responsibility of the manager. Effectiveness, efficiency, and productivity are three frequently used outcome measures. In healthcare, **effectiveness** entails providing services based on scientific knowledge to all patients who could benefit and refraining from providing services to those not likely to benefit (i.e., avoiding overuse and underuse). **Efficiency** is avoiding waste, in particular waste of the equipment, supplies, ideas, and energy used to provide nursing services. Finally, **productivity** is a performance measure of both the effectiveness and efficiency of nursing care. Productivity is frequently measured by the amount of nursing resources used per patient or in terms of required versus actual hours of care provided.

Managing Conflict

Nurse managers are frequently in a position to manage conflict between individuals and among groups or teams. Conflicts may arise from differing values, philosophies, or personalities. In healthcare, conflict can also arise as a result of competition for resources.

A nurse can use any of the available methods for managing conflict, each of which has its advantages and disadvantages. (See the module on Collaboration.) New nurse managers

Focus on Diversity and Culture

Embracing Staff Diversity

Today's nursing workforce is increasingly diverse, not only in terms of culture and ethnicity, but also in terms of age, experience, education, gender, religion, and many other factors. Increased diversity is beneficial, because it means America's nurses are better equipped than ever before to address the needs of a rapidly changing population. However, if not properly addressed and embraced, diversity among staff members can also serve as a potential impediment to communication, teamwork, and effective group processes.

Nurse managers play a key role in harnessing the benefits of a diverse workforce. First and foremost, they are responsible for enforcing legal and organizational requirements that prohibit workplace discrimination and harassment, as well as for ensuring that members of their staff do not engage in other forms of prejudicial behavior toward patients or one another. Perhaps more importantly, nurse managers can and should promote the celebration of diversity among their employees. Strategies for recognizing staff diversity and promoting inclusiveness include (but are not limited to) the following:

- Offering foreign language training to staff members
- Conducting educational sessions about communication preferences and/or healthcare practices among different cultures

- Using inclusive, nonbiased terminology when interacting with patients and staff
- Allowing staff members to discuss how their personal beliefs affect their feelings about different cultures
- Inviting staff members from different ethnic and religious groups to discuss how they might address specific scenarios in light of their culture
- Recognizing holidays celebrated by staff members from different backgrounds
- Selecting staff mentors and other unit leaders who place high value on cultivating a culturally diverse staff
- Not forcing employees from diverse backgrounds to conform to the behavior of the prevailing culture
- Encouraging open, honest, and respectful communication among staff

Measures such as these promote an environment of learning, cooperation, and personal growth in which all employees feel valued. This, in turn, contributes to more effective patient care.

St. Louis, MO: Elsevier Mosby.

may require training to become proficient in the use of these methods.

Managing Time

The effective nurse manager uses time effectively and assists others to do the same. Many factors inhibit good use of time, such as personal task preferences, emergencies or crises, and

unrealistic demands from others. Strategies that the manager—and all nurses—can rely on in order to use time efficiently include setting goals and arranging priorities, with urgent tasks prioritized first; delegating tasks when possible; learning to ask for help when necessary; using regular schedules to avoid interruptions and limit time spent on activities; and striving to achieve balance (Froedge, 2013).

REVIEW Leadership and Management

RELATE Link the Concepts and Exemplars

Linking the exemplar of leadership and management with the concept of quality improvement:

1. What impacts might shared leadership and shared governance have on the quality improvement process?

Linking the exemplar of leadership and management with the concept of communication:

2. What is the nurse manager's role in improving communication at the time of patient hand-offs to promote patient safety?
3. Can an individual with poor communication skills act as a competent leader? Why or why not?

REFLECT Apply Your Knowledge

Taylor Bradakis graduated two years ago and worked in labor and delivery after graduation. He recently was transferred to the neonatal

ICU. Martha Rivaldo is a staff nurse on Taylor's new unit; she has been in the ICU for 13 years and has a reputation for being an exceptionally skilled and competent nurse. She also has a reputation for being critical and unkind to new nurses on the unit. Taylor has yet to have an unpleasant encounter with Martha, but he has overheard her complaining to her friends about younger staff members and about the way the unit is managed. Several nurses confide in Taylor that they have complained about Martha to the nurse manager, but the nurse manager never does anything about her behavior. Instead, the nurse manager simply says, "How do you suggest correcting this issue?"

1. Is Martha a leader? Explain your answer.
2. Why might the nurse manager ask for staff nurses' input when they report problems with Martha?
3. If you were the ICU nurse manager and you had received several complaints about Martha's behavior, how would you respond?
4. What is Taylor's best course of action when he overhears complaints from both Martha and the other nurses on the unit?

Nurses hold the public's trust. In Gallup's annual survey of professions released on December 6, 2015, 80% of Americans called nurses' honesty and ethical standards either high or very high (Gallup, 2015). Nurses have topped Gallup's honesty and ethics ranking survey every year but one since being added to the list in 1999 (the exception being 2001, when the list included firefighters), and nursing continues to be the most well respected of 11 professions (Riffkin, 2014). At a time when the field of healthcare is in turmoil, this is a remarkable accomplishment.

Nurses are visible and present across the continuum of healthcare services, advocating for and caring for patients through the many facets of health promotion, education, maintenance, and restoration. Nurses may be found in diverse healthcare settings, including acute hospital settings, clinics, public health departments, private practice, hospice centers, birthing centers, schools, pharmacies, and doctors' offices. Nursing care extends beyond the confines of institutions and facilities. It is given in parish ministries, on military bases and in mobile field hospitals, at children's camps, at community health fairs, at motor vehicle crashes by emergency flight nurses, at places of employment in corporate health clinics, and in patients' homes. Nurse educators and researchers practice in colleges and universities and in clinical settings, and there are school nurses in schools

and colleges. Nurses are accessible 24 hours a day in the acute setting and may also be available via telehealth lines. Given that they interact so often with the community in health and wellness, in sickness, at work, at school, or at recreation sites, is it any wonder that nurses have secured trust in the community?

The first step in fostering trust is to be present and engaged in a professional manner. How then does the nursing profession, with such a large and varied practice arena, define professional behaviors for nurses?

Components of Professionalism in Nursing

Upon receiving their licenses, members of the nursing profession commit to a fundamental social contract that sets rules to guide the professional conduct of licensed registered nurses (American Nurses Association [ANA], 2016). Nurses, however, do not become professionals just by receiving a license. According to Dinmohammadi, Peyrovi, and Mehrdad (2013), nurses learn the complexities of professionalism over the course of years of engagement with comprehensive educational programs, competent role models, and field experiences. As nurses pass through the stages of "learning, interaction, development, and adaptation," they gradually

TABLE 40–1 Characteristics Exhibited by Professional Nurses

Characteristic	Description
Professional Behaviors	Nurses convey professionalism by adhering to dress codes, maintaining calm demeanors, refraining from inappropriate electronic media use, and demonstrating a strong work ethic.
Teaching and Learning	Nurses attain an expert level of nursing practice by actively engaging with both on-the-job learning opportunities and formal education programs.
Competence	Nurses demonstrate competence through rigorous application of universally accepted standards of care and evidence-based practice.
Collaboration	By working respectfully and communicating fluently with other members of the healthcare team, nurses display professional collaboration skills.
Advocacy	Nurses are accountable for advocating for patient safety and needs at all times and in all settings. Nurses act to reduce risk and improve patient outcomes.
Caring Interventions	By exemplifying a positive attitude and demonstrating compassion and cultural awareness for patients' needs, nurses provide a crucial aspect of patient care.
Ethics	By adhering to accepted nursing standards and considering the ethical implications of their actions, nurses protect patients and the healthcare team and demonstrate integrity.

learn to respond to novel situations with independent and creative applications of their nursing training. A brief overview of the characteristics of professionalism in nursing is presented in **Table 40–1** >>.

As the nursing profession expands to include the dynamic roles of case managers, nurse educators, and clinical nurse specialists, it is essential for nurses to educate the public to keep the image of nursing professionalism current (Hoeve, Jansen, & Roodbol, 2014). As the public and the healthcare team arrive at a coherent understanding of nursing as a healthcare profession in its own right, nurses gain incentive to perform to the best of their professional ability.

Professional Behaviors

One key component of professionalism is the nurse’s commitment to behaving professionally by looking and acting like a professional, acting autonomously, and demonstrating a commitment to nursing. As a member of the profession of nursing, the individual nurse is always being observed and judged as a representative of that profession, even when off duty. How a nurse dresses, behaves, and communicates sets the stage for the development of trust or mistrust. Most healthcare employers provide employees with guidance and expectations for proper attire and conduct. Although most facilities have specific policies, those of one healthcare facility might not be relevant in another facility, and best practices are constantly being revised in light of new findings on patient safety, public perception, and shifting cultural attitudes. However, there are commonly accepted guidelines about dress, professional demeanor, and electronic media use (see **Table 40–2** >>>).

Appearance also affects how others within the medical community see the nurse (**Figure 40–1** >>). Appearance is a form of nonverbal communication that evokes a response from others. Imagine a nurse talking on a cell phone while approaching a physician or other healthcare provider to question the validity of an order. Will the colleague have enough confidence in the nurse to accept the expressed concern and change the decision regarding the patient’s plan of care?

Behavioral factors also play a large role in the nurse’s self-identification and public presentation as a professional. In

the past, nurses have been seen as accessories to doctors, but as nursing knowledge and practices have developed, nurses increasingly act autonomously in delivering care and prescribing nursing treatments (Hunt, 2015). As nursing continues to be increasingly recognized as an independent profession, patients and other members of the healthcare team alike will prize nurses’ commitment to their profession and autonomy in performing their work.

An essential quality in acting with professionalism is demonstrating a strong work ethic. Nurses who go above and beyond to provide exemplary care, resolve conflicts, and collaborate respectfully with patients and the healthcare team will inevitably be seen as professionals.

Teaching and Learning

For generations, the on-the-job work of becoming a nurse has been considered a process of socialization. The old model of socialization carries with it a long history of

Figure 40–1 >> A professional appearance supports the nurse’s credibility.

TABLE 40–2 Common Guidelines for Professional Attire, Demeanor, and Electronic Media Use

Guidelines	Rationale
Professional Dress	
No excessive jewelry, long fingernails or artificial nails, or chewing gum	Avoidance of items that may harbor pathogens and threaten patient safety
Hair secured away from contact with the individual receiving care	Prevents contamination of sterile fields and spread of bacteria
Personal cleanliness, avoiding strong odors and perfumes	Prevents patient discomfort and annoyance Instills patient confidence and trust Shows respect for needs of allergic or nauseated patients
Clean uniform or clothing	Promotes good sanitation Builds patient trust
No visible body modifications or unusual ear piercings	Prevents patient discomfort
No tattoos visible on parts of the body not covered by scrubs	Shows respect for patients who find tattoos offensive
Professional Demeanor	
Avoid loud talking	Respect patients' need for rest
Maintain a positive attitude and instill hope	Encourages and shows respect for patients and families
Maintain a clean, uncluttered workstation	Shows respect for peers
Avoid taking personal calls at work	Keeps focus on patient care
Do not discuss personal problems with patients	Maintains professional boundaries
Never breach patient confidentiality	Avoids violation of HIPAA
Avoid gossiping with and bullying coworkers	Maintains and promotes civility and patient safety
Do not complain to patients or family members	Maintains professional boundaries
Do not use illegal substances	Shows respect for self and patient safety
Electronic Media Use	
Do not use personal cell phones to document patients	Prevents the sharing of photos, videos, and sound recordings that may violate HIPAA
Do not share patient information over social media	Avoids the violation of HIPAA Ensures that patient information cannot be shared or retrieved from servers later, even after the nurse removes the offending content from social media

subservient, dependent female roles, the acceptance of dominant behaviors for males, and a hierarchical structure in healthcare organizations. As an alternative to the socialization model of becoming a nurse, Benner et al. (2010) have formulated the concept of **formation**, a process that facilitates the transformation of an individual from a layperson to a professional nurse. Formation is an evolutionary process that requires the acquisition of lifelong learning, experience, technical expertise, and interdependent professional collaboration. The resulting integration of the nurse's thoughts, feelings, behavior, education, experience, and ethical behavior contributes to the formation of a professional nurse through the progressive stages of novice, advanced beginner, competent, proficient, and finally expert. Transformation can occur only with personal commitment to self, individuals, the community, organizations, society, and the profession. More information on the formation model can be found in the module on Accountability.

Continuously gaining knowledge is central to providing high-quality care and maintaining patient safety. Nursing students are required to learn the information the entry-level practicing nurse needs, but learning does not stop at graduation. Once licensed, nurses are expected to maintain and update their knowledge base throughout their career by

engaging in continuing education programs and maintaining their licensure. Healthcare is changing constantly as new drugs enter the market, new treatments and technology are introduced, and ongoing research confirms or calls into question the effectiveness of past information. If nurses do not participate in continuing education, their knowledge base quickly becomes obsolete, and their practice may even endanger patients. Each state's board of nursing outlines requirements for nurses to participate in classes designed to help maintain and improve their knowledge (ANA, 2010). Many nurses also choose to pursue advanced degrees in nursing and other healthcare fields. See the module on Teaching and Learning for more information on the nurse as a student.

Accountability

A key component in nursing professionalism is accountability to expected standards of care. Organizations such as The Joint Commission, the ANA, and the National League for Nursing (NLN) define standards of care against which nurses' performance is measured (Davis, 2014). A nurse's competence, or ability to perform the job correctly, is the practical measure of accountability. The expectation of competence begins when the student enrolls in a nursing

program and continues throughout nursing practice, whether the nurse is caring for patients, managing a department, or acting in an advanced practice role. The nurse must learn how to operate new equipment before it is put into general use; maintain an evidence-based practice that is current on the latest findings; and seek help from peers, mentors, and instructors to learn new skills and techniques. Each nurse is responsible for pinpointing his or her own areas of strength and weakness. Once an area of incompetence has been identified, the nurse should seek opportunities to gain competence in that area. This self-examination is a necessary ingredient in the formation of a truly professional nurse.

Nursing is defined as a profession in part because nurses are guided and assisted by professional organizations. In addition to the state boards of nursing and the National Council of State Boards of Nursing (NCSBN), which license nurses and define the standards of safe conduct, nurses can join a large number of professional organizations that promote information sharing, community building, and problem solving within the nursing profession. Nurses can join these organizations as a way of continuing their education and keeping up-to-date on the most recent developments in nursing practice. The module on Health Policy fully describes the professional organizations that govern and differentiate the profession of nursing.

Collaboration

How to work as a member of the team is discussed in detail in the module on Collaboration. Skill in working as a team member contributes to others' opinions of the nurse as a professional and improves the quality of care delivered to the patient.

Clinical Example A

Caroline Nava is a 28-year-old nursing student who is enrolled in her final clinical rotation and due to graduate in 2 months. She is working on a surgical unit managing care for five individuals. After completing her charting, she leaves the nursing unit 2 hours late. She returns home, exhausted from a particularly busy clinical day. Just as she sits down to enjoy some relaxation time, she remembers that she failed to obtain information from the chart of a new postoperative patient. Earlier today, her instructor asked Caroline to report back to her about this individual's laboratory results by the end of the day. The patient returned to the unit late from postanesthesia care, as Caroline was about to leave.

Caroline begins to panic and is uncertain what to do. Suddenly, she remembers that her friend Joan McIntyre, another student, is in clinical on the same unit until late that evening. Caroline calls Joan and asks her for a favor. She explains to Joan that she is in a bind and has to call her nursing instructor with the information as soon as possible. Caroline asks Joan to take a picture with her cell phone of the laboratory results in the patient's chart and send her the picture. Joan is glad to be able to help her friend and successfully sends the information to Caroline. Caroline is able to contact her instructor with the necessary information about her patient.

Critical Thinking Questions

1. Do you think Caroline handled the situation ethically? Support your answer.
2. If you were Joan, what would you have done in this situation?

Advocacy

Advocacy, the practice of expressing and defending patients' needs, is an essential component of professional nursing practice. The ANA Code of Ethics for Nurses emphasizes patient advocacy as a key concern (see the module on Ethics for more information). A nurse may be a patient advocate by conveying a patient's wishes to members of the health-care team, by communicating with the patient's family, or simply by encouraging the patient to express his or her wishes. Patient advocacy is essential for patients in vulnerable populations, such as patients with disabilities or mental health diagnoses. Promotion of an organizational culture that is conducive to patient advocacy is of central importance to the development of a professionalism rooted in advocacy (Choi, 2015). See the module on Advocacy for more information.

Caring Interventions

The caring interventions of attitude and compassion are key to nursing professionalism. *Attitude* is a mental state involving values, beliefs, feelings, and mood. Each individual's attitude affects the individual and all others who are nearby. Professional behavior for the nurse includes maintaining a positive attitude while working with patients, their family members, and other healthcare professionals. A nurse with a positive attitude refrains from complaining and expresses an optimistic outlook. The Via Christi Health System survey revealed that nurses themselves view a positive attitude as an essential component of professionalism (Via Christi Regional Medical Center, 2003). Attitude is discussed in more detail in the exemplar on Work Ethic in this module.

Compassion is an awareness of and concern about other individuals' suffering. Nurses demonstrate compassion when they recognize a patient's need and respond appropriately to meet that need. In showing compassion, the nurse treats the patient as a unique and special individual and not as a number or a diagnosis. The nurse further demonstrates compassion by advocating in the community and communicating with politicians to develop laws that protect and promote the health of individuals and families. See the module on Caring Interventions for more information on compassion and attitude.

Ethics

As professionals, nurses adhere to the ANA Code of Ethics for Nurses, as well as evaluate the potential for any ethical conflicts between one's own ethical code and one's work as a nurse. Nurses who successfully engage in consistently ethical behavior demonstrate **integrity**, or adherence to a strict moral or ethical code. For nurses, integrity involves consistent behaviors based on the internalization of the values, ethics, and best practices of the profession of nursing. Nurses demonstrate integrity by accepting feedback (positive or negative) as a tool for improving their delivery of patient care, by maintaining accountability for their actions and freely admitting when they make mistakes, and by following their state's nurse practice act and never working outside their scope of practice.

Concepts Related to Professionalism

Professionalism is a central component of all effective nursing actions. Being professionally engaged enables nurses to make accurate assessments, perform caring interventions, collaborate, make clinical decisions expediently, and teach with compassion and care. How the concepts of accountability, collaboration, advocacy, and ethics relate to professionalism are outlined elsewhere in this module. Communication and application of culturally respectful, caring interventions through the nursing process are key elements valued by nursing students and nurses, especially in contrast to other members of the healthcare team (Delunas & Rouse, 2014). The profession of nursing is based in teamwork and respectful communication with patients as well as colleagues, and nurses must be fluent communicators to attain expert status.

Nurses' success within the discipline is predicated on a careful adherence to codes of ethics in all healthcare settings for all patients. According to Kangasniemi et al. (2013), the role of professional nurses is to incorporate ethical values of patient safety into decision making for nurses at every level of a healthcare organization or system, so that nurses in all roles consider ethical values when administering care.

Professional nurses are above all accountable to deliver the highest standard of care, which include as a crucial component caring interventions. Horsburgh and Ross (2013) found that nursing programs should prepare students for the necessity of delivering safe, culturally competent, and compassionate care despite busy schedules, an intervention that can be aided in practice by nurses' membership in nursing organizations and ongoing education programs. Some, but not all, of the concepts integral to Professionalism are outlined in the Concepts Related to Professionalism feature. The concepts are in alphabetical order.

Concepts Related to Professionalism

CONCEPT	RELATIONSHIP TO PROFESSIONALISM	NURSING IMPLICATIONS
Caring Interventions	Professional behaviors help nurses provide caring interventions to patients and themselves.	<ul style="list-style-type: none"> ■ Practicing theories of caring contributes to comprehensive patient care. ■ Emphasizing caring facilitates patients' empowerment. ■ Engaging in self-care contributes to holistic personal and professional wellness.
Clinical Decision Making	Nurses who engage in professional behaviors are better able to provide high-quality, evidence-based nursing care at all stages of the nursing process.	<ul style="list-style-type: none"> ■ Use careful reasoning during assessment to ensure accurate and timely assessment while providing maximum comfort to the patient. ■ Use clinical decision making to determine priorities for care to ensure the best outcomes for the patient. ■ Use clinical decision making to determine the timing and order of interventions to promote patient trust and comfort.
Communication	Professional behaviors promote reliability and accountability for information and the methods by which it is conveyed.	<ul style="list-style-type: none"> ■ Establish trust and rapport with patients and team members. ■ Ensure accurate and complete documentation and reporting, decreasing risks to patient safety.
Culture and Diversity	Professional standards of nursing require the nurse to work toward cultural competency and refrain from imposing the nurse's own values on the patient.	<ul style="list-style-type: none"> ■ Assess patient and family cultural needs and practices. ■ Ensure that care provided incorporates patient and family cultural needs and practices whenever doing so will not cause injury to the patient. ■ Support the patient and family in maintaining cultural practices and rituals in outpatient, inpatient, and home care settings.
Healthcare Systems		<ul style="list-style-type: none"> ■ By participating in primary prevention using evidence-based standards and professional guidelines, the nurse can help promote the health of the individual and the larger community. ■ By assessing the patient's insurance status and ability to access healthcare, the nurse can assist the patient in finding affordable and practical ways to meet healthcare needs.
Safety	Professional behaviors ensure that nurses follow safety guidelines and the principles of evidence-based practice.	<ul style="list-style-type: none"> ■ Maintaining current knowledge of evidence-based practice facilitates patient safety. ■ Administering interventions according to knowledge of best practices across the lifespan promotes optimal health outcomes. ■ Maintaining a sense of one's own physical limits and boundaries promotes nurse and healthcare team safety.

Unprofessional Behaviors

Unprofessional behaviors undermine an individual nurse's credibility and negatively affect group morale, and they may affect patient outcomes.

Types of Unprofessional Behaviors

Unprofessional behaviors come in many forms, but they all make members of the healthcare team and patients feel uncomfortable, hurt, intimidated, threatened, or targeted in ways that interfere with the provision of high-quality patient care (Stringfellow, 2016). Some examples of unprofessional behaviors include the following:

- Belittling someone's opinion or using patronizing language
- Delivering negative or disparaging nonverbal messages
- Engaging in constant criticism, scapegoating, and fault-finding
- Engaging in elitism about experience, education, or practice area
- Undermining someone's activities or causing unnecessary disruptions
- Having emotional outbursts
- Being reluctant to answer questions
- Pitting staff members against one another and propagating rumors

Unprofessional behaviors such as breach of confidentiality, as defined by state nurse practice acts, are discussed in the module on Legal Issues. Other unprofessional behaviors, such as substance abuse and discrimination, are discussed in other modules. Unprofessional behaviors such as excessive absenteeism and tardiness are discussed in the exemplar on Work Ethic in this module.

It is important to recognize that the work environment sometimes carries over to social events, such as unit parties, company picnics, and informal gatherings. The rules of professionalism and the pitfalls of unprofessional behavior extend to these types of situations as well.

Abuses of Power

Any discussion of unprofessional behavior must include a discussion about abuses of power. An **abuse of power** is any attempt to use one's position or authority to shame, control, demean, humiliate, or denigrate another individual in order to gain emotional, psychologic, or physical advantage over that individual. In any professional environment, including the nursing profession, abuses of power such as sexual harassment, improper use of authority, bullying, and intimidation must be addressed immediately and appropriately.

SAFETY ALERT Acting with professionalism is not merely a matter of ensuring group cohesion and mutual respect. Behaving professionally is essential to healthcare workers' ability to ensure patient safety. According to the Agency for Healthcare Research and Quality (2014), 77% of healthcare staff report witnessing physicians engaging in disruptive behavior, and 65% report nurses engaging in these communication patterns. Most healthcare staff also believe that disruptive actions increase the potential for medical error and preventable deaths. Disruptive behaviors have been tied to nurses' workplace

dissatisfaction in addition to sentinel events in the operating room. There is no standard healthcare definition of disruptive behavior, but it is commonly defined as any behavior that shows disrespect for others or impedes the delivery of patient care.

Bullying

Evidence of bullying, lateral violence (violence directed toward peers), and incivility in the healthcare environment has been well documented in nursing research for over three decades. These behaviors are commonplace because of widespread tolerance within the healthcare arena. Furthermore, the long history of a hierarchical or tiered power structure perpetuates the dominance and empowerment of unprofessional individuals. The Joint Commission has identified "behaviors that undermine a culture of safety" in healthcare (such as bullying and incivility) as being among the leading causes of sentinel events (Wyatt, 2013). The Joint Commission calls for zero tolerance of intimidation and bullying in the workplace and recommends that healthcare facilities implement policies to stop such bullying. See the Evidence-Based Practice feature for more information.

Sexual Harassment

According to the Equal Employment Opportunity Commission (EEOC), the definition of sexual harassment is "unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature" (Code of Federal Regulations, 2009). Because sexual harassment violates the harassed person's rights, it is a form of discrimination. The law against sexual discrimination in 1987 was held to apply to all federally funded educational and employment institutions. According to the 2009 Code of Federal Regulations, sexual harassment occurs in any of the following circumstances (Code of Federal Regulations, 2009):

- An individual's employment is conditional on compliance with sexual requests or tolerance of sexual behavior, regardless of whether that condition is explicitly stated or simply implied.
- Employment decisions that affect the individual, such as promotion, are based on whether that individual consents to a sexual request or tolerates sexual behavior. (Whether the individual consents to or rejects the sexual request or behavior is irrelevant; it is sexual harassment in either event.)
- Sexual conduct interferes with an individual's performance on the job or creates an "intimidating, hostile, or offensive working environment."

The victim or violator may be either male or female in any of these cases, and it is not necessary for the victim and violator to be of the opposite sex.

To handle any sexual harassment they may encounter in the workplace, nurses must develop their assertiveness skills to be able to say no when necessary. They must also familiarize themselves with the sexual harassment policy and procedures at the institution that employs them. They must know the procedure for reporting sexual harassment (including to whom they should report incidents), the investigative process, and how their confidentiality will be protected and to what extent.

When providing patient care, nurses must use caution to avoid having patients misinterpret nursing behaviors as

Evidence-Based Practice

Bullying and Disruptive Behavior in the Workplace

Problem

Bullying and disruptive behaviors in the healthcare environment are top causes of sentinel events, and recent evidence links behaviors that undermine a culture of safety directly to medical errors (Wyatt, 2013).

Evidence

Over the past several decades, the phenomenon of disruptive behavior in the healthcare environment has been referred to as *lateral violence*, *incivility*, and a variety of other names. The existence of disruptive behavior is well documented in nursing research. Walrafen, Brewer, and Mulvenon (2012) describe disruptive behaviors as overly aggressive behaviors such as yelling, verbally dismissive and demeaning remarks, and the use of denigrating terms. Covert and overt actions are defined as verbal outbursts and physical threats as well as passive reluctance or refusal to answer questions, failure to return phone calls or pages, use of condescending language or voice intonation, and impatience with questions. A quantitative review of the literature on nursing violence that analyzed data from 136 articles gathered from 160 samples of 151,347 nurses revealed an exposure rate of 66.9% for nonphysical violence (Spector, Zhou, & Che, 2014). Even gossip, which might seem benign on the surface, is a frequent form of bullying in the workplace. Students and novice nurses are particularly vulnerable

to bullying because of their lack of experience and power. In a study of 147 novice nurses, Berry et al. (2012) found that 72.6% of respondents reported a bullying event in the previous month. Workplace productivity was negatively affected by bullying, which reduced the novice nurses' ability to handle the cognitive demands of their workload.

Implications

The Institute of Medicine (2010) has challenged nurses to lead the way to changing and improving quality, efficiency, and safety in the healthcare environment. Nurses must possess and use good communication and conflict resolution skills to address bullying in the workplace and transform the healthcare environment in which they practice. The continued training of point-of-care nurses in assertiveness and leadership skill is necessary to effect a change.

Critical Thinking Application

Bullying is a threat to patient safety and the emotional well-being of nurses. What measures might a student or novice nurse use to address bullying by more experienced nurses in the healthcare setting? Describe a situation in which you may have observed or experienced incivility. Write down practical comments you would feel comfortable making to address the behavior in real time.

sexual harassment. For example, in lifting a patient's breast to bathe the chest or to place leads when performing an electrocardiogram, it is best to use the back of the hand rather than the palm of the hand. It is also important to explain the procedure and seek the patient's permission. In this way, the nurse can reduce the possibility that the action will be misinterpreted as sexual harassment and can avoid responses by the patient that might tend toward sexual harassment of the nurse.

Improper Use of Authority

Improper use of authority is widespread and has no place in the practice of nursing. Some nurses who, through use of their professional skills, have acquired administrative titles remove "Registered Nurse" from their title or name badge, perhaps to disassociate themselves from nursing's professional code of ethics. Once separated from the codes of ethical behaviors expected of nurses, bullies in administrative positions adopt a corporate rather than a professional demeanor and attitude. Such administrators serve their careers and no longer the priorities of patient-centered care. They can be identified by their attitude of arrogance, control, and acceptance of the hierarchical power structure that oppresses and is condescending to the voice of nursing at the point of care.

A nursing manager may use intimidation to show favoritism and to foster subordinate compliance, bias, and group pressure to exclude employees toward whom the manager has a less favorable attitude or who challenge the manager. Nurses in authority who emphasize principles over personality and who focus on patient safety can extinguish these negative behaviors and encourage nurses at the point of care. Nurses can facilitate effective leadership

by becoming active in nursing leadership organizations such as the American Organization of Nurse Executives (AONE) and the ANA Leadership Institute following licensure and by lifelong learning within the discipline to promote professionalism and support the larger nursing community. Transformational leadership, which is discussed in the exemplar on Management and Leadership Principles in the module on Managing Care, is recommended as the leadership style for facilitating progress and innovation in nursing.

Clinical Example B

Mary Reynolds, who is a nurse of the baby-boomer generation, disagrees with Ashley Maloney, a new graduate, about how Ms. Maloney handled a situation with a patient's family. You overhear Ms. Reynolds telling a friend of hers that she hopes that Ms. Maloney never takes care of her or her family. Later, while you are on break, Ms. Reynolds repeats to you her story about Ms. Maloney. She informs you that Ms. Maloney "ignored the family" sitting at the bedside and that the family complained to Ms. Reynolds. She apologized for Ms. Maloney and told the family, "She is a problem. Thanks for telling me. I will take care of it for you." The family rewards Ms. Reynolds by writing a supportive note to the nurse manager about her and also detailing their perception of how Ms. Maloney dealt with their family.

Critical Thinking Questions

1. Using your knowledge of formation of professional behavior and bullying, how might you respond to Ms. Reynolds?
2. Using what you have learned about communication, frame a respectful confrontation of Ms. Reynolds.
3. If you were the nurse manager, how would you handle this situation while applying a provision of the ANA Code of Ethics?

Intimidation

Intimidation is bullying, threatening, or forcing someone who is physically or emotionally weaker to do something (or refrain from doing something) in order to avoid retribution. It is never appropriate for a nurse to threaten someone, whether a coworker, a patient, a patient's family member, or anyone else. Intimidation can be subtle, such as standing close to another individual with a hostile look on one's face,

or it can be overt, such as telling someone to do something or that person will be "sorry." Even nurses with the best of intentions may not realize that they are using intimidation when they say things like "If you don't take your medicine [or go to physical therapy, or follow the treatment plan], you're only going to get worse." Even though what the nurse says may be true, this approach is intimidating and lacks professionalism.

REVIEW The Concept of Professionalism

RELATE Link the Concepts

Linking the concept of professionalism with the concept of addiction:

1. What impact does a nurse's use of addictive substances (legal or illegal) have on the practice of nursing?
2. What is your professional responsibility when a nurse on your unit appears to be under the influence of a substance?

Linking the concept of professionalism with the concept of clinical decision making:

3. How do professional behaviors result from effective clinical decision making? How do competent clinical decisions stem from professional behaviors?
4. What conclusions would you draw, or have you drawn, about a nurse's ability to make clinical decisions on the basis of the nurse's professional or nonprofessional behaviors?

REFLECT Apply Your Knowledge

Cheryl Goodwin is a nurse executive who is widely respected for her rapport with nurse educators. She is the dean of a nursing college and is a doctoral-prepared nurse who maintains a small private practice. She is active in state organizations and willing to help both faculty and students. A hospital administrator calls Ms. Goodwin in for a private meeting. In the course of the meeting, Ms. Goodwin is told that a faculty member in the nursing college has committed an act of abuse and neglect toward a patient in the hospital. The Chief Nurse Executive (CNE) of the hospital, who is also at the meeting, informs Ms. Goodwin that the faculty member is no longer permitted to practice at that hospital.

Upon questioning the faculty member involved, Ms. Goodwin discovers that the individual did in fact commit the offenses willfully, as reported by the CNE. Ms. Goodwin informs this faculty member that his actions created dire consequences for the patient involved and that his position at the college is terminated. He had been on probation for bullying and maltreatment of students before this incident.

The college administration permits the nursing faculty member to resign his position. He then begins a campaign to attack Ms. Goodwin, accusing her of making a number of false accusations. Friends rally around the dismissed employee, who has taught at the college for a number of years. He has been known for covering for and doing favors for other faculty members for extra cash, such as picking up an extra clinical day, and for granting favors to the faculty members who reported to him. As a senior faculty member, he also coordinated clinical rotations and scheduling.

Ms. Goodwin is not at liberty to discuss the incident that led to this faculty member's resignation. The other faculty members at the college are not aware of the consequences suffered by the hospital patient and family. The hospital has requested that the situation remain confidential, as the family has not been notified of the abuse. Faculty members who have known Ms. Goodwin for many years begin questioning her motives and labeling her as "sick." They talk behind her back and do not invite her to nursing functions that she has always attended. They bully any faculty member who associates with her. Ms. Goodwin acquires another position and leaves a position that she loved.

1. How would you describe the behaviors and actions of the faculty members in the scenario?
2. What recourse does Ms. Goodwin have?
3. Why do you suppose the faculty members who had a prior satisfactory relationship with Ms. Goodwin did not support her? Do you believe they did the right thing? How and why might they have handled the situation differently?

Exemplar 40.A Commitment to Profession

Exemplar Learning Outcomes

40.A Analyze commitment to profession as it relates to professionalism.

- Describe factors associated with professional commitment.
- Describe types of commitment.
- Outline the stages of the commitment process.
- Discuss ways to manage stress associated with commitment to a profession.

Exemplar Key Terms

Affective commitment, 2653
Burnout, 2654
Commitment, 2653
Continuance commitment, 2654
Normative commitment, 2654
Organizational commitment, 2653

Overview

Many experienced nurses view nursing as a vocation or calling. It is not a job or what they *do*; it is a part of who they *are*. They have made a commitment to their profession, incorporating the ethics and expectations of nursing into every aspect of their lives, whether at home, work, or play. This commitment is in essence a duty to the individual who is at the center of nursing care. Over time, some nurses may confuse professional commitment with organizational or corporate commitment.

Merriam-Webster's Online Dictionary (n.d.) defines **commitment** as “the state or an instance of being obligated or emotionally impelled.” To understand the term *commitment* as it is applied to the profession of nursing, one must first look at the concept of organizational commitment. The most widely accepted definition of **organizational commitment** is that it is the relative strength of an individual's relationship to and sense of belonging to an organization. Although organizational commitment and professional commitment may intersect, it is important for nurses to distinguish between the two. Experienced nurses can cite many instances in which nursing ethics and corporate goals collide. The business of healthcare and the provision of care to the patient are not always the same issue. The nursing profession holds the trust of the community and individuals in our society. With this trust comes the moral responsibility of nurses to address the needs of patients and to advocate for safe care within the business of healthcare.

The IOM (2010) calls for nurses to step up and lead the transformation of healthcare and to protect a caring model within the business model of healthcare. It is essential for the safety and well-being of all individuals in our society that nurses be actively involved in health policy and the financial decisions that affect the delivery of care. The nurse's commitment must be synonymous with professional commitment, even when it may be at odds with organizational commitment.

Factors of Professional Commitment

Factors associated with professional commitment include the following:

1. A strong belief in and acceptance of the profession's code, role, goals, values, and morals.
2. A willingness to exert considerable personal effort on behalf of the profession.
3. A strong desire to maintain membership in the profession.
4. A pattern of behaviors congruent with the nurses' professional code of ethics.

As was discussed earlier, nursing education concerns not only teaching students how to think like nurses and perform nursing tasks but also is charged with the acculturation and formation of professional behaviors in students and novice nurses. This process begins when the student enters the first nursing class. Many of the policies and rules associated with a nursing program are intended to prepare the student for entry into the profession of nursing. The student who violates or ignores school policy is in danger of becoming the nurse who ignores practice and agency policy. For example, tardiness in coming to clinicals may result in significant consequences for the offender. Time and attendance are critical

in nursing, as patients depend on the nurse for their safety. Especially during a nursing shortage, the nurse who is chronically late for work or excessively absent is subject to disciplinary action that could include suspension and termination. With frequent staff shortages, it is even more important for managers to be able to rely on staff members to be on the job when scheduled. Chronic lateness and frequent absenteeism place a greater burden on colleagues, compromise patient care, and lead to conflict among staff.

The values and goals of professional nursing are clearly delineated by standards of nursing practice, codes of ethics, nurse practice acts, national patient safety goals, accrediting agencies, and many other such resources. Entering the nursing profession is not just taking a job. It is assuming the obligation to protect, advance, and promote the health of self, individuals, and groups in the community, and it involves many role expectations not inherent in occupations that are just jobs.

Most students can easily identify with the willingness to exert considerable effort on behalf of the profession. Nursing programs have high standards of admission, and many programs receive far more applications than they have openings available. In times of economic recession, this imbalance is even more evident as displaced workers seek job security in the healthcare professions that have staff shortages. Nursing education is a rigorous program of study requiring considerable time and effort to prepare for entry into a demanding yet rewarding profession. The applicants who are accepted into nursing programs tend to be those who have demonstrated the ability to expend such time and effort to achieve their goals.

Students also can identify with the strong desire to maintain membership in the profession. Most students have already made sacrifices while taking related general education and science courses in preparation for the nursing major. The sacrifices required during nursing courses are even greater, as the number of hours required per credit earned increases when hours spent in lab and clinical are added. Most students who are accepted into a nursing program have a strong desire to complete the program, especially as their time in the program increases.

After graduation, the commitment to maintain membership in the nursing profession is demonstrated by membership in professional organizations and on various committees and by contributing to community organizations seeking input on laws related to healthcare and health promotion. Nurses must always maintain current knowledge related to changes in healthcare and the profession of nursing to keep their nursing practice up to date and therefore keep their patients safe.

Commitment to the profession of nursing is an obligation to behave in accordance with accepted codes of nursing professional practice. Many facilities that employ nurses require drug screenings and criminal background checks to assist them in the selection of individuals with high moral standards and to protect the populations that they serve.

Types of Commitment

Three types of commitment describe the psychologic link between an individual and the decision to continue in a profession: affective, normative, and continuance. **Affective commitment** is an attachment to a profession and includes

Source: Charlotte Observer/Tribune News Service/Getty Images.

Figure 40-2 » Affective commitment leads nurses and other healthcare professionals to volunteer their services to help in disasters, such as the January 2010 earthquake in Haiti. Here, Tiffany Young, a pediatric nurse from North Carolina (center), holds a child with cholera who is receiving treatment.

identification with and involvement in the profession. Affective commitment develops when involvement in a profession produces a satisfying experience. The student or nurse who has a strong desire to continue in the profession, who is involved in keeping up with current information, and who becomes involved with profession-specific organizations and service activities demonstrates affective commitment (**Figure 40-2** »). This individual is in school or working as a nurse because of a desire to be a nurse.

Normative commitment is a feeling of obligation to continue in the profession. Normative commitment develops as a result of having received benefits or having had positive experiences through engagement in the profession. The nurse who enters the field or remains in it because personal or family experiences with illness have created a desire to work in the healthcare field exemplifies normative commitment.

Continuance commitment, or the awareness of costs associated with leaving the profession, develops when negative consequences of leaving, such as loss of income, are seen as reasons to remain. Individuals who experience this type of commitment do not manifest the same ties to the profession as do those who are motivated by affective or normative commitment. In general, such individuals are not inclined to promote their profession. These students and nurses are in the field for the money and job security.

Stages of Commitment Development

The commitment to a profession develops in stages. The first stage is the *exploratory stage*, in which individuals explore the positive aspects of the profession. An example of this stage is the excitement of nursing students during the first weeks of their program as they model their new uniforms and ransack their lab kits. Commitment that begins as exploration leads to a positive orientation toward the profession.

The second stage is the *testing stage*, during which individuals discover negative elements of the profession. In this stage, individuals start to assess their willingness and ability

to deal with those negative elements. Some nursing students never get beyond this stage and drop out of school or change majors, deciding that the sacrifices are not worth the effort or that they are not suited to the nursing profession.

The third stage is the *passionate stage* of commitment, which begins as the individual synthesizes the positive and negative elements from the first two stages. Students in this stage not only are willing to commit to the profession but also are willing to contribute to its well-being. These students are the ones who become involved in student nursing associations, serve as class officers, or volunteer for activities not associated with a grade.

The fourth stage is the *quiet-and-bored stage* of commitment, in which students settle into the humdrum routines of the nursing program. This stage often occurs during the middle or late middle of the nursing program, as students begin to become more comfortable in their role and feel less anxiety about their performance.

The *integrated stage* is the final stage of commitment. Individuals who reach this stage have integrated both positive and negative elements of the profession into a more flexible, complex, and enduring form of commitment. They act out their commitment as a matter of habit. These students are in the final stages of their nursing program and are beginning to see themselves as nurses, eager to take the NCLEX-RN® and begin employment. As new graduates, they will once again proceed through the stages of commitment while transitioning from being nursing students to being registered nurses.

Managing Stress

Part of a commitment to any profession is learning how to manage the stress associated with that profession. Although most nurses find healthy ways to cope with the physical and emotional demands of the profession, these demands do create stress that can be difficult to manage. Nurses in some situations are overcome and develop **burnout**, which is similar to the exhaustion stage of the general adaptation syndrome (see the module on Stress and Coping) and should be understood as a complex syndrome of behaviors. In extreme cases, burnout may cause affected nurses to abandon the nursing profession altogether. The signs that a nurse has succumbed to burnout include feelings of helplessness and hopelessness, a negative attitude and self-concept, and physical and emotional exhaustion.

The use of healthy stress management techniques can help nurses prevent burnout. The first step is to recognize their stress and how they respond to stress. Some common responses to stress are angry outbursts, fatigue, feelings of being overwhelmed, physical illness, and increases in coffee drinking, smoking, or the use of alcohol or other mood-enhancing substances. After the nurses learn to recognize their stress and how they personally react to it, they must identify the trigger situations that tend to provoke the most pronounced stress reactions in them. Going through this recognition process will help nurses choose the stress reduction techniques that are best for them, which include the following:

- To reduce tension, engage in quiet activities that are personally meaningful (such as reading, listening to music, soaking in a tub, or meditating) as a daily relaxation program.
- To direct energy outward, establish and follow a regular exercise program.

- To overcome a feeling of powerlessness in relationships with others, learn techniques to increase assertiveness and develop the ability to say no.
- Turn errors and failures into constructive learning experiences by learning to accept such missteps as a part of life. By recognizing that most people do the best they can but do not always succeed, nurses learn to open up about their feelings with colleagues, ask for help, and reciprocate by supporting colleagues in their times of need.
- By recognizing that no situation is perfect and that certain limitations always exist, nurses learn to accept what cannot be changed; acceptance can decrease negative responses to stress.
- To improve organizational policies and procedures that may generate stress, nurses may get involved in efforts toward constructive change.

- To constructively handle the feelings and anxieties of working in a high-stress setting, nurses may develop collegial support groups.
- To address workplace issues, nurses may participate in professional organizations.
- To help clarify their problems and reactions to those problems, nurses may seek counseling.

Few professions are as demanding as nursing, which imposes unusual work schedule requirements, heavy demands on time and energy, and great responsibility. The work that nurses do often involves life and death, and nurses must face that possibility every day. Although the work of nursing can be highly satisfying and meaningful for many nurses as they help patients survive trauma and cope with problems to improve their lives, sustained professional commitment is necessary to avoid potential burnout.

REVIEW Commitment to Profession

RELATE Link the Concepts and Exemplars

Linking the exemplar of commitment to profession with the concept of development:

1. How might nurses in different life stages commit themselves to the profession of nursing in different ways?
2. Describe the impact of the nurse's moral development, according to Kohlberg's theory, on commitment to the profession of nursing.

Linking the exemplar of commitment to profession with the concept of collaboration:

3. How is nurses' commitment to profession demonstrated by their ability and willingness to collaborate with others?
4. A nurse working on a medical unit is approached by a newly graduated licensed practical nurse who asks for help in improving her skill in initiating an IV catheter. How would nurses with different levels of commitment to the profession respond to this request?

REFLECT Apply Your Knowledge

Andrea Kamara is a nurse working on a very busy and often understaffed oncology unit. Two patients have died within the past week. They were both well known to the staff because each had been admitted several times with complications of their disease and treatment. The staff members who were working all cried, first for one patient and then, a few days later, for the other. Today, one of Ms. Kamara's assigned patients required cardiopulmonary resuscitation and was sent to the ICU, another developed septicemia and required many diagnostic tests and procedures, and a third was given bad news about her prognosis and was tearful and frightened. At the end of the day, Ms. Kamara felt that she had not done her best job because she was so busy. She wished she could have spent more time with each of her assigned patients, caring more for their emotional needs.

1. How will Ms. Kamara's commitment to the profession of nursing affect how she responds to her feelings of inadequacy and grief?
2. If Ms. Kamara is fully committed to nursing, how will she resolve her feelings about the quality of the care she delivers?
3. If Ms. Kamara has a continuance commitment to nursing, how will she respond to the shift she just worked and her feelings?

 Work ethic, 2656

Overview

A majority of employers identify a “strong work ethic” as the most important characteristic of a good employee. A belief in the importance and moral worth of work constitutes a **work ethic**. Because they place a high value on hard work and diligence, people with strong work ethics tend to stay focused on the job and leave their personal problems at home. Because they value doing the work right the first time, they take a thorough approach to tasks and apply themselves fully to what they do. People with strong work ethics assume responsibility for any mistakes they do make, fixing the mistakes if they can and willingly accepting the consequences of their actions. They know what management expects of them, and they exercise self-discipline and self-control to meet these expectations. They are proactive, taking the initiative and approaching work tasks positively and enthusiastically.

Nursing students may develop a better grasp of the expectations of the nursing profession by examining the components of a strong work ethic and, through developing a strong work ethic themselves, demonstrating a commitment to their job and to their employer.

Attendance and Punctuality

Attendance is a fundamental requirement to demonstrate commitment to a job. To perform the duties of a job requires showing up for work every day. A key component of attendance is being on time, or **punctual**.

Other employees are required to take on more than their usual workloads to cover for employees who do not come to work. An employee may have a legitimate reason for being absent, but even so, frequent absences increase stress for other employees and decrease productivity. Funding shortages force many healthcare agencies to employ no more employees than are absolutely required. Accordingly, all employees have full workloads that, even under the best of circumstances, require their full commitment and the best of their ability. If employees have to take on some or all of an absent employee’s work, this increases the burden for everyone. Accordingly, every nurse (and nursing student) has the responsibility to be at work and to arrive on time.

Employees who arrive late for work create delays and other inconveniences for their coworkers. A nurse’s failure to be punctual might force the rescheduling of a patient’s procedure and could delay that patient’s (or another’s) diagnosis, treatment, surgery, or discharge from the hospital. That nurse might be late in delivering needed supplies and filing paperwork by its appointed deadline, forcing other people to work overtime to compensate for the delays. Nurses must report to work on time because of the interconnected nature of professional healthcare roles. Being “on time” does not mean arriving at the parking lot at the time work is scheduled to begin; “on time” means that at the start of a nurse’s shift, that nurse is already at work and in place, ready to begin.

It is inevitable for almost everyone to occasionally miss work or arrive late. However, habitual poor attendance and lack of punctuality are performance issues and may be grounds for steps to overcome the problem (**corrective action**) or even terminate employment (**dismissal**).

Professional commitment, then, dictates that nursing students must arrive on time for work every day and be ready to work immediately when the shift starts. To assist with this, nursing students should anticipate potential emergencies, such as a child being sick or a car being in the shop, and set up contingency plans to prepare for them.

A component of forming a good work ethic for nurses is taking steps to protect their own health and safety, such as by getting enough rest, avoiding unnecessary risks, and taking preventive measures such as receiving flu shots.

Another part of maintaining a good work ethic is avoiding excessively long or unscheduled breaks. This involves trying to allow some extra time at the end of every shift in case they are held over. Above all, nurses must never rush out the door the minute the shift ends if that might mean leaving a patient, coworker, visitor, or guest hanging. Staying long enough to complete work or to hand it off properly to the individual who follows is every nurse’s (and nursing student’s) responsibility. Doing so facilitates a smooth transition between shifts and ensures that work in progress is not left for other people to finish.

Reliability and Accountability

Professionalism involves the essential factors of reliability and accountability. From a systems perspective, each nurse must complete the duties of the job appropriately so that others who depend on the nurse can complete their own work. Part of reliability and accountability is following through on commitments—for example, honoring agreements to trade shifts or taking on additional work when someone is absent. Honoring commitments helps the team function properly and builds trust and team cohesion (**Figure 40-3** »). It is also important to take responsibility for the consequences of one’s actions. Professionals do not blame others for their mistakes but instead hold themselves personally accountable.

Professional nurses should refuse work assignments only when the nurse is not qualified or is not prepared to perform the assignment. In either case, the nurse should discuss the situation immediately with the supervisor. Otherwise, the nurse should be ready to complete all assigned tasks,

Figure 40-3 » Nurses are responsible for completing their duties so that other people can complete their own work.

especially because refusal to do so may be regarded as **insubordination** (defiance of authority) and grounds for dismissal.

Nurses act professionally when they avoid judging patients or forcing their own personal beliefs onto patients. When a nurse feels a conflict between an assigned task and the nurse's religious beliefs, morals, or values, it is the nurse's responsibility to bring this conflict to the supervisor's attention and discuss it reasonably. Many employers will allow a nurse to opt out of participation in activities to which the nurse has moral objections, but the nurse should anticipate such conflicts and report them to the employer at the earliest opportunity. For more information, refer to the module on Accountability.

Attitude and Enthusiasm

A positive attitude—an essential professional characteristic for nurses—involves a sense of **optimism**, or a feeling that things will turn out for the best. Professional nurses are typically optimistic, but unfortunately, a negative attitude is a way of life for some people. This negativity expresses itself as **pessimism**, or the belief that the current situation is always bad and may become worse. Pessimists complain about everything and tend to be dissatisfied with what they have. Pessimists do not convey enthusiasm about their work. They rarely smile and often appear unhappy, which, whether the pessimist consciously intends it or not, may spread negativity to their coworkers, undermining morale, teamwork, and cooperative spirit. Pessimism is a dangerous attitude that nurses must guard against, because it erodes trust and confidence. Instead, nurses should convey optimism and enthusiasm about their work, especially to patients and their families. A commitment to positivity contributes to a more pleasant, collegial, and productive work environment.

Arrogance is another negative attitude that can damage a nurse's professionalism. **Arrogance**, or excessive pride and a feeling of superiority, can be an extremely dangerous characteristic in the nurse, as it can lead to a false belief that the nurse is always right and does not need input from others. For example, when the unit begins using a new IV infusion pump, the arrogant nurse does not bother attending the inservice, believing that it is possible to "figure things out" independently. Accurate self-assessment of strengths and weaknesses, as well as acceptance of feedback from others, promotes both safety and growth and is therefore an essential ability for the nurse.

Generational Differences in Work Ethic

Discussions about cultural diversity often focus on differing ethnic, national, or religious perspectives. Studies, including an international research project by Papastavrou et al. (2012), have traced the key differences in cross-cultural perceptions of nursing professionalism (see the module on Culture and Diversity for more information). But at this moment in the United States, the major cultural divide currently impacting nurses' work ethic is the generational gap.

For the first time in American history, four generations of people are working shoulder to shoulder. Research has

shown that generation membership is a key variable in determining behavior (Hendricks & Cope, 2012). Different generations hold different ideals, values, traits, goals, and characteristics, which play a significant role in how employees of one generation relate to those of other generations. These differences can be seen in communication styles, expectations, work styles, values and norms, attitudes about work and life, comfort with technology, views regarding loyalty and authority, and acceptance of change.

The term **generational cohort** refers to people born in the same general time span who share key life experiences, including historical events, public heroes, pastimes, and early work experiences. These common life experiences create cohesiveness in perspectives and attitudes and lead generational cohorts to develop distinct values and work-force patterns. Differences between generations (sometimes called a *generation gap*) can have negative effects in the workplace, causing conflicts and interpersonal tension. Learning to create collegial relationships with people from different generations is a critical skill for nurses who work in multi-generational teams.

While the literature sometimes disagrees on specific years or generational names, there is consistent agreement on the characteristics of each generational cohort. An understanding of the historical influences on each generation, their common life experiences, and the workforce the members entered when first employed is necessary to understand their attitudes and values related to work (see **Table 40-3** >>>).

Different generational styles can lead to workplace conflict. Older nurses may experience considerable conflict over younger nurses' behaviors and may describe younger nurses as arrogant, lacking in commitment, and having a "slacker" attitude. Younger nurses may see themselves as self-reliant rather than arrogant. Older nurses may be dismayed and struggle with a perceived lack of professionalism among their younger colleagues, evidenced by younger nurses' dress, hair styles, piercings, and tattoos. Younger nurses may be disillusioned by older nurses' perceived unwillingness to become technologically competent.

While differences between generations are not new, two significant changes over the past 60 years have forced the current generations in the workforce into more intense interaction. First, the nature of the work itself has shifted. In traditional bureaucratic structures, interactions between generations followed hierarchical lines. People from younger generations traditionally held entry-level positions and reported to people of the older generation in more senior positions. As a result, younger employees took direction from and followed the rules of people who were older. With the advent of continuous quality improvement and shared governance structures, individuals from various "levels" of the organization are now equal members of a team. This arrangement has increased the interaction of employees from different generations.

Second, the transformation from the industrial age to the information age has altered the interactions between people of differing generations. Historically, the most senior members of an organization offered the most reliable information and knowledge. Young nurses relied on their more senior colleagues for instruction and advice when confronted with an unusual diagnosis or a complex patient situation. With

TABLE 40–3 Description of Four Generations in the American Workforce

NOTE: Generational trends exist and everyone is, to some extent, shaped by things that happened in their particular generation; however, nurses should approach each colleague as an individual and should not stereotype based on generation.

Generational Cohort and Their Historical Influences	Life Experiences	Workforce Entered	Work Ethic
Veterans: Born 1925–1944			
Great Depression World War II	News came from newspapers and radio. Long-distance phone calls were rare and expensive. Shopping was mostly done at locally owned stores. Movies were seen only in theaters. Attitude toward children: They should be “seen and not heard.”	End of Depression and war Economic prosperity Emergence of middle class Able to thrive in a nice home on a single income Large, bureaucratic organizations Rules, policies, and procedures plainly outlined	Sacrifice and hard work are rewarded. Seniority is important to advance career. Value loyalty. Respect authority. Like working in teams with designated leaders. Prefer personal forms of communication.
Baby Boomers: Born 1945–1960			
Introduction of television Humans landed on the moon Assassination of President Kennedy Assassination of Dr. Martin Luther King, Jr. Civil rights movement Summer of Love Vietnam War Woodstock Watergate	Grew up in a healthy, flourishing economy. Watched variety shows, movies, and sitcoms in their own home. News became more visual and dramatic. Raised in two-parent households in which father worked and mother was home caretaker. Were members of smaller families.	Emphasis was on freedom to be yourself—the “me” generation. Heroes were those who questioned the status quo. People in positions of power were not to be trusted. Raised to be independent, critical thinkers. Many female college graduates went on to become secretaries, nurses, or teachers because of the perception that these were primarily female professions.	Are workaholics. Embrace sense of professionalism. Self-worth closely tied to work ethic. Question authority. Status quo can be transformed by working together. Desire financial prosperity but long to make a significant contribution with their experience and expertise.
Generation X: Born 1961–1980			
Rising divorce rates Microwaves Video games Computers Space shuttle <i>Challenger</i> disaster Numerous scandals involving high-profile public figures Operation Desert Storm	Lived in two-career households. Many raised in single-parent homes. “Latch key” generation; learned to manage on their own, becoming adept, clever, and resourceful. Allowed to be equal participants in family discussions.	Dramatic downsizing, reengineering, and layoffs seen. Hierarchical structures had begun to flatten, eliminating promotion opportunities for younger workers. Large cohort of baby boomers remained in workforce, filling limited managerial positions. Assume responsibility to keep themselves employable by constantly updating their skills.	Seek challenges. Are self-directed. Expect instant access to information. Desire employment in which they can create balance in work and personal life. Prefer managers to be mentors and coaches. Desire more control over their own schedule.
Millennials (Generation Y): Born 1981–2000			
Established infrastructure (child care, preschool, after-school care) to assist dual-career parents Global generation Internet School shootings Terrorist attack of September 11, 2001 Wars in Afghanistan and Iraq Obama presidency	Mostly children of baby boomers born to older mothers. Life highly structured and scheduled. Parents heavily involved in their upbringing, often chaperoning or coaching extracurricular activities. Accept multiculturalism. Raised enmeshed in digital technology. Mass consumption of pop culture but via the internet.	Economic downturn Drying up of job opportunities in many industries. Belief that education is the key to success. Resurgence of heroism and patriotism. Diversity a given. Renewed sense of interest in contributing to collective good. Volunteering for community service. Joining organizations in record numbers.	Collaborative, open-minded, achievement-oriented. Expectation of daily feedback, high maintenance. Potential to become the highest-producing workforce in history. Personal smart devices a necessity for daily life.

the advent of the information age, young nurses are not as reliant on their older peers, since they can easily access information from around the world on their computers and smartphones. Computerization has not only broken the dependence of younger generations on more senior generations for information, it has also resulted in the unprecedented situation in which the youngest individuals in the workforce are the most expert at a critical skill. Instead of younger nurses turning to their older colleagues for advice, older nurses often depend on their younger peers for guidance in using new technologies.

Members of each generation typically operate as if their own values and expectations are universal. For example, veteran nurses who entered the workforce when success occurred through long-term employment with one organization assume that the same approach will ensure achievement today. They see their younger colleagues' frequent job changes or working as independent agents as unreliability or a lack of commitment. Younger nurses may assume that their older peers who have remained in one place of employment have done so because of failure to take advantage of opportunities. Also, having grown up in a world in which their voice and contributions are expected, younger nurses are often misunderstood when they advise their more senior colleagues who were taught to respect and listen to their elders. An older nurse may see the voiced criticisms of a novice nurse at a staff meeting as disrespectful and therefore discount the younger nurse. From the younger nurse's perspective, speaking up even with limited experience is contributing to the unit.

Learning to develop collegial relationships with people from different generations is a critical skill for nurses who work in multigenerational teams. Working with nurses from different generations offers the opportunity to explore new and different ways of thinking. Rather than focusing on what is "wrong" with another generation, nurses should look for ways to capitalize on each generation's strengths. Nurses of the veteran generation value hard work and respect authority, baby boomers value teamwork, Generation X nurses value self-reliance, and millennial nurses value achievement. In the workplace, a veteran nurse might say, "Do it because I say so," and a baby-boomer nurse might say, "Let's get together and reach a consensus about how to do it." The Generation X staff nurses might say they will do it themselves, and the millennial nurses might not care who does it as long as the work gets done.

Veteran nurses should be valued for the wisdom and organizational history they bring to nursing teams. When technology fails, veteran nurses can assist a unit to quickly shift back to the traditional ways of assessing and caring for patients. Baby boomers should be valued for their clinical and organizational experience and should be used to coach and mentor younger nurses. Generation X nurses should be valued for their innovative ideas and creative approaches to unit issues and problems. They can be important in helping organizations design new approaches to nursing care delivery. Millennial nurses should be valued for their understanding of technology and insights into how it can be used in practice. They can also serve as technology coaches for members of older generational cohorts.

Appreciation of the unique strengths of each generation can decrease interpersonal tension and facilitate personal growth. Nurses who learn to acknowledge and appreciate their colleagues from different backgrounds, including generational backgrounds, have a distinct advantage. Successful teamwork is increasingly required for job satisfaction and the ability to positively affect patient outcomes. This teamwork requirement is reflected in the recent introduction of relationship-based nursing care delivery systems such as the primary nursing model, as discussed in the module on Healthcare Systems. All too frequently, intergenerational interactions lead to conflicts due to lack of appreciation or understanding, or simply to misinterpretation of other perspectives.

Particular attention should be paid to engaging the perspective of younger nurses, as the youngest generation is always at a distinct disadvantage. The existing organizational structure is based on strategies that were used successfully in the past rather than having been designed for the future. Because of their longevity, older generations often dominate in the powerful leadership positions and are more influential when changes are made. These nurses update processes and rewards in a way that makes sense from their generational perspective, often not recognizing that younger nurses might not hold the same perspective and might have a valuable perspective of their own. Incorporating younger nurses' values of participation, access to information, and balance into nursing operations is important. Older nurses need to learn to welcome input from their younger colleagues, encouraging them to use their fresh viewpoints to identify where opportunities exist. Younger nurses need to be taught and learn to value the experience and expertise of more senior nurses who have a wealth of lived experiences to share.

The best teams use the contributions of each generation's skill set and strengths. The hardworking, loyal veterans; the idealist, passionate baby boomers; the techno-literate, adaptable Generation Xers; and the young, optimistic millennials can come together in a powerful network of nurses with a remarkable ability to support each other and maximize each nurse's contribution to patient care (**Figure 40-4** >>).

- Additional review material

REFLECT Apply Your Knowledge

How would you respond in each of the following situations?

1. You were out with friends until very late last night and were scheduled to report for work this morning at 7 a.m. You arrive on time, but you know that your coworkers won't get there for another half hour. You have just enough time for a quick run to the corner coffee shop before your coworkers arrive.
2. You promised your coworkers that you would work the day shift on Thanksgiving so they could be home with their families. Two days before the holiday, an old friend from out of town calls to say that he would like you to be his guest for lunch on Thanksgiving Day.
3. You have an appointment with your supervisor next week to review the results of your annual performance evaluation. You overhear one of your teammates telling another individual that she gave you a low score on your 360-degree feedback evaluation because you refused to trade shifts with her over the Easter weekend.
4. Your shift ends in 30 minutes, and you have about 30 minutes of work left to do, but you have not been able to take your afternoon break yet.
5. One of your neighbors is admitted to the unit where you work. A member of your family calls to tell you that he has heard a rumor that the neighbor has a communicable disease. Because you work on the unit and have access to patient records, your family member asks you to find out whether the rumor is true.
6. A new piece of equipment has been installed in your department, but you missed the in-service session in which everyone was trained in how to operate it. Today a procedure is to be done using this equipment, and it is your responsibility to use it.
7. A coworker invites you to a party. When you arrive, you notice three other people you work with complaining about low wages and telling a group of strangers that one of the surgeons at your hospital made a mistake in surgery last week and lied to the patient's family to try to cover it up.

Teaching is a system of activities designed to produce learning. **L**earning is a change in human disposition or capability that persists and cannot be solely accounted for by growth. Broadly speaking, learning is represented by a change in behavior; in other words, the learner is able to apply or demonstrate what is learned. Some additional attributes of learning are described in **Box 41-1** >>.

Box 41-1

Attributes of Learning

Learning is:

- An experience that occurs within the learner
- The discovery of the personal meaning and relevance of ideas
- A consequence of experience
- A collaborative and cooperative process
- An evolutionary process that builds on past learning and experiences
- A process that is both intellectual and emotional

The teaching-learning process involves dynamic interaction between teacher and learner. Each participant in the process communicates information, emotions, perceptions, and attitudes to the other person. Because nurses constantly gather information from and provide information to patients and other individuals, they require a clear understanding of the roles of teacher and learner alike.

This concept takes an in-depth look at the teaching-learning process and the nurse's responsibility as a patient and family educator. In doing so, it examines major domains and theories of learning as well as factors that affect an individual's ability to learn. The concept concludes with a discussion of ways in which nurses can use their knowledge of the teaching-learning process to design more successful patient and family education activities.

Nurses as Teachers and Learners

Nurses as Teachers

The American Nurses Association (ANA) Standards of Practice for Registered Nurses (2010) identify teaching as one of

the many roles of the professional nurse. Although nurses teach a variety of learners in many different settings, most nurses primarily teach patients and their families. Examples of patient and family teaching include instruction about how to perform self-care; how to take medications and recognize their side effects; and how to perform prescribed treatments (e.g., deep breathing and coughing). Although most teaching is done directly with patients, family members or caregivers may also be instructed in care of the patient. This is especially important for those patients who have difficulty performing self-care. For example, parents who need to give medication to their children must be instructed in the proper administration of that medication. Patients with diabetes who have visual impairments may need assistance when administering insulin or when assessing their feet and lower extremities for skin breakdown. When teaching patients about diet, it is important to include the person who purchases and prepares the food.

In addition to teaching patients and their families, nurses teach professional colleagues and other healthcare personnel in academic settings such as vocational schools, colleges, and universities, as well as in healthcare facilities such as hospitals or nursing homes. Teaching occurs through a variety of formal and informal encounters, including mentoring, continuing education classes, and clinical experiences for nursing students. **Box 41-2** » describes the mentoring relationship among nurses.

A number of factors affect the ways in which nurses teach patients and others in the healthcare system. Federal and state regulations influence what content should be taught and indicate what documentation is required of nursing schools, certifying agencies, and agencies employing and training nurses and other healthcare professionals. Nurses who provide patient education do so for individuals

who vary in age, cultural and socioeconomic background, primary language, and previous knowledge and experience. Information is constantly changing as new research becomes available. Today's resources are numerous and readily available through the internet. These factors combine to make providing patients with accurate, current information a challenge for nurses.

Nurses as Learners

The field of nursing requires that its members be not only teachers, but also learners. Before entering the profession, all aspiring nurses must complete formal education programs that teach them effective beginning nursing skills. Furthermore, because changes occur quickly and often in health-care, nurses must continue learning to keep their knowledge current. The ANA Standards of Professional Performance recognize this (Standard 8, Education), and each state's board of nursing outlines continuing education requirements designed to increase nurses' knowledge and skill (ANA, 2010).

To help nurses maintain their licenses and ensure quality of care, many employers provide continuing education programs at the work site, although some nurses may need to travel to specialized centers to gain advanced skills. In addition, many nurses return to school to obtain advanced degrees in nursing and other health-related disciplines.

Concepts Related to Teaching and Learning

The concepts of development, communication, health, wellness, and illness are directly related to the concepts of teaching and learning. Nurses must understand various theories of psychosocial development and basic principles of

Box 41-2 Mentoring

Mentoring is an important career development tool for nurses in any setting or specialty. **Mentors** are experienced nurses who coach, advise, and support the personal and professional growth of a less-experienced or novice mentee or protégé in a professional relationship by discussing mutual goals and providing accountability (Hnatiuk, 2012). Fortunately, modern technology provides more opportunities for mentoring via the internet and other rapid communication methods when the protégé is not physically in the same location as the mentor.

Often, the mentor relationship is one of teacher–learner. The mentor instructs the protégé in her expected role, introduces the protégé to individuals important to the achievement of her goals, helps the protégé evaluate new ideas, and challenges the protégé to advance her professional practice. Mentor programs are important for both student nurses and newly graduated nurses when transitioning from the role of a student into the role of a professional nurse. Mentoring is also important for professional development in nursing administration and nursing education and when nurses enter a new position (Hnatiuk, 2012; McCallum, Lamont, & Kerr, 2016; Rush et al., 2012).

Nurse mentor programs also benefit the nursing profession as a whole. Transitioning to practice can affect a new nurse's job

satisfaction, job retention, and stress levels, as well as patient safety (National Council of State Boards of Nursing [NCSBN], 2016; Spector et al., 2015). Hospitals with an evidence-based, structured transition-to-practice program have higher job satisfaction, retention, and competency levels. They also have decreased stress and patient care errors among new graduate nurses compared to hospitals without transition-to-practice programs (Spector et al., 2015).

The mentoring relationship requires work and time from both the mentor and protégé. Some mentoring relationships have negative effects, including power struggles, intimidation, and loyalty issues. Nurses should recognize their individual strengths and encourage excellence in one another rather than feeling intimidated by each other. Employees must feel safe in their workplace, and a commitment to improving intrapersonal and interpersonal communication among nurses should provide a safe learning environment and encourage growth. Mindful creation of collaborative work environments is an essential task of nurse leaders (Warshawsky, Havens, & Knafl, 2012). Such environments help nurses unite and support each other, which helps ensure safety and excellence in nursing practice.

communication to create effective teaching plans and transmit information appropriate to each patient's level of understanding. Combining psychologic theories such as Erik Erikson's stages of psychosocial development, Jean Piaget's phases of cognitive development, and John B. Watson's behaviorism theory will provide direction and explanations for a fundamental understanding of mental, emotional, and social development during the lifespan. Similarly, cultural competency has become increasingly relevant for nurses providing teaching and therapeutic communication to diverse populations and in diverse settings. Educational materials and care plans must be patient specific and written after all aspects of a patient's cultural, mental, and physical status are assessed.

Knowledge of basic principles of teaching and learning is crucial because nurses empower individuals to lead healthier lives. Teaching and promoting general health principles such as good nutrition practices, illness and infection prevention, and safety measures are among the primary roles and responsibilities of nurses as patient advocates and, in some cases, professional educators of colleagues. Education empowers individuals to be active participants in their healthcare and promotes individual recovery, self-control, and personal responsibility for health and well-being. Some, but not all, of the concepts that are integral to teaching and learning are outlined in the Concepts Related to Teaching and Learning feature. They are presented in alphabetical order.

Concepts Related to Teaching and Learning

CONCEPT	RELATIONSHIP TO TEACHING AND LEARNING	NURSING IMPLICATIONS
Communication	Teaching and learning processes require nurses and patients alike to engage in verbal, nonverbal, and written communication.	<ul style="list-style-type: none"> ■ Use various elements of verbal communication—including pace, intonation, clarity, credibility, timing, relevance, and humor—in ways that are appropriate and help promote desired learning outcomes. ■ Effectively employ different elements of nonverbal communication, including posture, appearance, facial expressions, and gestures. ■ Create, distribute, and recommend written communication items (e.g., handouts, computer programs, mobile device apps) that are reflective of patients' literacy levels.
Culture and Diversity	Understanding and appreciating cultural diversity will encourage and promote trusting, interactive communication in patient care and interprofessional relationships.	<ul style="list-style-type: none"> ■ Evaluate personal attitudes and beliefs regarding cultural diversity. ■ Recognize and consider patients' cultural background when planning care. ■ Coordinate interprofessional participation for resources such as interpreters or social and faith-based services to meet patients' culture-specific needs.
Development	As children develop, their learning abilities become more complex. As adults age, their vision, hearing, and motor function may become impaired. They may also experience declines in cognitive functioning.	<ul style="list-style-type: none"> ■ Assess patient's age and developmental stage. ■ Use teaching methods appropriate to the patient's age and level of development. ■ Be aware that age does not always indicate specific developmental characteristics.
Health, Wellness, Illness, and Injury	Knowledge empowers individuals to make lifestyle choices that promote health and may prevent illness and injury.	<ul style="list-style-type: none"> ■ Educate patients to be effective healthcare consumers. ■ Reinforce healthy patient behaviors. ■ Guide patients in problem solving health-related issues.
Nutrition	Understanding basic nutritional requirements and food preparation guidelines can help individuals promote health, prevent illness, and manage existing disease processes.	<ul style="list-style-type: none"> ■ Promote the importance of a balanced diet for disease prevention. ■ Provide information and teaching on specific diets related to disease management. ■ Provide referrals to a nutritionist or dietitian.
Safety	Knowledge of safe practices can help both patients and healthcare personnel avoid accidents and injury.	<ul style="list-style-type: none"> ■ Assess patient's level of safety and risk for injury related to the environment. ■ Evaluate safety risks related to patient's cognitive and/or physical development. ■ Provide information about and teach basic safety precautions.

The Art of Teaching

Teaching is a system of activities intentionally designed to produce specific learning. It is a goal-directed activity that results in improved learning for the learner. Teaching is more than giving information; the art of teaching lies in creating a learning environment that helps the learner cultivate knowledge, skills, and an internal desire to change some aspect of his or her life. Just as care plans are patient specific, teaching plans should also be specific to each learner. This means the nurse must carefully evaluate and consider the learning capabilities and preferences of each individual, remembering that even people within the same cultural or social group will have their own distinct learning styles.

Nurses should also recognize when patients misinterpret health teaching, or when the patient's health education needs are beyond the nurse's scope of practice or specialty knowledge base. Quality teaching requires knowledge, an understanding of the learning process, good judgment, and a sense of intuition. Most importantly, it encourages learners to be actively involved and accountable in the learning process. For a more complete description of the characteristics of effective teaching, refer to **Box 41-3** >>.

SAFETY ALERT Safe, effective teaching relies on the nurse's knowledge of the subject matter. Inaccurate or incomplete knowledge may result in the patient receiving incorrect information about a condition or treatment and may compromise the patient's safety.

The relationship between teacher and learner is essentially one of trust and respect. The learner trusts that the teacher has the knowledge and skill to teach, and the teacher respects the learner's ability to attain the recognized goals. Once a nurse starts to instruct a patient or other learner, it is important that the teaching process continue until the

participants achieve the mutually agreed-upon learning goals, change the goals, or decide that the goals cannot be met.

As teachers, nurses must understand a number of learning theories. By understanding how people learn and the factors that impact learning, nurses can develop more successful teaching plans for individual patients and their families, as well as for various groups of learners.

Aspects of Learning

Individuals have a variety of learning needs. A **learning need** is a desire or requirement to know something that is currently unknown to the learner. Learning needs may include new knowledge or information, a new or different skill or physical ability, a new behavior, or a need to change an old behavior.

One important aspect of learning is compliance, or the individual's desire to learn and to act on that learning. In the healthcare context, **compliance** refers to the extent to which an individual's behavior coincides with medical or health advice. Compliance is best illustrated when the individual accepts the need to learn, then follows through with appropriate actions that reflect the learning. For example, a patient who is diagnosed with diabetes would be compliant if he willingly learned about the recommended special diet, then followed that diet. However, many people view the term *compliance* negatively because it implies the learner is submissive, and submission conflicts with the learner's right to make his or her own healthcare decisions. At the same time, some professionals are too quick to label a patient as non-compliant. It is important to determine why a patient is not following a recommended course of action before applying this label. For example, a patient may have intended to comply with a prescription regimen but was unable to do so because he could not afford the cost of the medications.

A related aspect of learning described in healthcare literature is **adherence**, or attachment to a prescribed regimen. Modern healthcare promotes and encourages patients to be committed, active participants in maintaining personal health and wellness. According to Maningat, Gordon, and Breslow (2013), "Compliance suggests that the patient is passively following the physician's orders, while adherence acknowledges that the patient is part of the decision-making process" (p. 2). Adherence identifies the level of a patient's behavioral patterns in response to mutually agreed-upon healthcare providers' teaching and treatment recommendations (Centers for Disease Control and Prevention [CDC], 2013). When evaluating responses and results of treatment plans, nurses may use the terms *adherence* and *compliance* interchangeably. Although both terms convey the same general concept, adherence has more positive connotations and emphasizes the collaborative nature of the patient-provider relationship (van den Bemt, Zwikker, & van den Ende, 2012). The term *adherence* also recognizes that factors other than patient willingness to comply (e.g., financial considerations) may affect the treatment process.

Learning Theories

A number of different theories can help nurses understand the ways in which people learn. Adult learning theory, behaviorist theory, cognitive theory, social learning theory, and

Box 41-3

Characteristics of Effective Teaching

Effective Teaching

- Holds the learner's interest.
- Involves the learner in the learning process, and creates a partnership between the learner and the teacher.
- Fosters a positive self-concept in the learner such that he or she believes that learning is possible and probable.
- Is appropriate for the learner's age, condition, and abilities.
- Sets realistic goals directed at helping learners meet their objectives.
- Supports the learner with optimistic, positive reinforcement and feedback.
- Uses accurate and current evidence-based information from reliable sources.
- Uses several methods of teaching to accommodate a variety of learning styles, and provides learning opportunities through hearing, seeing, and doing.
- Uses methods to evaluate learning.
- Is cost effective (i.e., the cost of the nurse's time spent teaching is less than the cost of treating health problems that occur when patients do not follow recommended treatments, fail to take medications correctly, or do not adapt their lifestyle to changing health needs).

TABLE 41–1 Major Learning Theories and Their Implications for the Teaching Process

Learning Theory	Summary	Implications for Teaching
Adult learning theory	Adult learners differ from child learners in fundamental ways. In particular, adults: <ul style="list-style-type: none"> ■ Need to know why they should learn something. ■ Prefer that others treat them as capable of self-direction. ■ Have accumulated life experiences that can enhance their current learning. ■ Are often ready to learn what they must know in order to take care of themselves. 	When providing teaching to adult patients or caregivers, communicate how and/or why information is important and useful. Respect the learner as an independent, competent adult. Identify previous experiences and help the learner scaffold or incorporate new information with previous experiences.
Behaviorist theory	Learning occurs when an individual's response to a stimulus is either positively or negatively reinforced. It is possible to change an individual's behavior by either altering the stimulus condition or altering what happens after the individual responds to the stimulus. Providing positive reinforcement , or a pleasant experience such as praise and encouragement, is especially useful in fostering repetition of an action.	Provide praise or encouragement with each attempt or at each phase of the learning process. Allow sufficient time for the learner to practice new skills (e.g., return demonstrations). Consider environmental influences that affect the learning process.
Cognitive theory	Learning involves three mental processes that can occur sequentially or simultaneously: (1) acquiring information, (2) processing the information, and (3) using the information. An individual's capacity to learn is shaped by his or her developmental level as well as by the social, emotional, and physical contexts in which learning takes place. Learning occurs across three primary domains: the cognitive (or "thinking") domain, the affective (or "feeling") domain, and the psychomotor (or "skill") domain.	Develop appropriate strategies to meet each learner's unique learning style and preferences. Assess each learner's developmental stage and emotional readiness to learn, then adapt teaching strategies to the learner's level. Select behavioral objectives and teaching strategies that encompass the cognitive, affective, and psychomotor domains of learning.
Constructivist theory	Learning is a developmental process constructed from individual experiences. Knowledge acquisition is the ongoing assimilation and accommodation of new experiences and interpretations. Cooperative learning and problem-solving in collaboration with others promote learning.	Acknowledge the importance of and build on the learner's prior learning experiences. Encourage the learner to engage with the nurse and others during the learning process.
Social learning theory	Learning primarily results from instruction and observational learning , or the process of acquiring new skills or altering old behaviors by watching other people. This process focuses on imitation and modeling . The cognitive aspect of social learning theory suggests that an individual's beliefs, perceptions, and cognitive competencies influence the way in which the individual interacts with the environment.	By modeling how to perform skills (such as changing a wound dressing) and asking for repeat demonstrations until the patient can perform the skill satisfactorily, the nurse provides an opportunity for imitation and modeling.

humanistic learning theory are among the theories most commonly used by nurses when teaching individuals and groups of learners. Additional concepts that the nurse should keep in mind when formulating teaching plans include the theories of categorization and constructivism. **Table 41–1** » provides a brief description of these theories and highlights some ways nurses can apply each theory in the teaching process.

In addition to the learning theories discussed in the table, nurses should understand the **theory of multiple intelligences**. This theory was presented by researcher Howard Gardner and is based on observations of the ways in which stroke damage can impact one area of the brain while leaving other areas of mental functioning intact. Initially, Gardner (1983) cited seven intelligences:

1. Linguistic
2. Musical/rhythmic (music)
3. Logical/mathematical
4. Spatial (visual)
5. Kinesthetic/movement (body)
6. Personal
7. Symbols as intellectual strengths or ways of knowing

Gardner has since added an eighth intelligence, naturalist intelligence, which is associated with recognition of environmental elements and patterns (Candela, 2012).

Gardner's work is one of several theories that challenge the notion that intelligence is static and is solely based on the learner's intelligence quotient, or IQ, which is a score derived from standardized tests. Another important theory that disputes the concept of IQ was put forth by researcher Daniel Goleman. Goleman (1995) proposed that **emotional intelligence**—or EQ—is as relevant to learning and success as IQ, or even more so. EQ measures individuals' abilities to differentiate between their own thoughts and feelings, recognize the thoughts and feelings of others, and show discernment when using emotions to influence decisions.

It is important for nurses to understand the focus and limitations of the various learning theories, as well as Gardner's and Goleman's theories. Intelligence levels are unique and specific to every person, and individuals can exhibit one or more intelligences at higher operant levels than the others. By knowing the various theories, the nurse can select the most appropriate theory or theories when developing a teaching plan for a specific patient.

Clinical Example A

Patrick Johnson is a 60-year-old man who owns a small business. Mr. Johnson underwent coronary bypass surgery (CABG) 3 days ago after experiencing a myocardial infarction at his retail store. He is scheduled for hospital discharge within the next 48 hours. The nurse responsible for Mr. Johnson's care and discharge planning notes that the healthcare provider has ordered several new medications, as well as dietary restrictions and follow-up appointments.

Mr. Johnson is used to working 7 days per week. He lives with his 56-year-old wife, who occasionally helps at the store but also works as a part-time substitute teacher. The Johnsons have two grown children who are married and reside out of state. Mr. Johnson states that he is very worried that his business (and therefore his income) will decline due to his recent health problems and potential lifestyle changes.

Critical Thinking Questions

1. Discuss the impact of Mr. Johnson's recent health impairment and stated concerns on his ability to "learn," and apply information based on the cognitive and psychomotor domains of learning. What factors might hinder Mr. Johnson's ability to learn? Do any real and/or potential factors exist to promote his learning?
2. Is teaching a priority of care for Mr. Johnson at this time? Why or why not?

Factors Affecting Learning

Many factors can facilitate or inhibit a patient's ability to learn, including stress level, effects of medication, fatigue, or pain. The nurse should be aware of these factors, particularly when available teaching time is limited.

Factors That Facilitate Learning

A number of factors promote learning. Although these factors are common to all people, how they promote learning in the individual learner will vary. What motivates one individual to learn, for example, may not motivate another individual at all.

- **Motivation:** Motivation to learn is personal and affects how much an individual learns. It can also influence the rate of learning. Motivation must be identified and experienced by the patient—the nurse's recognition of a need is not sufficient to motivate a patient, although the nurse can help the patient identify and embrace the need. Furthermore, the nurse can help persuade support people that a need exists by providing information and/or reminding the patient how his behaviors affect the people around him. For example, a man who has smoked for 20 years may not embrace the need to quit for the benefit of his own health. However, if the nurse provides patient education that includes the dangers of secondhand smoke, especially to young children, the man may recognize the need to quit smoking for the benefit of a child or grandchild.
- **Readiness:** Readiness to learn refers to an individual's demonstration of behaviors or cues that reflect her motivation to learn at a specific time. Readiness reflects not only the desire or willingness to learn, but also the ability to learn. The nurse's role is often to encourage the development of readiness. For example, a patient may want to learn self-care during a dressing change, but if the patient is experiencing pain or discomfort, she may not be able to

learn. In this case, the nurse can provide pain medication to make the patient more comfortable and ready to learn.

- **Active Involvement:** When a learner is actively involved in the process of learning, learning becomes more meaningful. If the learner actively participates in planning and discussion, he will learn more quickly and retain more information. Active learning promotes critical thinking, enabling learners to solve problems more effectively. Patients who are actively involved in learning about their healthcare may be more able to apply that learning to their own situation. For example, patients who are actively involved in learning about their therapeutic diets may be more able to apply the principles being taught to their cultural food preferences and usual eating habits. Passive learning, such as listening to a lecture or watching a film, does not foster optimal learning.
- **Relevance:** Patients learn more quickly and retain more information when what they are learning is personally relevant to them. It also helps when they can connect the new knowledge to things they already know or have experienced. For example, if a patient is diagnosed with hypertension, is overweight, and has symptoms of headaches and fatigue, he is more likely to understand the need to lose weight if he remembers having more energy when he weighed less. The nurse needs to validate the relevance of learning with the patient throughout the learning process.
- **Feedback:** Feedback is information regarding an individual's performance in relation to a desired goal. To be effective, feedback must be meaningful to the learner. Nurses can provide either positive or negative feedback when teaching patients. Positive feedback or reinforcement may include praise, positively worded corrections, and gently worded suggestions of alternative methods, all of which encourage patients to continue engaging in a desired behavior. In contrast, negative feedback, including ridicule, anger, or sarcasm, can lead people to withdraw from learning. Such feedback, viewed as a type of punishment, may cause the patient to avoid the teacher in order to avoid punishment.
- **Nonjudgmental Support:** People learn best when they believe they are accepted and will not be judged. The individual who expects to be judged as a "poor" or "good" patient will not learn as well as the individual who feels no such threat. Once learners have succeeded in accomplishing a task or understanding a concept, they gain self-confidence in their ability to learn. This confidence reduces their anxiety about failure and can motivate greater learning.
For example, when a nurse cares for a patient who did not graduate from high school, she should independently assess the patient's ability to learn and not make a judgment about the patient's ability based on education level. Completing high school is an indication of the patient's level of formal education, not an indication of the patient's intellect or ability to learn. The patient may be highly intelligent and self-taught, but the nurse will not know this unless she begins by assessing the patient's ability to learn.
- **Information That Proceeds from Simple to Complex:** Learning is facilitated by material that is logically organized and proceeds from the simple to the complex. Such organization enables the learner to comprehend new

information, assimilate it with previous learning, and form new understandings. Of course, *simple* and *complex* are relative terms, depending on the level at which a person is learning. What is simple for one person may be complex for another.

- **Repetition:** Repetition of key concepts and facts facilitates retention of newly learned material. Similarly, practicing psychomotor skills (particularly with feedback from the nurse) improves an individual's performance of those skills and facilitates their transfer to other settings.
- **Timing:** People retain information and psychomotor skills best when there is a short time interval between learning and using what they have learned; the longer the time interval, the easier it is for people to forget new skills and information. For example, a patient who is only shown literature and videos about administering insulin but is not permitted to administer his own insulin until discharge from the hospital is unlikely to remember what he learned. However, giving his own injections while in the hospital (and with feedback from the nurse) enhances the patient's learning.
- **Environment:** An optimal learning environment facilitates learning by reducing distractions and providing physical and psychologic comfort. It has adequate lighting that is free from glare, a comfortable room temperature, and good ventilation. Most students know what it is like to try to learn in a hot, stuffy room; the consequent drowsiness interferes with concentration. Noise can also distract the student and interfere with listening and thinking. To facilitate learning in a hospital setting, nurses should choose a time when no visitors are present and interruptions are unlikely.

In some situations, privacy during the learning process is essential. For example, when a patient is learning to change a colostomy bag, the presence of others can be embarrassing and thus interfere with learning. However, when a patient is particularly anxious, having a support person present may give the patient confidence.

Clinical Example B

Angela Simpson, a 22-year-old woman, recently gave birth to her first child, and she is eager to learn how to safely care for her newborn. Angela believes that babies should sleep on their stomachs (prone position), and she has grown up observing family members, including her own mother, use this position with her younger siblings at naps and bedtime. As Angela's nurse, you know that evidence-based research discourages this tradition, because stomach sleeping is linked to an increased risk for sudden infant death syndrome (SIDS). You also note that Angela is currently staying with her mother (the baby's grandmother), who is actively involved in caring for her grandchildren.

Critical Thinking Questions

When developing a plan for teaching infant care to this mother:

1. What essential information would you want Ms. Simpson to learn?
2. How could you assess Ms. Simpson's motivation to apply this information?
3. In what setting would Ms. Simpson be most likely to learn and retain the information?

Factors That Inhibit Learning

Many factors can inhibit patient learning. Some of the most common barriers to learning are described in **Table 41-2** >>. Several of these barriers are described below:

- **Emotions:** Emotions such as fear, anger, and depression can impede learning. Similarly, high levels of anxiety can result in agitation and an inability to focus or concentrate, thereby also inhibiting learning. Patients or families who are experiencing extreme emotional states may not hear spoken words or may retain only part of the communication. However, emotional responses such as fear and anxiety decrease with information that relieves uncertainty. In some cases, patients (and perhaps even families) who are extremely distraught may be prescribed medications in order to reduce their anxiety and put them in an emotional state in which learning can occur.
- **Physiologic Events:** Physiologic events such as critical illness, pain, or sensory deficits inhibit learning. Because the patient cannot concentrate and apply energy to learning, the learning process itself is impaired. For this reason, the nurse should try to reduce the patient's physiologic barriers to learning as much as possible before teaching. For patients who are experiencing a physiologic event, analgesics and rest before teaching may be helpful.
- **Cultural Aspects:** Cultural barriers to learning arise when the patient's language, beliefs, or values are different from those of the healthcare team. The most obvious barrier is language: A patient who does not understand the nurse's language may learn very little. Another impediment to learning is differences between the values held by the patient and those held by the healthcare team. Western medicine also may conflict with a patient's cultural healing beliefs and practices. To be effective, nurses must be culturally competent; otherwise, patients may be partially or totally noncompliant with recommended treatments.
- **Psychomotor Ability:** Nurses should be aware of patients' psychomotor ability when planning teaching. Psychomotor skills can be affected by health. For example, an older patient who has severe osteoarthritis of the hands may not be able to wrap a bandage. The following physical abilities are especially important for learning psychomotor skills:
 - **Muscle strength.** Patients must possess the strength necessary to carry out a new skill. For example, an older patient who cannot rise from a chair because of insufficient leg and muscle strength cannot be expected to learn to lift herself out of a bathtub.
 - **Motor coordination.** Gross motor coordination is required for movements such as walking, whereas fine motor coordination is needed for tasks like eating with utensils. For example, a patient who has advanced amyotrophic lateral sclerosis involving the lower limbs will probably be unable to use a walker.
 - **Energy.** Patients need energy for most psychomotor skills—and learning these skills requires even more energy. People who are ill or older often have limited energy resources. Therefore, nurses should schedule the teaching and practice of new skills for times when patients' energy levels are at their peak.

TABLE 41–2 Barriers to Learning

Barrier	Explanation	Nursing Implications
Acute illness	Patient requires all resources and energy to cope with illness.	Defer teaching until patient is less ill.
Pain	Pain decreases the ability to concentrate.	Conduct pain assessment before teaching.
Prognosis	Patient can be preoccupied with illness and unable to concentrate on new information.	Defer teaching to a better time.
Biorhythms	Mental and physical performances have a circadian rhythm.	Adapt time of teaching to suit patient's circadian rhythms. For example, plan a teaching session during the part of the day when the patient is most alert.
Emotions (e.g., anxiety, denial, depression, or grief)	Emotions require energy and distract from learning.	Deal with emotions and possible misinformation prior to providing patient teaching.
Language	Patient may not be fluent in the nurse's language.	Obtain the services of an interpreter or nurse with appropriate language skills.
Older adults	Vision, hearing, and motor control can be impaired in older adults.	Consider possible sensory and motor deficits, and adapt the teaching plan as needed.
Children	Children have a shorter attention span and different vocabulary than adult patients.	Plan shorter and more active learning episodes.
Culture/religion	A patient's culture and/or religion may place restrictions on certain types of knowledge (e.g., birth control information).	Assess the patient's cultural and/or religious needs when planning learning activities.
Physical disability	Visual, hearing, sensory, or motor impairments may interfere with a patient's ability to learn.	Plan teaching activities appropriate to the learner's physical abilities. For example, provide audio learning tools for a patient who is blind or large-print materials for a patient whose vision is impaired.
Mental disability	Impaired cognitive ability may affect a patient's capacity for learning.	Assess patient's capacity for learning. Plan teaching activities to complement the patient's ability while also planning more complex learning for the patient's caregivers.

- **Sensory acuity.** Sight is vital to the learning and completion of many psychomotor tasks, such as walking with crutches, changing a dressing, or drawing a medication into a syringe. Thus, patients who have a visual impairment often need the assistance of a support person to carry out such tasks.

Clinical Example C

Margaret Kim, a 36-year-old woman, is being transferred from the hospital to a long-term care facility to recover following a motor vehicle crash. Ms. Kim sustained multiple fractures resulting in partial paralysis on her right side. She and the nurse planned a learning session at 1:00 p.m. to discuss wound care and medications for post-hospitalization treatment and care. At 1:00 p.m., the nurse comes to Ms. Kim's room with supplies and handouts to help Ms. Kim learn. The nurse finds Ms. Kim crying.

Critical Thinking Questions

1. What actions should the nurse take at this time?
2. Can learning take place? Why or why not?
3. Discuss strategies that the nurse could use to enhance Ms. Kim's readiness to learn.

Lifespan Considerations

As individuals progress from infancy to older adulthood, their capacity to learn changes in many different ways. To ensure that their efforts to educate patients are as successful as possible, nurses must carefully assess each patient's level of development before creating a teaching plan. Generally speaking, patients within certain age groups tend to be at

similar levels of development, and they often face similar physical, cognitive, and psychosocial factors that impact learning. A comprehensive discussion of these levels and factors and how they affect the nursing process (including patient teaching efforts) is provided in the module on Development. In addition, the following sections highlight some of the most important points to keep in mind when planning and delivering teaching to patients at various stages throughout the lifespan.

Teaching Children

Children are constantly developing new cognitive and motor skills and becoming increasingly purposeful when interacting with their environment. Therefore, when developing a teaching plan for a pediatric patient, the nurse must first assess the child's level of development. Teaching plans for patients in this age group typically focus on primary healthcare, health promotion, and illness/injury prevention. In most cases, the teaching plan should be directed toward the parent or primary caregiver; however, the nurse must include the child in the teaching and provide basic instructions at the child's level of understanding.

To ensure successful outcomes, seek to establish trust by addressing the child by name. Be sure all teaching interventions are implemented in a safe environment using a calm approach, and take care to address any concerns or fears of the child or parent/caregiver. Allow time for questions and practice if the teaching involves patient or caregiver performance of a skill or task. When appropriate, use props to demonstrate treatment procedures

Source: Vgajic/iStock/Getty Images.

Figure 41-1 >> This preschooler is holding a teddy bear that the nurse “examined” first to show the child what to expect.

(**Figure 41-1** >>). Always provide feedback, praise, and encouragement; evaluate the effectiveness of the teaching/learning experience; reinforce teaching as needed; and document the intervention (Ball et al., 2017). See the Patient Teaching feature for tools to use when teaching children.

Teaching Adolescents

Adolescents experience many cognitive, moral, and physical changes as part of the transition from childhood to adulthood. Interpersonal communication, development of trusting relationships, and increased independence are of primary importance to patients in this age group. Health alterations can deeply affect personal identity, including feelings of well-being and perceptions of body image, and may carry long-term effects.

Before constructing a teaching plan for an adolescent patient, assess the patient’s level of development and independence from parents and caregivers. During the teaching session, acknowledge and show respect for the patient’s fears and feelings, and strive to provide a calm environment. Involving adolescents in the teaching effort facilitates a trusting relationship between the nurse and the patient and is essential for successful teaching. Teaching and health promotion for adolescent patients should focus on safety, consequences, and personal responsibility due to environmental influences that may involve peer pressure and risk-taking behavior. As with younger patients, allow time for questions and practice if teaching involves performance of a skill or task, and provide feedback, praise, and encouragement. Always evaluate the effectiveness of the learning and teaching, reinforce teaching as needed, and document the intervention (**Figure 41-3** >>).

Teaching Adults

An individual’s critical thinking skills, cognitive development, and learning styles or preferences are influenced by personal experience and may change over a lifetime. Accordingly, before teaching, the nurse must seek to determine the adult patient’s unique learning preferences, even if the nurse has worked with the patient in the past. In addition,

Patient Teaching

Tools for Teaching Children

- **Visits.** Have children visit the hospital and treatment rooms so they can see people dressed in uniforms, scrub suits, and protective gear.
- **Dress-up.** Have children touch and dress up in the clothing they will see and wear (**Figure 41-2** >>).
- **Coloring books.** Use coloring books to prepare children for treatments, surgery, or hospitalization. These books should show what the rooms, people, and equipment will look like.
- **Storybooks.** Storybooks describe how the child will feel, what will be done, and what the place will look like. Parents can read these stories to children several times before the experience. Younger children like this repetition.
- **Dolls.** To give children a sense of mastery of their situation, have them practice procedures that they will later experience on dolls or teddy bears. Custom dolls are often available for inserting tubes and giving injections.
- **Puppet play.** Puppets can be used in role-play situations to provide information and show the child what an experience will be like. Use of puppets can help the child express emotions.
- **Health fairs.** Health fairs can educate children about their bodies and ways to stay healthy. Fairs can focus on high-risk problems children face, such as accident prevention, poison control, and other topics identified in the community as a concern.

Figure 41-3 » An adolescent with diabetes is learning how to check his blood sugar. The nurse will next provide an opportunity for the patient to try it on his own.

gathering subjective and objective data regarding the patient's personal demands, responsibilities, educational level, cultural influences, and motivation to learn is essential to setting realistic teaching goals and preparing the patient for success.

Because teaching is one of the most critical nursing interventions, a nurse's self-awareness of his or her personal learning style may be helpful when developing individualized patient teaching plans. Adult learners have a "need to know," so it is important for the nurse to allow time for questions and practice if teaching involves return demonstrations of skills or tasks (**Figure 41-4** »). Providing feedback, reassurance, and support promotes a positive learning experience.

Nurses should also emphasize and promote the importance of positive health practices and actively involve patients in their care during patient teaching. However, it is imperative for nurses to remember that adult patients are responsible for their behaviors, and nurses cannot control responses or change patients' habits. Providing knowledge and awareness are the primary goals.

SAFETY ALERT Patient teaching documents are often written above the reading level of the average adult, increasing the potential for negative patient outcomes. Many formulas are available for assessing the reading level of written material, and most word processing programs have a feature that calculates readability. Materials should target a fifth- or sixth-grade level.

Teaching Older Adults

Teaching for older patients primarily focuses on health promotion, disease management, and illness/injury prevention. Many older adults have chronic illnesses that require various medications and therapies, so teaching with regard to these treatments is essential for symptom control and prevention (**Figure 41-5** »). Teaching plans for older adults commonly center on nutrition, physical activity, personal safety, medications, and the need for follow-up healthcare appointments (Bastable, 2014).

Source: Javier Larrea/age fotostock/Alamy Stock Photo.

Figure 41-4 » When teaching adult patients, make sure to answer all their questions so that they understand the need for and benefit from the treatment.

When teaching older adults, nurses must address aging factors that influence comprehension and develop teaching plans that ensure maximal learning can take place. Sensory alterations (especially hearing, vision, and touch), energy level, physical abilities, cultural influences, memory, response time, and stress can all affect an older adult's ability to learn and/or retain information, and they may be significant factors in nonadherence with treatment regimens. Older adults also have past experiences, insight, and knowledge that affect their current attitudes toward healthcare teaching. The nurse should respect older patients and use these past experiences, knowledge, and skills to help them learn.

To maximize learning and establish trust, the nurse must include older adults when developing a teaching plan and setting goals. Moreover, to achieve outcomes specific to older adults, the nurse should allow adequate time for processing information, provide repetition, and include significant others or primary caregivers as necessary. Teaching handouts that are written at a fifth- to sixth-grade reading level and use large (e.g., at least 14-point font) black print on matte paper are practical and effective tools. As with all age groups, the nurse should use a calm approach; create a peaceful environment; allow time for questions and practice if teaching a skill or task; and provide feedback and encouragement. The nurse must also

Figure 41-5 » A home healthcare nurse demonstrates for an older patient how to properly dispose of unused medication.

evaluate the effectiveness of the teaching and learning, reinforce teaching as needed, and document the intervention (Osborn et al., 2013).

Teaching Patients with Special Needs

The term *special needs* encompasses not only patients with physical, cognitive, and/or developmental impairments, but also patients facing social and environmental issues that affect their health and well-being. When working with a special needs patient, the nurse should perform a complete assessment of the individual's home environment, support systems, and unique level of development prior to any teaching efforts. Later, during teaching, the nurse may need to stress the importance of interprofessional interventions from therapists or medical social workers to ensure that all of the patient's health and wellness needs are met.

Clinical Example D

Lily is an active 5-year-old girl who fell off a swing at the playground, fracturing her left clavicle for the second time in 18 months. The physician tells Lily's mother that CT scans reveal the need for minor surgical correction that will require a 2-day hospital stay. As the nurse prepares to teach both Lily and her mother about the upcoming procedure, Lily begins tearfully asking for her favorite doll "so my booboo can feel better." Lily's mother also verbalizes concern about what her daughter's postsurgical care may require. She is a single working mother with minimal support and another daughter—an 11-year-old who she thinks may be too young to stay home with her little sister. She further explains that she cannot afford to take much time off from work.

Critical Thinking Questions

1. What priority actions should the nurse take at this time?
2. Can learning take place? Why or why not?
3. What strategies could the nurse use to enhance Lily's learning and calm her fears?
4. Discuss strategies that the nurse could use to teach and provide reassurance to Lily's mother and address her concerns.

Technology, Health Information, and Patient Teaching

Technology has dramatically transformed many aspects of healthcare, including the ways in which patients and healthcare providers obtain and use health information.

Patients and Online Health Information

The internet in particular has changed the way that patients search for information about medical conditions and treatments on their own. In addition, technology-based tools offer nurses new and innovative methods for working with patients. These tools are part of the **e-health** movement, which focuses on making healthcare resources more accessible to patients by transferring them to electronic media (World Health Organization, 2013a).

The Pew Research Center reports that 87% of American adults use the internet and 72% seek health information online (Pew Research Center, 2014). Many published articles, clinical studies, and scholarly journal publications are available online and through health-related applications. Unfortunately, many websites contain unreliable, questionable, and biased information. Healthcare providers must review online sources carefully to identify those that are reliable. They must also teach patients how to discern trustworthy information from false or potentially dangerous health advice. The following points may be helpful for both nurses and patients who are searching for health information on the internet:

- Consider the author's credentials and whether or not the information is on a personal website or a site sponsored by an organization.
- Review any "About Us," "Philosophy," or "Background" links on the page.
- Look for citations or references documented with footnotes and working links to other sources of information.
- Check the publication or posting date on the page.

Authors with credentials from known and respected universities or organizations are preferable to authors with unknown or questionable credentials. However, information provided on a blog or personal website should be questioned, even if the author appears credible.

Organizational websites should be carefully vetted as well. In general, websites associated with reputable organizations such as the Mayo Clinic, the Cleveland Clinic, or the American Heart Association are reliable, whereas sites associated with private companies promoting medical products should be viewed cautiously. Reputable sites will often acknowledge that the information they provide is not a substitute for professional advice and will encourage individuals to follow up with their healthcare providers. In addition, .gov, and .edu domains are generally reliable sources of health information. The domain .org is generally reserved for nonprofit organizations. The information from nonprofit professional organizations, such as the American Academy of Allergy, Asthma, and Immunology, and nonprofit advocacy organizations, such as the Alzheimer's Association and the National Parkinson

Foundation, is usually helpful and reliable, but caution patients to vet information from sites that are less well known.

Citations and references should be reliable and of high quality. Journal articles, research studies, and documents from the National Institutes of Health (NIH) and the Centers for Disease Control and Prevention (CDC) are examples of quality references; popular nonscientific or “wiki” websites are not. References should be current unless they are classic or foundational studies in a particular field or area of medicine. In general, information published in the past 4 to 5 years can be considered current (HealthIT.gov, 2013). The publication or posting date on the page itself should also be current. (See the Stay Current feature for more about identifying current, reliable web-based health information.)

» Stay Current: The Health on the Net Code of Conduct (HONcode) was established by the Health on the Net Foundation to accredit health related websites for reliability (Health on the Net Foundation, 2016). It has become an important resource for validating ethical, internet-based information. Any health or medical website intended for patients, health professionals, or the general public can request a review in order to receive the HONcode certification of reliability. Once approved, the HONcode logo can be publicly displayed on the website to indicate its credibility. For further information see: Health on the Net Foundation, <http://www.hon.ch/HONcode/Patients/Visitor/visitor.html>

Incorporating Technology in Patient Teaching

In addition to helping patients become more informed consumers of web-based health information, nurses can use a variety of technologies when teaching patients. The type of technology used will depend on the particular health topic; the resources available; and patients’ comfort with, preferences about, and willingness to use technology.

One of the most basic—and simplest—forms of technology in patient teaching is directing patients to specific health-related websites. Before doing so, the nurse must

carefully vet websites to ensure that the information is reputable, accurate, and easy to understand. For example, a patient with chronic obstructive pulmonary disease (COPD) might benefit from information and resources available on the American Lung Association’s website.

In addition, some hospitals and clinics have e-health portals that enable nurses to print educational information personalized for each patient based on condition and age. These resources may be particularly useful for patients who are not tech-savvy or who prefer to keep printed information on hand. If patients show interest in accessing this information on their own and the portal is structured for patient access, the nurse can also provide information to the patient about logging on to the portal from a home computer.

Some facilities also have smart TVs that enable patients to watch videos and use health learning applications. Some of these applications may be downloadable to patients’ tablets or mobile phones, enabling patients to work through them at their own pace or revisit them at a later time. The applications may also include tutorials and quizzes that can help reinforce patient learning.

More individualized uses of technology may also be used in patient teaching. For example, webcams allow the nurse to video chat with patients at remote locations. This may be particularly useful when working with patients who are homebound. It can also be effective for observing patients performing self-care tasks in the home.

Use of e-health interventions may be especially helpful with the adolescent population, which is acclimated to obtaining and sharing information online. A review of five randomized controlled trials that examined the use of e-health with youth patients with depression or anxiety found that online cognitive-behavioral therapy (CBT) interventions may be helpful in reducing levels of acuity when offered with supervision in school and clinical settings (O’Dea, Calear, & Perry, 2015). E-health interventions for use with adolescents with other disorders, such as diabetes, are also being investigated.

REVIEW The Concept of Teaching and Learning

RELATE Link the Concepts

Linking the concept of teaching and learning with the concept of communication:

1. How does the quality of a nurse’s communication skills impact his or her ability to teach?
2. How does the ability to communicate with people who speak a different language impact the teaching process?

Linking the concept of teaching and learning with the concept of advocacy:

3. How does the role of the nurse as teacher combine with the role of the nurse as advocate?
4. A nurse teaches a patient newly diagnosed with diabetes how to provide self-care to reduce the risk of complications. How does teaching this patient serve the nurse’s advocacy role?

REFLECT Apply Your Knowledge

Samuel Jordan is a 33-year-old man who has worked as a nurse on the medical unit of a local acute care facility for the past 4 years. He has 9 years of nursing experience, having worked at another facility for 5 years before accepting this position. The unit is usually staffed with registered nurses (RNs), nursing assistants, and licensed practical nurses, along with a clinical secretary who transcribes orders, answers the phone, and obtains supplies. Throughout the course of an average day, Samuel interacts with many different members of the healthcare team.

1. What teaching opportunities is Samuel likely to encounter on a normal workday?
2. What teaching opportunities might Samuel encounter on his days off?
3. How does teaching impact Samuel’s self-evaluation of his work performance?

Exemplar 41.A

Patient/Consumer Education

Exemplar Learning Outcomes

41.A Analyze patient/consumer education as it relates to teaching and learning.

- Differentiate environments where nurses teach.
- Outline the steps of developing a teaching plan.
- Summarize the aspects of identifying learning needs.
- List special teaching strategies.

Overview

Providing patient education is a major aspect of nursing practice and an important independent nursing function. A variety of sources support this idea, beginning as early as 1992 with the American Hospital Association's passage of *A Patient's Bill of Rights*, which recognizes education as a right of all patients. The Joint Commission (TJC) followed suit in 1993 when it first established standards for patient education; TJC has continued to expand its standards over the years and emphasizes the importance of ensuring patient understanding of the material taught (Bastable, 2014). In 2010, the U.S. Department of Health and Human Services initiated *Healthy People 2020*, which promotes education that improves individuals' ability to make informed health choices. In addition, state nurse practice acts include teaching as a function of nursing and a legal and professional responsibility.

Although nurses play a key role in educating patients, patients are not passive recipients of information. In fact, many patients are taking an increasingly active role in all aspects of their health.

Exemplar Key Terms

Anticipatory guidance, 2684
 Anticipatory problem solving, 2685
 Health literacy, 2677
 Return demonstration, 2674
 Teach-back method, 2686

Good patient education efforts recognize the patient's role as consumer. Accordingly, education should help patients take a more active role in their health by providing them with information about methods for reducing health risk factors, increasing their level of wellness, and taking protective measures. **Box 41-4** lists specific areas of health teaching that address these areas.

This exemplar takes a closer look at the steps nurses can take to provide teaching that promotes patient health and empowers patients as consumers. It begins with a discussion of the different environments in which nurses may engage in teaching. It also discusses methods for developing specific, individualized patient teaching plans. In addition, it looks at methods for identifying patient learning needs and implementing teaching plans. Finally, the exemplar explores methods for evaluating teaching and learning.

Teaching Environments

Nurses teach patients in many different settings, including hospitals, primary care clinics, urgent care centers, their homes, and assisted living and long-term care facilities.

Box 41-4

Common Topics for Patient Education

Health Promotion

- Human growth and development
- Fertility control
- Hygiene
- Nutrition
- Exercise
- Stress management
- Lifestyle modification
- Resources within the community

Illness/Injury Prevention

- Health screening (e.g., blood glucose levels, blood pressure, blood cholesterol, Pap tests, mammograms, vision and hearing tests, routine physical examinations)
- Reducing health risk factors (e.g., lowering cholesterol levels)
- Specific protective health measures (e.g., immunizations, use of condoms, use of sunscreen, use of medication, umbilical cord care)
- First aid
- Safety (e.g., proper use of seat belts, helmets, walkers)

Health Restoration

- Information about tests, diagnoses, treatment, and medications
- Self-care skills or skills needed to care for a family member
- Resources within the healthcare setting and the community

Adaptation to Altered Health and Function

- Lifestyle adaptations
- Problem-solving skills
- Adaptation to changing health status
- Strategies to deal with current problems (e.g., home IV skills, medications, diet, activity limits, prostheses)
- Strategies to deal with future problems (e.g., fear of pain with terminal cancer, future surgeries, or treatments)
- Information about available treatments and likely outcomes
- Referrals to other healthcare facilities or services
- Facilitation of strong self-image
- Grief and bereavement counseling

TABLE 41-3 Comparison of the Teaching Process and the Nursing Process

Step	Teaching Process	Nursing Process
1	Collect data; analyze patient's learning strengths and deficits.	Collect data; analyze patient's strengths and deficits.
2	Make educational diagnoses.	Make nursing diagnoses.
3	Prepare teaching plan: <ul style="list-style-type: none"> ■ Write learning outcomes. ■ Select content and time frame. ■ Select teaching strategies. 	Plan nursing goals/desired outcomes and select appropriate interventions.
4	Implement teaching plan.	Implement nursing strategies.
5	Evaluate patient learning based on achievement of learning outcomes.	Evaluate patient outcomes based on achievement of goal criteria.

Nurses may also teach large and small groups of learners in community health education programs.

Teaching Individual Patients

When teaching individual patients and their families, the nurse is in a position to promote healthy lifestyles through the application of health knowledge, the change process, learning theories, and nursing and teaching processes. As with nursing interventions, patient education opportunities should be tailored to needs identified via consultation with patients and their families. In fact, the teaching process shares many similarities with the nursing process, including assessment of needs, planning, implementation, and evaluation. See **Table 41-3** for a more detailed comparison of the teaching and nursing processes.

Nurses may teach individual patients in one-to-one teaching episodes. For example, the nurse may teach about wound care while changing a patient's dressing or may teach about diet, exercise, and other lifestyle behaviors that minimize the risk of heart attack when caring for a patient who has a cardiac problem. The nurse may also be involved in teaching family members or other support people who are caring for a patient. For instance, nurses who work in obstetric and pediatric areas regularly teach parents (and sometimes grandparents) how to care for children.

Because of the current trend toward shorter hospital stays, nurses often face time constraints on patient education. Accordingly, nurses must take care to provide education that will ensure the patient's safe transition from one level of care to another, then make appropriate plans for follow-up education in the patient's home if necessary. Discharge plans must include information about what the patient has been taught before transfer or discharge, as well as what the patient still must learn to perform self-care in the home or other residence.

When educating patients, the nurse must ensure that the environment is conducive to learning. In addition, both the patient and the nurse must be adequately prepared for the teaching session. The following is a list of recommendations nurses should keep in mind when preparing the environment, the patient, and themselves for teaching:

- Provide a calm environment to decrease distractions.
- Take time in teaching. Observe the patient for signs or feelings of being overwhelmed, confused, and/or anxious.
- Adapt your teaching plan to reflect the patient's reactions. For example, if the patient seems confused, avoid

moving on to more information. Determine where the patient became confused and address the issue until understanding occurs before moving to new information.

- Remember that instructions may need to be repeated several times, depending on the patient's level of anxiety and stress.
- Evaluate the patient's (or support person's) ability to perform a skill through **return demonstration**. Having the patient (or support person) demonstrate how they would perform the skill in response to a "what if" situation allows that individual to exhibit mastery of the skill.

Teaching in the Community

Nurses are often involved in community health education programs. Such teaching activities may be voluntary as part of the nurse's involvement in an organization (e.g., the American Red Cross, Planned Parenthood), or they may be part of the nurse's job responsibilities. Nurses work in a variety of community settings, including local health departments, schools, and colleges and universities. Community teaching activities may be aimed at large groups of people who have an interest in some aspect of health; examples include nutrition classes, cardiopulmonary resuscitation (CPR) or cardiac risk factor reduction classes, and bicycle or swimming safety programs. Community education programs also can be designed for small groups or individual learners, as is often the case with childbirth classes or family planning classes.

Clinical Example E

When providing teaching to groups, it is essential to tailor the teaching to the members of each group. Consider the following example: During fall sports season, three athletes at a local high school develop staph infections. When deciding how to best provide education related to this situation, the school nurse identifies several groups who have a stake in the health and well-being of student athletes: (1) the athletes themselves, (2) their parents and immediate family members, (3) the coaches, and (4) the teachers and other staff at the school.

The nurse recognizes that providing each group with only a hand-out will be insufficient. Instead, she decides to work with the school's athletic director and physical trainer to develop a teaching session for the coaches that reinforces individual hygiene and also provides local and state regulations related to preventing staph infections. She further plans to demonstrate how to properly clean equipment such as wrestling mats.

In collaboration with the trainer, the nurse also develops and schedules a teaching session for the athletes themselves. Recognizing

the importance of peer influence in this group, the nurse obtains parental permission for one of the athletes who acquired a staph infection to come speak to the others about what it was like and to help her persuade the other students to take steps to avoid infection.

Critical Thinking Questions

1. What are the primary takeaways from the teaching sessions for each stakeholder group?
2. How would the teaching methods used in the session for the coaches differ from those used in the session for athletes?
3. Discuss strategies that the nurse could use to promote individual hygiene among student athletes.

Developing a Teaching Plan

Before creating a teaching plan, the nurse must assess the needs of the patient or group. For individual patients (and their families), the nurse should consider the patient's health history, physical and psychosocial assessment, and available support systems (e.g., caregivers or access to transportation). The nurse should also note various factors that influence the learning process, such as readiness and motivation to learn, reading and comprehension level, and mobility.

Using the Health History

Several elements of a patient's health history can provide clues about the patient's learning needs. These elements include age and developmental level; the patient's understanding and perceptions of the health problem; the patient's

health beliefs and practices; cultural factors; economic factors; the patient's learning style; and the patient's support systems. Some examples of interview questions that help elicit this information are provided in **Box 41-5** ».

Note that the same elements that affect an individual patient's learning needs also affect the needs of individuals in communities. For example, consider a nurse who is planning a teaching session on health promotion for individuals with high blood pressure. This session will be presented to residents at an independent living facility. Although the teaching plan for the group will be different from that for a single patient, the plan should still consider factors such as the residents' primary language, age and developmental level, and economic situation (e.g., access to transportation, health insurance coverage). The following sections take a closer look at these and other elements that influence patients' learning needs.

Age and Developmental Level

Age generally provides information about a patient's developmental status that may indicate the need for distinctive health teaching content and teaching approaches. Posing simple questions to school-age children and adolescents can elicit information on what they know. Observing young children at play also provides information about motor and intellectual development as well as relationships with other children. For older adults, conversation and questioning may reveal slow recall or limited psychomotor skills, sensory

Box 41-5

Interview Questions That Help Reveal Patient Learning Needs

Questions About the Primary Health Problem

- Tell me what you know about your current health problem. What do you think caused it?
- What concerns do you have about your health problem?
- How has the problem affected what you can or cannot do during your usual activities (e.g., work, recreation, shopping, and housework)?
- What do you or did you do at home to relieve the problem? How helpful was it?
- Have the treatments you have started helped your problem? If so, how?
- What, if any, difficulties have the treatments caused you (e.g., inconvenience, cost, discomfort)?
- Tell me about the tests (surgery, treatments) you are going to have.

Questions About Health Beliefs

- How would you describe your health generally?
- What things do you usually do to keep healthy?
- What health problems do you think you may be at risk for because of family history, age, diet, occupation, inadequate exercise, or other habits, such as smoking?
- What changes would you be willing to make to decrease your risk for these problems or to improve your health?

Questions About Cultural Factors

- What language do you use most often when speaking and writing?
- Are you seeking the advice of another health practitioner?

- Do you use herbs or other medications or treatments commonly used by members of your cultural group? If so, does your current primary care provider know about these?
- Has your primary care provider given you any advice or treatments that conflict with values or beliefs you consider important?
- When a conflict arose, what did you do?

Questions About Learning Style

- Note the patient's age and developmental level.
- What level of education have you achieved?
- Do you like to read?
- Where do you usually obtain health information (e.g., primary care provider, nurse, magazines, books, internet, or pharmacist)?
- How do you best learn new things?
 - By reading about them?
 - By talking about them?
 - By watching a movie or demonstration?
 - By using a computer?
 - By listening to a teacher?
 - By first being shown how something works, then doing it yourself?
 - On your own or in a group?

Questions About Support Systems

- Would you like a family member or friend to help you learn about the things you must do to take care of yourself?
- Who do you think would be interested in learning with you?

deficits, and learning difficulties. (See the section on Lifespan Considerations for additional information.)

Understanding of the Health Problem

Patients' perceptions of their current health problems and concerns may indicate deficient knowledge or misinformation. In addition, discussion of the problem's effects on the patient's usual activities can alert the nurse to other areas that require instruction. For example, individuals who cannot manage self-care at home often need information about community resources and services.

Health information can be difficult to obtain prior to providing teaching in a group setting. Whenever possible, the nurse should try to assess participants' health perceptions in advance. Some strategies for doing so include the following:

- Circulating brief surveys
- Surveying staff at the setting where teaching will be provided
- Conducting brief surveys as patients arrive for the teaching session

For instance, in the staph example mentioned earlier, the school nurse might ask the coaches to circulate surveys to athletes at the beginning of practice a week before the session. An alternative might be to hold a brief question-and-answer session with team captains to get a sense of athletes' general habits, practices, and attitudes toward hygiene.

Health Beliefs and Practices

A patient's health beliefs and practices are important to consider in any teaching plan. The health belief model described in the module on Health, Wellness, and Illness provides a predictor of preventive health behavior. However, even if a nurse is convinced that a particular patient's health beliefs should be changed, doing so may not be possible because so many factors are involved in patient health beliefs.

Cultural Factors

Many cultural groups have their own beliefs and practices, some of which are related to diet, health, illness, and lifestyle. The cultural practices and values held by patients will affect their learning needs. For example, a patient may understand the healthcare information being taught, but she may not use any of this information if she believes in following the practices of her culture of origin.

Economic Factors

Economic factors can also affect learning. For example, a patient who cannot afford to obtain a new sterile syringe for each insulin injection may find it difficult to learn to administer insulin when the nurse teaches that a new syringe should be used every time. In a group setting, nurses may be teaching individuals who have limited access to transportation, who lack health insurance, or who are dependent on others for their financial security. Nurses must take these factors into account when planning education sessions in the community.

Learning Styles

Considerable research exists with regard to learning styles. In general, this research indicates that the best way to learn

varies with the individual. Some individuals are visual learners and learn best by watching. Others do not visualize an activity well but learn best by actually manipulating equipment and discovering how it works. Many individuals learn best from reading information presented in an orderly fashion. Still others learn best in groups where they can relate to other people. For some, stressing the thinking part of a skill and its logic will promote learning. For other people, stressing the feeling part or interpersonal aspect motivates and promotes learning.

The nurse seldom has the time or skills to assess each learner, identify his or her particular learning style, then adapt teaching accordingly. What the nurse can do, however, is ask patients how they have learned information best in the past or how they like to learn. Many people know what helps them learn, and the nurse can use this information to plan the teaching. Using a variety of teaching techniques and varying activities during teaching are good ways to match learners with learning styles. One technique will be most effective for some patients, whereas other techniques will be suited to patients with different learning styles.

It is particularly important to use a variety of teaching techniques when providing education in community settings. The nurse can combine videos, whiteboards, and opportunities to practice demonstrations to ensure the highest rate of retention among group members. PowerPoint presentations can also be helpful. Some learners may benefit from receiving a copy of the plan or agenda of the session in advance so they can follow along with the presentation.

Support Systems

When compiling the health history, the nurse must explore the patient's support systems to determine the extent to which other people may enhance learning and offer support. In many cases, family members or close friends can help patients perform required skills at home and maintain necessary lifestyle changes.

Using the Physical Examination

When working with individual patients, the general survey part of the physical examination provides useful clues to the patient's learning needs, including those related to mental status, energy level, and nutritional status. Other parts of the physical examination reveal data about the patient's physical capacity to learn and to perform self-care activities. For example, visual ability, hearing ability, and muscle coordination affect the selection of content and approaches to teaching.

Determining Readiness to Learn

Patients who are ready to learn often behave differently from those who are not. A patient who is ready may search out information, for example, by asking questions, reading books or articles, talking to others, and generally showing interest. The individual who is not ready to learn is more likely to avoid the subject or situation. In addition, the unready patient may change the subject when it is brought up by the nurse. For example, if the nurse says, "I was wondering about a good time to show you how to change your dressing," a patient who is not ready to learn might respond "Oh, my wife will take care of everything." Using cues from

the patient can result in teaching moments (small chunks of time in which the patient is receptive to information). Always observe the patient's reaction during a teaching moment because it may lead into a longer period of receptiveness.

When assessing a patient's readiness to learn, the nurse should consider the following characteristics:

- **Physical readiness.** Is the patient able to focus on things other than physical status, or are pain, fatigue, and immobility consuming all of the patient's time and energy?
- **Emotional readiness.** Is the patient emotionally ready to learn self-care activities? Patients who are extremely anxious, depressed, or grieving over their health status are not ready.
- **Cognitive readiness.** Can the patient think clearly at this point? Are the effects of anesthesia and analgesia altering the patient's level of consciousness?

Nurses can promote readiness to learn by providing physical and emotional support during the critical stage of recovery. As the patient stabilizes physically and emotionally, the nurse can then provide actual opportunities to learn.

In group settings, when attendance is voluntary, patients are more likely to be ready to learn new information. When attendance is compulsory, such as in a school setting or an inpatient treatment facility, patient readiness to learn may vary considerably. In these instances, it is especially important that nurses be able to manage problem behaviors, such as monopolizing. (See the module on Communication for more information.)

Assessing Motivation

Motivation relates to whether the patient wants to learn, and it is usually greatest when the patient is ready, the learning need is recognized, and the information being offered is meaningful to the patient. Assessment of motivation, however, may be difficult. Nurses should be alert for information that indicates a readiness for change, such as a patient saying, "I'm really ready to lose weight this time." On the other hand, nonverbal behaviors such as lack of interest, wandering attention, and missed appointments can indicate decreased motivation to learn.

Nurses can use the following strategies, as appropriate, to increase patient motivation in both individual and group settings:

- Relate the learning to something the patient values and help the patient see the relevance of the learning.
- Help the patient make the learning situation pleasant and nonthreatening.
- Encourage self-direction and independence.
- Demonstrate a positive attitude about the patient's ability to learn.
- Offer continuing support and encouragement as the patient attempts to learn (i.e., positive reinforcement).
- Create a learning situation in which the patient is likely to succeed. (Succeeding in small tasks motivates the patient to continue learning.)
- Assist the patient in identifying the benefits of changing behavior.

Box 41-6

Populations Most Likely to Experience Limited Health Literacy

- Adults older than 65 years of age
- Recent refugees and immigrants
- Individuals with less than a high school degree or GED
- Individuals with incomes at or below the poverty level
- Nonnative speakers of English (USDHHS, n.d.)

Assessing Health Literacy

Literacy and *health literacy* are two closely related ideas. Literacy is a comprehensive measurement of an individual's mathematical, reading, writing, and language skills. A patient's literacy level affects her ability to understand and use information. **Health literacy** refers to the individual's ability to use literacy skills as a means of obtaining, understanding, and applying health information (CDC, 2015). Essentially, health literacy allows the patient to make sense of health information and use that information to make sound decisions about healthcare. The nurse must assess a patient's health literacy to create an effective teaching plan.

Health literacy is important because it impacts patient outcomes. Typically, patients with higher levels of health literacy have better outcomes. For example, patients with higher health literacy are more likely to read a prescription label accurately and take the correct number of pills at the correct times of day. Patients with low health literacy, on the other hand, are more likely to experience adverse events and hospitalization. Research suggests that more than 50% of North Americans do not possess the skills needed to learn about and manage their health adequately (Hadden, 2015; Manafo & Wong, 2012). **Box 41-6** » lists the groups at the greatest risk of low health literacy. The Focus on Diversity and Culture feature goes into further detail about health literacy in immigrant populations.

The large percentage of people with low health literacy is particularly worrisome in light of the increased availability of health information online. In order to address this concern, U.S. government health agencies have developed programs and initiatives designed to educate individuals and promote national and global health. In 2010, the U.S. Department of Health and Human Services (USDHHS) released the *National Action Plan to Improve Health Literacy*. This plan is intended to help meet the goals and objectives outlined by *Healthy People 2020* (USDHHS, 2010). The CDC also developed a website for individuals, organizations, and health-care providers that aims to improve health literacy and public health (CDC, 2016). This site is simply titled *Health Literacy* and can be accessed at <http://www.cdc.gov/healthliteracy/>.

Clinical Example F

David Rodriguez is a 28-year-old man who had an emergency appendectomy yesterday. He is to be discharged home later today. During discharge teaching, the nurse provides Mr. Rodriguez with handouts relating to wound care, medications, activity restrictions, and follow-up appointments. The nurse knows the handouts

will fit Mr. Rodriguez's learning style because he said he likes to read; in fact, the nurse observed Mr. Rodriguez reading a couple of times this morning.

Critical Thinking Questions

1. Should the nurse have used the handouts as a learning tool? Why or why not?
2. What strategies might patients use to avoid embarrassment by having to admit they cannot read English?
3. What strategies might a nurse use to help a patient who cannot read English learn about self-care?

Nurses play a major role in improving health literacy. An important first step for nurses is assessing a patient's general literacy. (See the Patient Teaching feature for information about patient behaviors that suggest a literacy problem.) Once a patient's literacy level has been determined, the nurse should adjust written materials to the patient's level. In general, educational materials should be written at a fifth- or sixth-grade reading level. Materials should use the active voice rather than the passive voice and be written in second person (*you*) rather than third person (*the patient*). Priority information should appear first and be repeated several times. Sentences should be short and use easy, common one- or two-syllable words. For example, the word *use* should take the place of *utilize*, and the word *give* should be used rather than *administer*. Larger type size (14- to 16-point font)

Focus on Diversity and Culture

Health Literacy in Immigrant Populations

Immigrants tend to have lower health literacy than non-immigrants. Low health literacy is more responsible for a perceived lower quality of care in immigrants than many other factors, including education, income, and health insurance coverage (Calvo, 2016). Public initiatives intended to improve health literacy do not always reach immigrants. This may be the result of economic status, language and other social barriers, or both. In addition, the combination of low health literacy and limited English proficiency cause immigrants to be at high risk for poor health (Sentell & Braun, 2012). For the same reasons, health promotion and disease prevention services are often underused by immigrant populations as well (World Health Organization, 2013b).

Interventions that have been found effective for improving health literacy and access to services in immigrant populations include the use of informational pictograms and signs translated into multiple languages. Translated signs in particular are useful not only for helping patients learn, but also for creating feelings of inclusion and belonging at the facility where they are used.

The use of cultural mediators may also be successful in improving health literacy and quality of care for immigrant patients. Cultural mediators are individuals with an understanding of patients' native cultures and that culture's view of health, wellness, and medical interventions (World Health Organization, 2013b). The cultural mediator may also be versed in the migrant experience and may speak the patients' native language.

A key to improving immigrants' health literacy and access to healthcare initiatives is engaging these groups in the planning and implementation of strategies. The effectiveness of these strategies should regularly be evaluated by immigrant patients, cultural mediators, and healthcare providers.

should be used, and important words should be boldfaced for emphasis. Simple pictures, drawings, or cartoons should also be used if appropriate.

SAFETY ALERT Individuals with low reading skills may struggle not only with health teaching but with giving accurate informed consent for treatment. When working with these patients, review all components of the procedure and the consent document carefully, allowing time for the patient to ask questions.

Individuals with good reading skills are unlikely to be offended by simple reading material; in fact, they may prefer easy-to-read information. However, even the simplest written directions will not be helpful to a patient with low or no reading skills. When working with these patients, the nurse should use multiple teaching methods, including pictures, role playing, and hands-on practice. The nurse can also read important information to the patient, taking care to emphasize key points in simple terms. It may also be helpful to associate new information with information the patient already knows or associates with his job or lifestyle.

Regardless of a patient's health literacy level, it is generally a good idea for the nurse to limit the amount of information presented in a single teaching session. Instead of one long session that provides a great deal of information, it is often better to provide more frequent sessions that focus on one or two major points. All teaching should involve the patient and use repetition to reinforce the information presented. Finally, the nurse should obtain feedback during the session by asking the patient specific questions about the information presented or asking the patient to repeat what was learned in her own words.

SAFETY ALERT Highly technical language and nursing jargon are confusing to patients—even those with higher levels of health literacy. Confusing instructions may be ignored, placing the patient's health at risk. Verbal and written teaching must use simple, clear language that is readily understood by laypersons.

Patient Teaching

Identifying Low Literacy Behaviors in Patients

Patients often will not admit to having difficulty reading because of the embarrassment it brings them, and many people at the lowest reading levels report that they "read well." A nurse who suspects a patient has difficulty reading may ask the patient tactful questions, such as "Would you like me to go over it with you?"

It can be difficult to assess a patient's health literacy skills because the shame and stigma associated with limited literacy are major barriers. The following patient behaviors may cause a nurse to suspect a literacy problem:

- A pattern of nonadherence
- Insistence that they already know the information
- Reliance on friends or family members to read the document aloud
- A pattern of excuses for not reading the instructions (e.g., claiming that glasses are broken)

Identifying Learning Needs

Nursing diagnoses for patients with learning needs can be designated in two ways: as the patient's primary concern or problem, or as the etiology of a nursing diagnosis associated with the patient's response to health alterations or dysfunction.

Learning Need as the Diagnostic Label

NANDA International (NANDA-I) is charged with providing evidence-based diagnosis terminology and guidance to the nursing community to assist in providing consistent, evidence-based care across all settings in which nurses care for patients. NANDA-I's diagnostic labels list includes *Deficient Knowledge*, which is an appropriate diagnosis whenever a patient's learning need is the primary concern because the patient lacks knowledge related to a specific healthcare issue or topic (NANDA-I © 2014).

Whenever the nursing diagnosis label *Deficient Knowledge* is used, either the patient is seeking health information or the nurse has identified a learning need. The area of deficiency should always be included in the diagnosis. The following examples both use the NANDA-I label *Deficient Knowledge* as the primary concern:

- *Deficient Knowledge* of low-calorie diet related to inexperience with newly ordered therapy.
 - *Deficient Knowledge* of home safety hazards related to denial of declining health and living alone.
- (NANDA-I © 2014)

When working with patients who have a knowledge deficit, the nurse should provide information that has the potential to change the patient's behavior rather than focus on the behaviors caused by the patient's lack of knowledge.

A second nursing diagnosis label that may apply when a learning need is the primary concern is *Readiness for Enhanced Knowledge*. When this diagnostic label is used, the patient is seeking information. Note that the patient may or may not have an altered response or dysfunction at the time of the diagnosis; he or she may simply be seeking information to improve health or prevent illness. This diagnosis is especially appropriate for patients attending community health education programs. The following example uses the NANDA-I label *Readiness for Enhanced Knowledge* as the primary concern:

- *Readiness for Enhanced Knowledge* related to desire to improve health behaviors and decrease risk of heart disease.

This diagnosis may be appropriate for the patient who has identified a personal health risk for a cardiac condition and wants to minimize that risk through exercise.

Noncompliance is a third nursing diagnosis label that may be appropriate when a learning need is the primary concern. This label recognizes that the individual or caregiver may not always be able to follow the treatment or care plan as agreed (NANDA-I © 2014). The *Noncompliance* diagnostic label generally is used when patients have intent to comply but barriers affect their compliance. Factors that influence a patient's compliance with health teaching

include understanding or comprehension of the teaching, any negative side effects of the treatment, financial inability to carry out the treatment plan, language barriers, or poor teaching on the part of the healthcare team. *Noncompliance* should *not* be used for patients who are unable to follow instructions (e.g., because of cognitive disability) or for patients who make an informed decision to refuse or not follow the medical treatment (Wilkinson, 2013).

Deficient Knowledge as the Etiology

Another way to deal with patients' identified learning needs is to include deficient knowledge as the etiology, or second part, of the diagnosis statement.

Examples include the following:

- *Risk for Impaired Parenting* related to deficient knowledge of skills required for infant care and feeding.
- *Risk for Infection* related to deficient knowledge of sexually transmitted infections and their prevention.
- *Anxiety* related to deficient knowledge of bone marrow aspiration.

(NANDA-I © 2014)

Other nursing diagnoses in which a knowledge deficit can be the etiology include the following:

- *Injury, Risk for*
- *Breastfeeding, Ineffective*
- *Coping, Ineffective*
- *Health Maintenance, Ineffective*.

(NANDA-I © 2014)

Note also that most nursing diagnoses approved by NANDA-I imply a teaching-learning need. For example, the nursing diagnosis *Constipation* suggests the need for a review of bowel hygiene practices, including diet, hydration, and exercise/activity.

Establishing the Teaching Plan

When developing a teaching plan, the nurse should follow a series of steps, each of which is described in the following sections. Involving the patient in each step promotes the formation of a meaningful plan and stimulates patient motivation. In fact, patients who help develop the teaching plan are more likely to achieve the desired outcomes.

Determining Teaching Priorities

The first step in creating a teaching plan is to rank the patient's learning needs according to priority. The patient and the nurse should do this together, with the patient's priorities always being considered. Once a patient's priorities have been addressed, the patient is generally more motivated to concentrate on other identified learning needs. For example, a man who wants to know all about coronary artery disease may not be ready to learn how to change his lifestyle until he meets his own need to learn more about the disease. Nurses can also use theoretical frameworks, such as Maslow's hierarchy of needs, to establish priorities.

Setting Learning Outcomes

Once a patient's learning needs have been prioritized, the patient and nurse should work together to determine the desired learning outcomes. Learning outcomes are essentially the same as desired outcomes for other nursing diagnoses. In fact, they are written in the same way. Like patient outcomes, good learning outcomes:

- **State the patient (learner) behavior or performance, not the nurse behavior.** For example, an appropriate learning outcome would be "Identify personal risk factors for heart disease" (patient behavior), *not* "Teach the patient about cardiac risk factors" (nurse behavior).
- **Reflect an observable, measurable activity.** Performance of this activity may be visible (e.g., walking) or invisible (e.g., adding a column of figures). However, the nurse must be able to evaluate whether an unobservable activity has been mastered from some performance that represents the activity. For example, the performance of an outcome might be written as "Selects low-fat foods from a menu" (observable), *not* as "Understands low-fat diet" (unobservable). Examples of measurable verbs that can be used in learning outcomes are shown in **Box 41-7** ». Avoid using words such as *knows*, *understands*, *believes*, and *appreciates* because they are neither observable nor measurable.
- **May add conditions or modifiers as required to clarify what, where, when, or how the behavior will be performed.** Examples include "Demonstrates four-point crutch gait *correctly*" (condition), "Administers own insulin *independently* (condition) as taught," or "States *three* (condition) factors that affect blood sugar level."
- **Include criteria specifying the time by which learning should have occurred.** For example, "The patient will state three things that affect blood sugar level *by the end of the second diabetes class*."

Box 41-7

Examples of Verbs for Writing Learning Outcomes

Cognitive Domain	Affective Domain	Psychomotor Domain
Compares	Accepts	Assembles
Describes	Attends	Calculates
Evaluates	Chooses	Changes
Explains	Discusses	Demonstrates
Identifies	Displays	Measures
Labels	Initiates	Moves
Lists	Joins	Organizes
Names	Participates	Shows
Plans	Shares	Performs
Selects	Uses	
States		
Writes		

Learning outcomes can reflect the learner's command of simple to complex concepts. For example, the learning outcome "The patient will list cardiac risk factors" is a low-level knowledge outcome that simply requires the learner to identify all cardiac risk factors; it does not suggest application of the knowledge to the learner's own behaviors. In comparison, the learning outcome "The patient will list personal cardiac risk factors" requires that the learner not only know cardiac risk factors in general, but also know his own behaviors that place him at risk for cardiac disease.

When writing learning outcomes, the nurse must be specific about what behaviors and knowledge (cognitive, psychomotor, and affective) learners must have to positively influence their health state. In most cases, a patient's learning needs are more complex than simple acquisition of knowledge and include the application of that knowledge to oneself.

Choosing Content

The content of a teaching plan—or what is to be taught—is determined by the identified learning outcomes. For example, the learning outcome "Identify appropriate sites for insulin injection" requires that the teaching plan include content about the body sites suitable for insulin injections.

When choosing content, nurses can select among many sources of information, including books, nursing journals, the internet, and other nurses and primary care providers. Whatever sources the nurse chooses, the content should be:

- Accurate
- Current
- Based on learning outcomes
- Adjusted for the learner's age, culture, and ability
- Consistent with information the nurse is teaching
- Selected with consideration of how much time and what resources are available for teaching

Selecting Teaching Strategies

The method of teaching that the nurse chooses should be suited to the individual and to the material to be learned. For example, a patient who cannot read needs material presented in other ways; discussion is usually not the best strategy for teaching a patient how to give an injection; and a nurse who uses group discussion for teaching should be a competent group leader. As stated earlier, some people are visually oriented and learn best through seeing; others learn best through hearing and having a skill explained to them. **Table 41-4** » lists some teaching strategies the nurse may find useful.

Organizing Learning Experiences

To save nurses time in constructing their own teaching guides, some health agencies have developed guides for teaching sessions that nurses commonly give. These guides standardize content and teaching methods and make it easier for the nurse to plan and implement patient teaching. Standardized teaching plans also ensure consistency of

TABLE 41–4 Selected Teaching Strategies

Strategy	Major Type of Learning	Characteristics
Explanation or description (e.g., lecture)	Cognitive	Teacher controls content and pace. Learner is passive and therefore retains less information than when actively participating. Feedback is determined by teacher. May be given to individual or group.
One-to-one discussion	Affective, cognitive	Encourages participation by learner. Permits reinforcement and repetition at learner's level. Permits introduction of sensitive subjects.
Answering questions	Cognitive	Teacher controls most of content and pace. Learner may need to overcome cultural perception that asking questions is impolite and may embarrass the teacher. Can be used with individuals and groups. Teacher sometimes needs to confirm whether question has been answered by asking learner, for example, "Does that answer your question?"
Demonstration	Psychomotor	Often used with explanation. Can be used with individuals and small or large groups. Does not permit use of equipment by learner; learner is passive.
Discovery	Cognitive, affective	Teacher guides problem-solving situation. Learner is active participant; therefore, retention of information is high.
Group discussions	Affective, cognitive	Learner can obtain assistance from supportive group. Group members learn from one another. Teacher needs to keep the discussion focused and prevent monopolization by one or two learners.
Practice	Psychomotor	Allows repetition and immediate feedback. Permits hands-on experience.
Printed and audiovisual materials	Cognitive	Includes use of books, pamphlets, films, programmed instruction, and computer learning. Learners can proceed at their own speed. Nurse can act as resource person and need not be present during learning. Potentially ineffective if materials are written at too high a reading level. If English is the patient's second language, nurse should select materials that use the patient's preferred language (e.g., Spanish).
Role playing	Affective, cognitive	Permits expression of attitudes, values, and emotions. Can assist in development of communication skills. Involves active participation by learner. Teacher must create supportive, safe environment for learners to minimize anxiety.
Modeling	Affective, psychomotor	Nurse sets example by attitude, psychomotor skill.
Computer-assisted learning programs	All types of learning	Learner is active. Learner controls pace. Provides immediate reinforcement and review. Can be used with individuals or groups.

content for the learner, thereby decreasing the risk of confusion if different practices are taught. For example, when teaching infant bathing, the nurse on the unit should be consistent about which soaps are appropriate for the infant's bath and distinguish those that are not.

Whether the nurse is implementing a plan devised by another person or developing an individualized teaching

plan, the following guidelines can help the nurse sequence the learning experience:

- Start with something the learner is concerned about; for example, before learning how to administer insulin to himself, an adolescent patient may want to know how to adjust his lifestyle and yet still play football.

Evidence-Based Practice

Finding Teaching Strategies That Help Patients Understand, Apply, and Retain Information

Problem

Patient teaching is a professional obligation of nurses, but determining the most effective teaching strategy or strategies for each patient is challenging. The selected strategy must be appropriate for the patient's health literacy level and readiness to learn. It should help patients understand, apply, and retain the necessary information. With the many teaching methods available to nurses, identifying the ideal strategy for these outcomes can be difficult.

Evidence

A number of studies have been conducted to assess the effectiveness of various teaching methods on different patient populations. Ackerman et al. (2017) looked at patients' perceptions of understanding associated with various teaching methods. They looked specifically at information delivered to osteoarthritis patients age 55 and under via group-based programs, online resources, telephone helplines, mailed information, social media, and mobile applications. Patients rated understanding and accessibility of these methods on a scale from 1.0 (ineffective/inaccessible) to 10.0 (highly effective/highly accessible). Social media was rated as the least effective and least accessible method (with scores of 2.0 in each category). Mailed information and online programs were rated the most effective and most accessible (with effectiveness scores of 8.0 and 7.0 respectively for effectiveness and 10.0 and 9.0 respectively for accessibility).

Park et al. (2016) compared the application of information by patients exposed to two different teaching methods. Their research focused on patients' at-home bowel preparation for colonoscopy as assessed by the providers conducting the scope. Participants were divided into two groups: one group received traditional instruction about bowel preparation from a care provider while the other received instruction via video. Providers reported that 78.5% of traditional teaching patients exhibited good bowel preparation compared to 91.6% of video patients. As a result, colonoscopies for patients in the video group were of shorter duration than those of the traditional group; however, polyp detection among the two groups was not significantly different (19.0% in the traditional group and 19.2% in the video group).

White et al. (2013) addressed retention of information by patients exposed to the teach-back method for teaching self-care. (The teach-back method is explained in greater depth later in this exemplar.) The researchers examined the impact of this method on exacerbations and readmissions of patients with heart failure. Although the researchers did not find a strong relationship between the use of the teach-back model and readmission rates, the model was found to be effective in patient education: most patients were able to recall 75% of the information during their hospitalization (84.4%) and at 7 days after discharge (77.1%).

Implications

Although each of these studies assesses different components of effectiveness, they all suggest teaching methods involving visual media improve patient understanding, application, and retention of material. The types of visual media available to nurses vary widely, and the type selected by the nurse will be based on patient health literacy levels and readiness to learn. Visual media may be used alone or in combination with verbal teaching. One type of visual media may also be used to reinforce information taught via another type of visual media—for example, providing a patient with a written set of instructions after a teach-back session.

Critical Thinking Application

1. Discuss the ways in which visual media might be used differently to teach pediatric patients and adolescents about leukemia.
2. How do patient goals dictate the way in which visual media are used for patient teaching? Consider two diabetic patients, one who is learning to administer insulin and one who is struggling to stay active and lose weight. Assume both patients have similar health literacy and readiness to learn.
3. Is visual media appropriate for a patient who is visually impaired? In what ways could visual media be adapted for teaching this patient?

- Discover what the learner knows, then proceed to the unknown. This gives the learner confidence. Sometimes you will not know the patient's knowledge or skill base and will need to elicit this information either by asking questions or by having the patient fill out a form in advance of the session.
- Address early any area that is causing the patient anxiety. A high level of anxiety can impair concentration in other areas. For example, a woman who is highly anxious about her fear of needles breaking off in her skin may not be able to learn how to self-administer insulin injections until her fear is resolved.
- Teach the basics before proceeding to the variations or adjustments (i.e., proceed from simple to complex). It is confusing to learners to have to consider possible adjustments and variations before they master the basic con-

cepts. For example, when teaching a female patient how to insert a retention catheter, it is best to teach the basic procedure before teaching any adjustments that might be needed if the catheter stops draining after insertion.

- Schedule time for review of content and questions the patient may have to clarify information.
- If the patient does not have any questions, you can help introduce questions by saying, "A few frequently asked questions are. . ."

Showing Flexibility

The nurse needs to be flexible in implementing any teaching plan because the plan may need to be revised. For example, the patient may tire sooner than anticipated or be faced with too much information too quickly, the patient's needs may

change, or external factors may intervene. For instance, say the nurse and the patient plan to change the patient's dressing at 10 a.m., but when the time comes, the patient wants to observe the nurse once more before actually doing it himself. In this case, the nurse alters the teaching plan and discusses any desired information, provides another demonstration, and defers teaching the psychomotor skill until the next day.

It is also important for nurses to use teaching techniques that enhance learning and reduce or eliminate any barriers to learning, such as pain or fatigue. Many nurses find that they teach while performing nursing care (e.g., giving medication). Remember to document this informal teaching also.

Implementing the Teaching Plan

Knowledge alone is not enough to motivate individuals to change their behaviors. Rather, evidence indicates that patients are more likely to adopt new behaviors and follow their treatment plan when they are actively engaged in their care (Blazek et al., 2016). The Institute of Medicine's (IOM) 2012 report *Best Care at Lower Cost* also recommends that patients be "fully engaged participants at all levels" of their care.

Thus, when implementing a teaching plan, the nurse must actively seek ways to get the patient interested and involved in not just the teaching process, but the entire care process. This requires that the nurse reflect on the changes required as part of the care plan, the stages of the change process, the patient's willingness and perceived need to change, and any barriers to the change process. When the patient is ready to change his or her health behavior, the nurse can begin implementing the teaching plan. In doing so, the nurse may find it useful to keep the following guidelines in mind:

- Rapport between teacher and learner is essential. A relationship that is both accepting and constructive will best assist learning. The nurse should know the learner and the previously described factors that affect learning before planning and delivering the teaching.
- The teacher who uses the patient's previous learning in the present situation encourages the patient and facilitates learning new skills. For instance, an individual who already knows how to cook can use this knowledge when learning to prepare food for a special diet.
- The optimal time for each session depends largely on the learner. Whenever possible, ask the patient for help to choose the best time (e.g., when the patient feels most rested or when no other activities are scheduled). Be alert for patient cues that indicate a readiness to learn. For example, if a patient asks you why he needs a certain medication, the question provides an opportunity to explain the reason for the medication, signs to watch for, and whether follow-up laboratory work is needed.
- The nurse teacher must be able to communicate clearly and concisely. The words used in the teaching session need to have the same meaning to the patient as to the teacher. For instance, a patient who is taught not to put water on an area of skin may think a wet washcloth is permissible for washing the area. In effect, the nurse needs to explain that no water or moisture should touch the area.
- Using a layperson's vocabulary enhances communication. Often nurses use terms and abbreviations that have meaning to other health professionals but make little sense to patients. Even words such as *urine* or *feces* may be unfamiliar to some patients, and abbreviations such as ICU (intensive care unit) or PACU (postanesthesia care unit) are often misunderstood.
- The pace of each teaching session affects patient learning. Nurses should be sensitive to any signs that the pace is too fast or too slow. A patient who appears confused or does not comprehend material when questioned may be finding the pace too fast. When the patient appears bored and loses interest, the pace may be too slow, the learning period may be too long, or the patient may be tired.
- The environment can detract from or assist learning. For example, noise or interruptions usually interfere with concentration, whereas a comfortable environment promotes learning. If possible, the patient should be out of bed for learning activities. Most people associate their bed with rest and sleep, not with learning. Placing the patient in a position and location associated with activity or learning may influence the amount of learning that takes place. For instance, a patient who is shown a video while in bed may be more likely to become drowsy during instruction than a patient who is sitting in a bedside chair.
- Teaching aids can foster learning and help focus a learner's attention. To ensure the transfer of learning, the nurse should use the type of supplies or equipment the patient will eventually use. Before the teaching session, the nurse needs to assemble all equipment and visual aids and ensure that all audiovisual equipment is functioning effectively.
- Teaching that involves a number of the learner's senses often enhances learning. For instance, when teaching about changing a surgical dressing, the nurse can tell the patient about the procedure (hearing), show how to change the dressing (sight), and show how to manipulate the equipment (touch).
- Learning is more effective when the learners discover the content for themselves. Ways to increase learning include stimulating motivation and self-direction by, for example, providing specific, realistic, achievable outcomes; giving feedback; and helping the learner derive satisfaction from learning. The nurse may also enhance self-directed independent learning by encouraging the patient to explore sources of information. If certain activities do not assist the learner in attaining identified outcomes, these activities need to be reassessed; perhaps other activities can replace them. For instance, explanation alone may not be able to teach a patient to handle a syringe; actually handling the syringe may be more effective.
- Repetition reinforces learning. Summarizing content, rephrasing (using other words), and approaching the material from another point of view are ways of repeating and clarifying content. For instance, after discussing the kinds of foods that can be included in a diet, the nurse can describe the foods again, but in the context of the three meals eaten during one day.

- It is helpful to employ “organizers” to introduce the material to be learned. Advanced organizers provide a means of connecting unknown material to known material and generating logical relationships. For example, the following statement could be an advanced organizer: “You understand how urine flows down a catheter from the bladder. Now I will show you how to inject fluid so that it flows up the catheter into the bladder.” The details that follow are then seen within a framework that adds meaning.
- The anticipated behavioral changes that indicate learning has taken place must always be within the context of the patient’s lifestyle and resources. For example, it would be unreasonable to expect a woman to soak in a tub of hot water two times a day if she did not have a bathtub or had to heat water on a stove.

Special Teaching Strategies

One-to-one discussion is the most common method of teaching used by nurses. However, nurses can choose from a number of special teaching strategies, including anticipatory guidance, patient contracting, group teaching, technology-assisted instruction, discovery/problem solving, behavior modification, the teach-back method, and transcultural teaching. Any strategy the nurse selects must be appropriate for the learner and the learning objectives.

Anticipatory Guidance

Anticipatory guidance has been primarily associated with health promotion activities in pediatrics. In this context, nurses use anticipatory guidance to provide parents with information about developmental changes they can expect their child or children to exhibit as they grow and develop. However, anticipatory guidance can be used any time during the lifespan with the same focus: health promotion. For example, the nurse may provide anticipatory guidance to a family whose mother has Alzheimer disease to help them recognize safety concerns as the disease progresses. Anticipatory guidance may be provided to both individuals and groups. Nurses should consider several factors before providing anticipatory guidance, including the patient’s age, developmental stage, health status, and health literacy level. See **Box 41–8** for suggested anticipatory guidance topics.

Anticipatory guidance provided by healthcare professionals can help patients prevent health alterations or complications. Nurses can expect to use anticipatory guidance in the form of patient teaching in various settings, including:

- Prenatal visits
- Well-child/adolescent visits
- Annual medical/dental visits
- Community programs such as health screenings, health fairs, and safety programs.

Because the time for each visit is limited, nurses should build on a patient’s current knowledge and care practices and start with a topic in which the patient expresses interest. Nursing using anticipatory guidance should reinforce what the patient and family are doing well and clear up any poorly understood concepts.

Box 41–8

Topics for Anticipatory Guidance

Children and Parents

- Growth and development
- Nutrition
- Mental health issues
- Risks of secondhand smoke
- Sleep safety and patterns
- Sunscreen use
- Automobile and bicycle safety
- Family and peer stress and relationships
- Disease and injury/accident prevention

Adults

- Injury prevention strategies for mechanical equipment
- UVA/UVB protection
- Responsible sexual behaviors
- Alcohol and drug use

Older Adults

- Fall prevention
- Medication use and side effects
- Age-related nutritional needs
- Safe driving evaluations
- Advance directives

Nurses rely on resources in the community to enhance the guidance provided. For example, Bright Futures provides information for anticipatory guidance regarding children. State and local Safe Kids coalitions help inform families about injury prevention strategies. Schools provide health and safety programs throughout the year. Nurses need to be aware of the types of programs available in the community to reinforce concepts.

» **Stay Current:** Visit Bright Futures at www.brightfutures.org and Safe Kids at www.safekids.org to enhance your teaching strategies for children.

Patient Contracting

Learning contracts are mutually developed verbal or written agreements between the teacher and the learner. They are an increasingly popular, effective teaching strategy to encourage independence and control over personal health management and wellness. Essential elements include what the learner will learn, information resources and the way in which learning will be accomplished, and rewards for consistent contract adherence and goal achievement (Bastable & McLees, 2016). Use of a learning contract allows for freedom, mutual respect, and mutual responsibility.

The following is an example of a patient contract:

I, Kirsten Hugo, will exercise strenuously for 20 minutes three times per week for a period of 2 weeks and will then buy myself six yellow roses.

Kirsten Hugo
A. Tucker RN
July 30, 2017

Group Teaching

Group instruction is economical, and it provides members with an opportunity to share with and learn from others. A small group allows for discussion in which everyone can participate. A large group often necessitates a lecture technique or use of films, videos, slides, or role-playing by teachers.

All members involved in a particular group should have a common need (e.g., prenatal health or preoperative instruction). Sociocultural factors also should be considered when a group is being formed.

Technology-Assisted Instruction

Technology-assisted instruction (TAI) is increasingly popular. Initially, the primary use of computer educational methods was for cognitive learning of facts. Now, however, computers and other electronic devices (e.g., smartphones and tablets) can also be used to teach the following:

- Application of information (e.g., answering questions after reading information about a health subject)
- Psychomotor skills (e.g., filling a syringe on the computer screen to the correct dosage line)
- Complex problem-solving skills (e.g., responding to questions based on a patient situation)

TAI can also be used in various other ways. For example:

- Individual healthcare professionals or patients may use an electronic device for teaching/learning.
- Families or small groups of three to five patients may gather around one electronic device and take turns running a program and answering questions together.
- Large groups may view a display of a computer's monitor that is projected onto an overhead screen, while a teacher or a learner uses a keyboard or other device to change the display.
- Individuals or small groups may use computers or other electronic devices through shared network platforms or through websites.

Individuals using an electronic device are able to set the pace that meets their particular learning needs. Small groups are less able to do this, and large groups progress through the program at a pace that may be too slow for some learners and too fast for others. It is therefore helpful to group learners of similar needs and abilities together.

Whether using an electronic device alone or in large groups, learners read and view informational material, answer questions, and receive immediate feedback. The correct answer is usually indicated by the use of colors, flashing signs, or written praise. When the learner selects an incorrect answer, the program may respond with an explanation of why that was not the best answer and encouragement to try again. Many programs ask learners whether they want to review material on which the question and answer were based. Some programs feature simulated situations that allow learners to manipulate objects on the screen to learn psychomotor skills. When used to teach such skills, TAI must be followed up with practice on actual equipment supervised by the teacher.

Some patients may have a negative attitude about electronic devices that creates a barrier to learning. The nurse can help these patients by explaining how the device helps meet their needs. Matching a program or website to the patient's individual health circumstances may encourage the use of electronic devices. Providing a resource list of free available community sites for training and access may also help. For patients who use the internet, it is important for the nurse to teach the patient how to evaluate whether the site is a relevant, credible source for health information. In addition, it is important to recognize that some individuals still do not embrace technology. This may be due to a number of factors, including affordability, access, and literacy level.

Most media catalogs, professional journals, and health-care libraries contain information about computer software programs and mobile device applications available to the nurse for patient education. The media specialist or librarian in a healthcare facility or college is an excellent resource to help locate appropriate programs. Technological educational material is also available for patients with different language needs, for patients with special visual needs, and for patients at various growth and development levels.

Discovery/Problem Solving

In using the discovery/problem-solving technique, the nurse presents some initial information, then asks the learner a question or presents a situation related to the information. The learner applies the new information to the situation and decides what to do. Learners can work alone or in groups. This technique is well suited to family learning. The teacher guides the learners through the thinking process necessary to reach the best solution to the question or the best action to take in the situation. This may also be referred to as **anticipatory problem solving**. For example, the nurse educator might present information on diabetes and glucose management. Then the nurse might ask the learners how they think their insulin and/or diet should be adjusted if their morning glucose reading is too low. In this way, patients learn what critical components they need to consider to reach the best solution to the problem.

Behavior Modification

The basic assumptions of the behavior modification system are (a) that human behaviors are learned and can be selectively strengthened, weakened, eliminated, or replaced; and (b) that an individual's behavior is under conscious control. Under this system, desirable behavior is rewarded and undesirable behavior is ignored. The patient's response is the key to behavior change. For example, patients who are trying to quit smoking are not criticized when they smoke, but they are praised or rewarded when they go without a cigarette for a certain period of time. For some people, a learning contract is combined with behavior modification and includes the following pertinent features:

- Positive reinforcement (e.g., praise) is used.
- The patient participates in the development of the learning plan.
- Undesirable behavior is ignored, not criticized.
- The expectation of the patient and the nurse is that the task will be mastered (i.e., the behavior will change).

Teach-Back Method

With the **teach-back method**, the nurse provides teaching on a particular topic, then asks the patient to describe the main points from that teaching using his or her own words. This method is similar to return demonstration, except it requires the patient to show understanding through verbal communication instead of through actual physical performance of a task (Agency for Healthcare Research and Quality [AHRQ], 2015).

In order to successfully employ the teach-back method, the nurse should keep several points in mind. First and foremost, the nurse must provide all information in plain language that the patient can understand. The nurse should also pause periodically throughout the teaching session to check that the patient understands and remembers the material delivered so far. If the nurse asks for certain information but the patient cannot provide it or restates the information incorrectly, the nurse must clarify the areas of confusion before moving on to the next topic in the teaching session. Once the nurse has addressed all of the teaching topics, he or she should once again ask the patient to explain major points not only from the most recent part of the session, but also from earlier portions. To help increase and reinforce patient understanding throughout the session, the nurse may supplement the teach-back method with use of handouts and/or return demonstration (AHRQ, 2015).

Although the teach-back method seems simple on its surface, it requires a great deal of preparation on the part of the nurse. Not only must the nurse plan the teaching session and select language and educational materials appropriate for each patient, but he or she must also anticipate which topics are most likely to elicit confusion and necessitate further follow-up. The nurse must also practice use of this method so that it does not seem awkward or off-putting to patients or unnecessarily extend the length of the teaching session. Finally, the nurse should remember that the teach-back method is not a test of the patient's knowledge or learning capacity, but rather of how well the nurse explained the information (AHRQ, 2015).

Transcultural Teaching

Nurses and patients from different cultural and ethnic backgrounds have additional barriers to overcome in the teaching-learning process. These barriers include language and communication problems, differing concepts of time, conflicting cultural healing practices, beliefs that may positively or negatively influence compliance with health teaching, and unique high-risk or high-frequency health problems that can be addressed with health promotion instruction. Nurses should consider the following guidelines when teaching patients from various ethnic backgrounds:

- Obtain teaching materials, pamphlets, and instructions in languages used by patients. Nurses who are unable to read the foreign language material for themselves can have a translator read the material to them. The nurse can then evaluate the quality of the information and update it with the translator's help as needed.
- Use visual aids, such as pictures, charts, or diagrams, to communicate meaning. Audiovisual material may be helpful if the English is spoken clearly and slowly. Even if

understanding the verbal message is a problem for the patient, seeing a skill or procedure may be helpful. In some instances, a translator can be asked to clarify the video. Alternatively, the video may be available in several languages, and the nurse can request the necessary version from the company.

- Use concrete rather than abstract words. Use simple language (short sentences, short words) and present only one idea at a time.
- Allow time for questions. This helps the patient mentally separate one idea or skill from another.
- Avoid the use of medical terminology or healthcare language, such as "taking your vital signs" or "apical pulse." Rather, nurses should say they are going to take a blood pressure reading or listen to the patient's heart.
- If understanding the patient's pronunciation is a problem, validate brief information in writing. For example, during assessments, write down numbers, words, or phrases and have the patient read them to verify accuracy.
- Use humor very cautiously. Meaning can change in the translation process.
- Do not use slang words or colloquialisms. These may be interpreted literally.
- Do not assume that a patient who nods, uses eye contact, or smiles is indicating an understanding of what is being taught. These responses may simply be the patient's way of indicating respect. The patient may feel that asking the nurse questions or stating a lack of understanding is inappropriate because it might embarrass the nurse or cause the nurse to "lose face."
- Invite and encourage questions during teaching. Let patients know they are urged to ask questions and be involved in making information clearer. When asking questions to evaluate patient understanding, avoid asking negative questions. These can be interpreted differently by people for whom English is a second language. "Do you understand how far you can bend your hip after surgery?" is better than the negative question "You don't understand how far you can bend your hip after surgery, do you?" With particularly difficult information or skills teaching, the nurse might say, "Most people have some trouble with this. May I please help you go through this one more time?" In some cultures, expressing a need is not appropriate, and expressing confusion or asking to be shown something again is considered rude.
- When explaining procedures or functioning related to personal areas of the body, it may be appropriate to have a nurse of the same sex do the teaching. Because of modesty concerns in many cultures and beliefs about what is considered appropriate and inappropriate male-female interaction, it is wise to have a female nurse teach a female patient about personal care, birth control, sexually transmitted infections, and other potentially sensitive areas. If a translator is needed during explanation of procedures or teaching, the translator should also be female.
- Include the family in planning and teaching. This promotes trust and mutual respect. Identify the authoritative

family member and incorporate that person into the planning and teaching to promote compliance and support of health teaching. In some cultures, the male head of household is the critical family member to include in health teaching; in other cultures, it is the eldest female member.

- Consider the patient's time orientation. The patient may be more oriented to the present than the nurse. Cultures with a predominant orientation to the present include the Mexican American, Navajo Native American, Appalachian, Eskimo, and Filipino American cultures. Preventing future problems may be less significant for these patients than for others, so teaching prevention may be more difficult. For example, teaching a patient why and when to take medications may be more difficult if the patient is oriented to the present. In such instances, the nurse can emphasize preventing short-term problems rather than long-term problems. Failure to keep clinic appointments or to arrive on time is common in patients who have a present-time orientation. The nurse can help by accommodating these patients when they arrive for their appointment.

Schedules may be very flexible in present-oriented societies, with sleeping and eating patterns varying greatly. Teaching patients to take medications at bedtime or with a meal does not necessarily mean that these activities will occur at the same time each day. For this reason, the nurse should assess the patient's daily routine before teaching the patient to pair a treatment or medication with an event the nurse assumes occurs at the same time every day. When teaching a patient when to take medication, the nurse should determine whether a clock or watch is available to the patient and whether the patient can tell time.

- Identify cultural health practices and beliefs. Noncompliance with health teaching may be related to conflict with folk medicine beliefs. Noncompliance may also be related to lack of understanding or fatalism, a belief system in which life events are held to be predestined or fixed in advance and the individual is powerless to change them. Provide an opportunity for patients to explain their views and rationale for not adhering to the treatment plan or why it did not work.

The nurse should treat the patient's cultural healing beliefs with respect and try to identify whether any are in agreement or in conflict with what is being taught. The nurse can then focus on the ones in agreement to promote the integration of new learning with the familiar health practices. The goal is to arrive at a mutually agreeable plan: Decide which instructions must be followed for patient safety, then negotiate less crucial folk healing practices. See the Focus on Diversity and Culture feature for information specific to teaching Hispanic patients.

Evaluating Teaching and Learning

Evaluation is both an ongoing and a final process in which the patient, the nurse, and often the patient's support people determine what has been learned.

Focus on Diversity and Culture Teaching Hispanic Patients

Hispanic patients are a diverse and growing population with special teaching considerations. One key consideration is language. Use of interpreters is helpful for overcoming this issue, as is use of written material in the patient's native language. In addition to these techniques, the "teach-back" method is also particularly helpful. This method can be time consuming, but it has been shown to result in better understanding and adherence in Hispanic patients (Juckett, 2013).

In addition, the nurse's observance of the Hispanic cultural values of *simpatía* (kindness), *personalismo* (friendliness), and *respeto* (respect) are essential for building trust with Hispanic patients and enhancing learning (Juckett, 2013). *Simpatía* can be defined as politeness and avoidance of conflict. For example, a nurse who compliments a patient on the health maintenance practices he observes rather than criticizing him for those he does not observe is exhibiting *simpatía*. *Personalismo* is a personal connection between two people. A nurse who asks a patient about his family is showing *personalismo*. *Personalismo* is similar to the phenomenon of connectedness that was found to be important for providing culturally competent care for Hispanic patients (Sobel & Sawin, 2016). *Respeto* is concern for the individual and respect for age and experience. By calling the patient "Señor" rather than using his first name, the nurse demonstrates *respeto*.

Evaluating Learning

The process of evaluating learning is the same as evaluating patient achievement of desired outcomes for other nursing diagnoses. Learning is measured against the predetermined learning outcomes selected in the planning phase of the teaching process. Thus, the outcomes serve not only to direct the teaching plan but also to provide outcome criteria for evaluation. For example, the outcome "Selects foods that are low in carbohydrates" can be evaluated by asking the patient to name such foods or to select low-carbohydrate foods from a list.

The best method for evaluating learning depends on the type of learning. For cognitive learning, the patient should be able to demonstrate acquisition of knowledge. Examples of evaluation tools for cognitive learning include the following:

- Direct observation of behavior (e.g., observing the patient demonstrate use of a blood pressure monitor)
- Written measurements (e.g., tests)
- Oral questioning (e.g., asking the patient to restate information or correct verbal responses to questions)
- Patient reports and self-monitoring. These can be useful during follow-up phone calls and home visits. Evaluating individual self-paced learning, as might occur with computer-assisted instruction, often incorporates self-monitoring.

The acquisition of psychomotor skills is best evaluated by observing how well the patient carries out a procedure, such as self-administration of insulin.

Affective learning is more difficult to evaluate. Whether attitudes or values have been learned may be inferred by

listening to the patient's responses to questions, noting how the patient speaks about relevant subjects, and observing patient behavior that expresses feelings and values. For example, have parents learned to value health sufficiently to have their children immunized? Do patients who state that they value health actually use condoms every time they have sex with a new partner?

Following evaluation, the nurse may find it necessary to modify or repeat the teaching plan if the objectives have not been met or have been met only partially. Follow-up teaching in the home or by phone may be needed for the patient discharged from a health facility.

Behavior change does not always take place immediately after learning. Often individuals accept change intellectually first and then change their behavior only periodically (for example, a patient who knows that she must lose weight may diet and exercise off and on). If the new behavior is to replace the old behavior, it must emerge gradually; otherwise, the old behavior may prevail. The nurse can assist patients with behavior change by allowing for patient vacillation and by providing encouragement.

Evaluating the Learning Experience

It is important for nurses to evaluate their own teaching and the content of the teaching program, just as they evaluate the effectiveness of nursing interventions for other nursing diagnoses. Evaluation should include a consideration of all factors—the timing, the teaching strategies, the amount of information, whether the teaching was helpful, and so on. The nurse may note, for example, that the patient was overwhelmed with too much information, was bored, or was motivated to learn more. The patient should also evaluate the learning experience by providing feedback on what information, materials, approaches, and other elements were helpful, interesting, or confusing. To gather such information, the nurse might provide patients with a feedback questionnaire or perhaps even video learning sessions to see which aspects of the session seem to be most and least effective.

The nurse should not feel ineffective as a teacher if the patient forgets some of what is taught. Forgetting is normal and should be expected. Having the patient write down information, repeating it during teaching, giving handouts on the information, and having the patient be active in the learning process all promote retention.

Documenting

Documentation of the teaching process is essential because it provides a legal record that the teaching took place and

communicates the teaching to other health professionals. If teaching is not documented, legally it did not occur.

It is also important to document the responses of the patient and support people to teaching activities. What did the patient or support person say or do to indicate that learning occurred? Has the patient demonstrated mastery of a skill or the acquisition of knowledge? The nurse records this in the patient's chart as evidence of learning. The following is a sample of documentation charting:

SAMPLE DOCUMENTATION

11/8/2017 1130 Learning to use glucometer to check own capillary blood glucose levels. Noted a slight hesitation with each step. Demonstrated correct technique. Stated "feeling more comfortable" each time she does it but still "needs to stop and think about the process." Will continue to monitor patient's progress. *C. Brown RN*

Many agencies have multiple-copy patient teaching forms that include the medical and nursing diagnoses, the treatment plan, and the patient education. After the teaching session is completed, the patient and the nurse sign the form, and a copy of the form is given to the patient as a record of teaching and as reinforcement of the content taught. A second copy of the completed and signed form is placed in the patient's chart. The parts of the teaching process that should be documented in the patient's chart include the following:

- Diagnosed learning needs
- Learning outcomes
- Topics taught
- Patient outcomes
- Need for additional teaching
- Resources provided.

The written teaching plan that the nurse uses as a resource to guide future teaching sessions might also include these elements:

- Actual information and skills taught
- Teaching strategies used
- Time framework and content for each class
- Teaching outcomes and methods of evaluation.

Nursing Care Plan

A Patient Who Requires Teaching About Wound Care

Kevin McArthur is a 22-year-old male college student who received a laceration on his leg while playing in an intramural hockey game. During the game, Kevin became entangled with another player. He fell as a result of the encounter and landed on the other player's skate blade.

Kevin indicates that the injury occurred two nights ago and that it is no longer bleeding. He tells you that he does not think the wound is a "big deal," but came to the health center today at his roommate's insistence. He also admits to you that he is a little embarrassed that his "clumsiness" has resulted in this injury.

Nursing Care Plan (continued)

ASSESSMENT	DIAGNOSES	PLANNING
Kevin is alert and oriented. He tells you he lives in a dormitory on campus and confirms that he is able to understand, read, and write English. He seems distracted, bored, and uninterested in performing wound self-care. You check his vitals and make the following assessments: T _o 38.7°C (101.6°F); P 66 beats/min; R 17/min; BP 115/74 mmHg. Kevin's weight is 85 kg (187.4 lb) and within normal limits for his height. Physical examination reveals a 7-cm (2.5-in) laceration on the left lower anterior leg. There is redness and minor swelling around the laceration. You also note the presence of serous exudate.	<ul style="list-style-type: none"> ■ <i>Impaired Skin Integrity</i> ■ <i>Risk for Infection</i> related to alteration in skin integrity ■ <i>Deficient Knowledge</i> of care of sutured wound related to lack of prior experience (NANDA-I © 2014)	<ul style="list-style-type: none"> ■ The patient will describe normal wound healing. ■ The patient will identify three main signs and symptoms of infection. ■ The patient will identify supplies needed for wound care. ■ The patient will correctly perform a return demonstration of wound cleansing and bandaging. ■ The patient will describe appropriate action if questions or complications arise. ■ The patient will identify date, time, and location of follow-up appointment for suture removal.

IMPLEMENTATION

- Assist the healthcare provider with cleansing, suturing, and dressing the wound as ordered.
- Describe normal wound healing and provide written and visual instructions of the signs and symptoms of local infection and complications, including increased redness, swelling, purulent drainage, and pain at wound site. Discuss the symptoms of systemic infection, including fever and malaise.
- Identify and provide wound care supplies such as bandaging material (e.g., gauze wrap, nonadhesive pads, adhesive tape) and cleansing solution as prescribed by provider (e.g., mild soap and water, antimicrobial solution, triple-antibiotic ointment).
- Demonstrate wound cleansing and bandaging on the patient's wound. Remove wound dressings and have the patient perform return demonstration. Provide a written handout describing the procedure.
- Instruct on appropriate actions and follow-up if questions or complications occur. Provide written instructions listing available resources, clinic contact information, and treatment plan. Include the date, time, and location of next follow-up appointment in 10 days in written instructions.

EVALUATION

At the 10-day follow-up appointment, Kevin reports that he has forgotten to clean the wound and change the dressing "a few times." The dressing on his leg is clearly several days old and was haphazardly applied. His wound shows signs of local infection, including thick yellow discharge, redness, and swelling. Kevin's temperature

is also elevated. The healthcare provider diagnoses Kevin with an abscess. His stitches are removed and the wound is drained. Kevin is prescribed a 2-week course of antibiotics. He is also advised to soak the infected area with warm towels three times per day to aid the healing process.

CRITICAL THINKING

1. Discuss Kevin's readiness to learn at his initial appointment and describe indicators of his level of readiness. How might the nurse enhance his readiness to learn?
2. What are the priority learning outcomes for Kevin at his follow-up appointment? Which teaching methods might improve his compliance with the treatment regimen?
3. How would you handle the situation if Kevin continues to show a lack of interest in self-wound care in spite of the changes to your teaching methods?

REVIEW Patient/Consumer Education

RELATE Link the Concepts and Exemplars

Linking the exemplar of patient/consumer education with the concept of development:

1. How does the concept of development impact teaching and learning?
2. How should the nurse incorporate characteristics of each developmental stage when choosing teaching strategies?

Linking the exemplar of patient/consumer education with the concept of culture and diversity:

3. What aspects of culture should be considered before developing a teaching plan for a patient?
4. How should the nurse address teaching and learning when a patient's health beliefs and values differ from his or her own?

Linking the exemplar of patient/consumer education with the concept of cognition:

5. How should the nurse address teaching and learning for a patient with altered cognition?
6. How does the concept of cognition impact the nurse's teaching plan and the patient's learning?

REFLECT Apply Your Knowledge

Mrs. Yorty is a 59-year-old female bank vice president who is heavily relied on by her boss and coworkers. Three days ago, she was admitted to the hospital with complaints of shortness of breath and mild chest pain. A diagnostic evaluation indicates that she has significant coronary artery disease but has not yet had a heart attack. Her primary care provider has indicated that Mrs. Yorty will need to make significant lifestyle changes to reduce her heart attack risk.

As her nurse, you have been asked to teach Mrs. Yorty about her disease process, diet, exercise, and stress reduction. As you begin teaching Mrs. Yorty, you note that she is very pleasant and frequently nods her head, but she also seems preoccupied and is easily distracted.

1. How would you evaluate Mrs. Yorty's readiness to learn?
2. Of what benefit would a learning needs assessment be since Mrs. Yorty is obviously a well-educated patient?
3. You recognize that you have a great deal of information to deliver to Mrs. Yorty, and you are concerned that you will not be able to teach it all. What can you do to help Mrs. Yorty and still accomplish the learning outcomes?
4. How will you know if your teaching is effective?
5. How might your teaching differ if you were teaching Mrs. Yorty at home rather than in a hospital or acute care setting?

Part V

Healthcare Domain

Part V consists of modules that outline and define principles related to the healthcare domain, including accountability, ethics, and quality improvement. Each module presents a concept that relates directly to professional nursing, its relationship to healthcare systems and policies, and how nursing within the healthcare system impacts patient health and well-being. Selected

principles or topics of each concept are presented as exemplars. The exemplars in the module on Accountability, for example, cover Competence and Professional Development. Each module addresses the effect of that concept and the selected exemplars on the care of individuals across the lifespan, inclusive of their culture, their gender, and their developmental status.

Module 42 Accountability 2695

Module 43 Advocacy 2715

Module 44 Ethics 2729

Module 45 Evidence-Based Practice 2761

Module 46 Healthcare Systems 2775

Module 47 Health Policy 2797

Module 48 Informatics 2809

Module 49 Legal Issues 2827

Module 50 Quality Improvement 2857

Module 51 Safety 2871

Module 42

Accountability

Module Outline and Learning Outcomes

The Concept of Accountability

Components of Accountability

42.1 Analyze how the nursing profession promotes accountability.

Concepts Related to Accountability

42.2 Outline the relationship between accountability and other concepts.

Socialization to Nursing

42.3 Analyze the process of socialization to nursing.

Factors Influencing Nursing Practice and Accountability

42.4 Differentiate factors that influence nursing practice and accountability.

Accountability Exemplars

Exemplar 42.A Competence

42.A Analyze competence as it relates to accountability.

Exemplar 42.B Professional Development

42.B Analyze professional development as it relates to accountability.

Accountability and responsibility are words that are often used interchangeably. However, they have some important distinctions. **Accountability** involves being answerable for the outcomes of a task or assignment. Nurses are accountable for their own actions and behaviors, but they may also be accountable for the actions of others, such as subordinates or trainees. **Responsibility** is the specific obligation associated with the performance of duties of a particular role, and it belongs to the individual performing the duties. Nurses are responsible for performing their assigned tasks reliably, dependably, and to the best of their abilities. Nurses' sense of accountability guides their performance, which ultimately determines patient outcomes.

Accountability in nursing cannot be achieved without clear definitions of what is an accepted standard of care. **Standards of care**, also known as **standards of practice**, are professional standards or guidelines used to determine what a nurse should or should not do. These standards are established by organizations such as The Joint Commission, the American Nurses Association (ANA), and the National League for Nursing (NLN). They describe the responsibilities for which nurses are accountable, thereby setting a

desirable and achievable benchmark against which the performance and care standards of individual nurses may be measured (Davis, 2014). For example, a standard of practice/care for medication administration set forth by The Joint Commission is to require two patient identifiers prior to giving the prescribed dose. A nurse who chooses not to meet this requirement is failing to practice at the minimum standard acceptable to the profession and will be held accountable to the patient and the facility for which he or she works.

As another example, suppose a nurse has a patient who will need continued wound care for his left foot after discharge to home. The patient has said that he thinks he understands the procedure for changing his dressing and has promised to call if he needs any further teaching. The nurse knows that the standards of care dictate asking the patient to demonstrate how to change the dressing so that the nurse can evaluate the patient's understanding and ability to care for himself. The nurse must decide whether to allow the patient to go home without seeing him perform the dressing change or whether discharge needs to be delayed until the patient can demonstrate his understanding. In this scenario, the nurse is responsible for upholding the standards of care

and is accountable for making the decision regarding discharge of this patient. Furthermore, if the patient does not perform the dressing care properly at home and is readmitted for complications, the nurse will be responsible for that particular outcome and may be held accountable. As an alternative to the patient's demonstrating the dressing change, the nurse could opt for one of the following courses of action:

- Request an order for home healthcare to continue the teaching and follow up until the patient is comfortable on his own.
- Teach a family member to perform the dressing change in case the patient is not feeling well enough to do it on his own.
- Arrange for the patient to travel to an outpatient nursing facility for daily dressing changes.

Regardless of the chosen method, the nurse is accountable at discharge for ensuring that the patient can get his wound dressed as often as the order advises. The patient must rely on the nurse's judgment for the most favorable outcome.

Unfortunately, the term *accountability* often carries a negative connotation. When an error is made, the question "Who is accountable?" often translates into "Who is to blame?" The implication is that someone has failed. The negative image of accountability is what the public tends to see, especially since the release of *To Err Is Human* (1999), a landmark report by the Institute of Medicine (IOM). In the years since that report, healthcare organizations have worked hard to regain the public's trust. Organizations such as The Joint Commission, NLN, and ANA have revised and created standards for nurses to follow independently and jointly to ensure delivery of the safest, most competent care possible. More recently, the Robert Wood Johnson Foundation sponsored Quality and Safety Education for Nurses (Cronenwett, Sherwood, & Gelmon, 2009; QSEN, 2014), an initiative to improve quality and safety in prelicensure nursing programs. This initiative endorsed the idea that quality and safety education must become core competencies embedded in all programs that prepare nurses for basic practice. Indeed, according to QSEN (2014), the six competencies critical to the nursing role are patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics.

» **Stay Current:** To learn more about the QSEN competencies, visit the QSEN Institute website at <http://qsen.org/>.

Research supports the importance of accountability in preventing errors as well as after making them (Flynn et al., 2012). However, if nurses practice in a positive and supportive environment and celebrate accountability for their successes as well as their errors, the culture of the profession will remain positive. Thus, focusing on and honoring successes are as important as examining and correcting errors.

Components of Accountability

Nursing as a profession embraces and promotes personal and professional accountability. Aspects of the profession that promote accountability include:

- The requirement to successfully complete exhaustive, specialized training to acquire the body of knowledge necessary for performance of the role;
- The direction of the professional individual toward service, whether in a community or an organizational capacity;
- Allegiance to a code of ethics;
- The autonomy of the role; and
- Membership in a professional organization.

These factors are described in greater detail in the sections that follow.

Specialized Education

Specialized education is an important aspect of professional status. Today, entry into registered nursing in the United States is open to any individual who successfully earns either a hospital diploma or an associate's, bachelor's, master's, or doctorate degree in nursing and subsequently passes the National Council Licensure Examination, or NCLEX. Fewer than 70 hospitals around the country still offer diploma programs, so the vast majority of new RNs hold either an associate's or bachelor's degree (NLN, 2014; Salsberg, 2015). The ANA recommends a bachelor's degree to enter professional practice, and many magnet hospitals and academic health centers require that their RNs have at least a bachelor's degree. Thus, many associate's degree RNs later opt to pursue their bachelor's degree, typically through participation in an RN-to-BSN program that builds on their existing knowledge and skill set. Similarly, many bachelor's degree RNs go on to earn a master's or doctorate degree in order to further advance in their careers (American Association of Colleges of Nursing, 2015).

Body of Knowledge

As a profession, nursing has a well-defined body of knowledge and expertise that is always expanding. This knowledge base is the product of various conceptual nursing frameworks that direct practice, education, and ongoing research. The nursing profession continues to grow and develop its body of knowledge over time, maintaining an evidence-based practice based on current research that promotes accountability for safe nursing practice (see the Evidence-Based Practice feature).

Service Orientation

A service orientation means that nursing, unlike some occupations, is not primarily driven by considerations of profit. Rather, nursing emphasizes service to others as a matter of tradition and as a basis for accountability. Rules, policies, and codes of ethics guide and shape this tradition of service. Nursing has been and continues to be an integral component of the system for delivering healthcare.

Evidence-Based Practice

Leadership Interventions to Establish Evidence-Based Practice

Problem

What is the impact of leadership facilitation strategies on nurses' beliefs about the importance and frequency of using evidence in their daily practice? How can nursing leaders encourage nurses to adopt evidence-based practice (EBP) methods?

Evidence

In one study by Hauck, Winsett, and Kuric (2013), a 429-bed non-teaching, faith-based hospital located in a moderate-sized city in the Midwest conducted a prospective descriptive comparative study that involved three surveys. The Evidence-Based Practice Beliefs Scale, the Implementation Scale, and the Organizational Culture and Readiness for System-Wide Integration Survey measured change before and after facilitation of strategies for EBP enculturation. They found that the hospital's nursing leadership facilitated infrastructure development in three major areas: incorporating EBP outcomes in the strategic plan; supporting mentors; and advocating for resources for education and outcome dissemination. Following interventions in these areas, nurses' total group scores regarding their belief in the value of EBP improved significantly. Hauck et al. (2013) concluded that the most successful strategies for changing nurses' perceptions of EBP and organizational readiness were EBP education and establishing internal opportunities to disseminate findings. They also noted that transformational nursing leadership drives organizational change and provides vision, human and financial resources, and time that empowers nurses to include evidence in practice.

Several years later, another study (Guerrero et al., 2016) used semistructured interviews and surveys to identify the approaches used by leaders of addiction treatment centers when implementing EBP methods in their facilities. In their study, Guerrero et al. (2016)

determined that the top strategies for encouraging staff to use EBP techniques involved the "recruitment and selection of staff members receptive to change, offering support and requesting feedback during the implementation process, and offering in-vivo and hands-on training." Leadership behaviors that encouraged EBP techniques included being proactive to implementation needs, supportive to staff members, knowledgeable to guide the implementation process, and willing to address ongoing barriers to EBP implementation.

Implications

Because of the continual nursing shortage, healthcare facilities must recruit and retain competent nursing staff, as well as effectively implement evidence-based changes in the practice environment. Studies such as those by Hauck et al. (2013) and Guerrero et al. (2016) provide insight as to the most effective methods for making EBP part of an organization's nursing culture. In doing so, they also highlight strategies that can be used to improve nursing practice and prevent errors—thereby contributing to higher-quality patient care, better nursing retention, and lower costs.

Critical Thinking Application

1. In the study by Hauck et al. (2013), nurses were encouraged to search for evidence to support their daily practice. How have you been encouraged to use evidence-based research findings as a nursing student?
2. Although not discussed in these particular studies, from the authors' findings, what role could nursing education programs take in assisting with EBP implementation in acute care nursing units where student nurses are practicing?

Code of Ethics

Another important part of the nursing tradition is respect for the inherent worth and dignity of all people. To preserve this value, professionals in the nursing field must do what is considered right, even if doing so means they incur a personal cost. In other words, nurses must strive to maintain their integrity.

As the needs and values of society change, so do its ethical codes. To promote accountability in the use of ethical behaviors, the nursing profession has developed its own codes of ethics specific to the aims of nursing and the problems that nurses typically face. These codes are discussed in detail in the module on Ethics.

Autonomy

Generally speaking, **autonomy** means independence or freedom; thus, a profession is autonomous if it is able to regulate itself and set standards of practice for its own members. One of the purposes of a professional association is to give its members autonomy. Professional status for nursing hinges to a large degree on the nursing profession's ability to function autonomously in how it formulates nursing policy and controls its own activity. Professional autonomy involves legal authority; a professional group is autonomous only if it possesses the legal authority to define its goals and responsibilities in how it delivers its services, describe its particular functions and roles, and

determine its scope of practice. With respect to the autonomy of the nursing profession, state Boards of Nursing (detailed in the module on Legal Issues) hold this legal authority.

Autonomy for nurses on an individual level means professional responsibility, accountability for their actions, and the freedom to do their jobs as necessary while at work. Nurses at all levels of practice take accountability for their actions when they advocate for their own autonomy and for that of their nurse colleagues.

Professional Organization

Professions are different from occupations in that they operate under the umbrella of a professional organization. This organizational structure provides **governance**, which establishes and maintains social, political, and economic arrangements that give professionals the means to control their professional affairs, including their practice, self-discipline, and working conditions. The module on Health Policy fully describes the professional organizations that govern and differentiate the profession of nursing.

Concepts Related to Accountability

Because accountability is a key aspect of professional nursing, it affects all areas of nursing practice. On a basic level, nurses are answerable for ensuring that patients' essential health and

Concepts Related to Accountability

CONCEPT	RELATIONSHIP TO ACCOUNTABILITY	NURSING IMPLICATIONS
Comfort	The nurse is accountable for assessing the patient's level of comfort and providing effective interventions to promote or maintain patient comfort.	<ul style="list-style-type: none"> Assess patient's reported level of comfort at least once per shift, or more often as indicated by patient's condition. Document patient's comfort level and any nursing interventions provided.
Evidence-Based Practice	The nurse is accountable for practice within an EBP environment and for implementing evidence in his or her own practice.	<ul style="list-style-type: none"> Develop a clinical question using the format described in the EBP Concept. Conduct a literature search for current evidence. Select appropriate nursing interventions based on evidence from the literature search.
Health, Wellness, Illness, and Injury	The nurse is accountable for assessing the patient's current level of health and wellness, then providing teaching, interventions, and referrals aimed at preserving and/or promoting health and preventing illness.	<ul style="list-style-type: none"> Assess patient's current overall health, including biophysical, cognitive, psychologic, and spiritual components. Provide teaching on general health promotion and illness prevention measures beneficial to all individuals (e.g., regular exercise, immunizations), as well as measures specific to the patient's risk factors and lifestyle (e.g., smoking cessation, heart-healthy diet). Refer patients to counselors, clergy, dietitians, physical therapists, support groups, and other outside resources as appropriate.
Safety	The nurse is accountable for keeping patients safe within the healthcare environment, as well as for teaching patients ways to reduce the risk of illness and injury in their daily lives.	<ul style="list-style-type: none"> Identify and address safety hazards in the immediate healthcare environment. Assess patients' risk for various types of injury outside the healthcare environment. As appropriate, teach patients about actions that can reduce their risk of injury (e.g., helmet use when bicycling, proper use of child safety restraints).
Teaching and Learning	<p>The nurse is accountable for patient education concerning all aspects of care.</p> <p>The nurse is accountable for staying up to date with the latest evidence for best practices.</p> <p>The nurse is accountable for providing current and accurate teaching to subordinates, especially nursing leaders who are mentoring nursing students.</p>	<ul style="list-style-type: none"> Assess patient and family learning needs. Assess readiness for learning. Design and implement appropriate educational interventions. Read current journal articles and attend workshops or seminars that provide up-to-date information about procedures, medications, and other standards of practice.
Trauma	Patients may present with signs or symptoms of trauma, and/or they may be at risk for abuse or violence. The nurse is accountable for taking action to prevent further harm; in some circumstances, the nurse may also have a legal duty to report.	<ul style="list-style-type: none"> Assess for signs of prior physical, emotional, or sexual abuse as part of the admission process. Assess for both risk of abuse and suicide risk as part of the admission process. Be aware of warning signs of abuse or suicide that may be demonstrated or verbalized by patients.

wellness needs are addressed. This means the nurse is accountable for providing information about measures that protect and promote patients' physical health, such as preventive screenings, recommended immunizations, smoking cessation, adequate exercise, and a healthy diet. It also means that nurses must address the cognitive, psychologic, and spiritual dimensions of health, examples of which include teaching

patients about stress management and making referrals to counselors, clergy, and similar resources as needed.

Beyond issues of health and wellness, nurses are also accountable for certain physical outcomes of patient care. These vary depending on setting, the patient's condition, state nurse practice acts, and healthcare providers' orders. Still, there are some things for which nurses are nearly

always answerable. For example, in the hospital setting, nurses are typically accountable for ensuring that patients receive appropriate fluids and nutrition, have an environment that permits adequate rest and sleep, maintain appropriate oxygenation levels, and receive assistance with elimination if necessary. Similarly, all nurses are accountable for promoting patient safety. This encompasses not just maintaining a safe physical environment within the health-care setting, but also teaching patients about ways to reduce their risk of injury in various aspects of their daily lives. Helping patients maintain comfort (or at least achieve a manageable level of pain) is a related concern. Indeed, encouraging patients to give voice to any needs and providing appropriate comfort interventions are major accountability roles for nurses in their own right, and they also help promote a safer care environment.

Yet another key area of nursing accountability relates to trauma. Per both legal requirements and the ethical standards of the profession, nurses have a duty to report certain types of trauma to the proper authorities. This includes known and suspected abuse of children and the elderly, as well as certain categories of violence-related injuries (e.g., gunshot wounds); exact requirements vary from state to state. Nurses must also continually remain aware of the potential for abuse of any vulnerable child or adult with whom they come into contact during their practice. Nurses are further accountable for preventing patients from engaging in self-directed violence, which means they must routinely assess patients for factors that may indicate an increased risk of self-harm, suicide, and suicidal intent.

Because teaching is a critical nursing function, it too is an important area of accountability—and one that extends to all patient care areas. As previously mentioned, nurses must provide patients with broad-based information about health, illness, and safety, but they are also accountable for educating patients about tests, procedures, diagnoses, treatments, and other self-care measures specific to their condition. In order to provide such teaching, nurses must first assess each patient's learning style and readiness to learn. Nurses are also accountable for their own ongoing education and professional development. This encompasses not just meeting state and institutional continuing education requirements, but also taking steps to apply what they have learned via evidence-based practice.

The Concepts Related to Accountability feature links some, but not all, of the concepts integral to accountability. They are presented in alphabetical order.

Case Study » Part 1

Jen Sturges is a new RN on the medical unit in a 245-bed hospital. During the evening shift, Jen starts her rounds with her five patients. One of her patients is a 45-year-old woman named Kathryn Miller, who has been admitted with a GI diagnosis and also has a history of back pain. During Jen's assessment of her pain level, Ms. Miller says she is "doing just fine," although she seems very anxious. As Jen reviews Ms. Miller's vital signs, which the CNA had recently taken, she notes a blood pressure much higher than usual. Jen comments that one of the symptoms of pain is elevated blood pressure. Ms. Miller describes trying to overrule her body by ignoring its signals and by having a dialogue between the "body me" and the "real me." Ms. Miller also states, "If I refuse to pay attention to my body, my pain will go away."

Jen realizes that Ms. Miller, although actually in pain, might not be allowing herself to pay attention. Jen asks Ms. Miller if she has discussed pain management with her primary healthcare provider. Ms. Miller laughs: "My doctor tries to have me take narcotics, but I worry about those types of meds." As she speaks, Ms. Miller's hands are gripping the bed sheets and she is shaking. She says, "The pain is my enemy, and I don't talk to my enemies."

Jen knows that ignoring the body's signals of pain can cause serious consequences; for example, the pain could intensify and the patient's blood pressure could rise significantly. Jen also realizes that Ms. Miller needs to get appropriate treatment for her pain. After her assessment, Jen discusses her concerns about Ms. Miller with the unit charge nurse, including Ms. Miller's need for pain management and comfort.

Clinical Reasoning Questions Level I

1. Why is it important for Jen to complete her patient's assessment before leaving the room?
2. What further symptoms does Jen observe while she speaks with her patient?
3. What information should Jen share with the charge nurse to assist in meeting her patient's needs?

Clinical Reasoning Questions Level II

4. With what staff should Jen and the charge nurse plan to collaborate to find a better method for managing Ms. Miller's pain?
5. When a patient refuses pain management, why should the nurse pursue other solutions rather than simply acquiescing?

Socialization to Nursing

As previously mentioned, the members of a profession—and not outsiders—determine the standards of education and practice for that profession. Entering a profession is therefore similar to entering a new society, so it involves a complete socialization process far more extensive than what most nonprofessional occupations require. Socialization into a profession supports accountability because it has consequences for the nurse by instilling critical values and providing opportunities for interactions that support and promote accountability.

Socialization is the process by which individuals learn to become members of groups and society as well as learn the social rules defining the relationships into which they will enter. In a traditional sense, socialization involves learning how to behave, feel, and see the world in your chosen role as others do in that same role (Hardy & Conway, 1988). Professional socialization is a more complex process. Dinmohammadi et al. (2013) conducted a meta-analysis to clarify the process of professional socialization and to identify its attributes, antecedents, and consequences in nursing. They argue that professional socialization is a complex process with four critical attributes: learning, interaction, development, and adaptation. Comprehensive educational programs, competent faculty and role models, and adequate field experiences were found to be the antecedents of these attributes. Additional research by Price (2009) further underscores the need for mentors and peers in nursing.

Interaction with fellow students is a powerful driver for professional socialization among nursing students (Fettig & Friesen, 2014; Houghton, 2014). Through this interaction, students naturally and collectively set norms for and determine

Box 42–1

National Student Nurses Association Code of Academic and Clinical Conduct

Preamble

Students of nursing have a responsibility to society in learning the academic theory and clinical skills needed to provide nursing care. The clinical setting presents unique challenges and responsibilities while caring for human beings in a variety of healthcare environments.

The Code of Academic and Clinical Conduct is based on an understanding that to practice nursing as a student is an agreement to uphold the trust that society has placed in us. The statements of the code provide guidance for the nursing student in the personal development of an ethical foundation and need not be limited strictly to the academic or clinical environment but can assist in the holistic development of the individual.

A Code for Nursing Students

As students are involved in the clinical and academic environments we believe that ethical principles are a necessary guide to professional development. Therefore within these environments we:

1. Advocate for the rights of all clients.
2. Maintain client confidentiality.
3. Take appropriate action to ensure the safety of clients, self, and others.
4. Provide care for the client in a timely, compassionate and professional manner.
5. Communicate client care in a truthful, timely and accurate manner.
6. Actively promote the highest level of moral and ethical principles and accept responsibility for our actions.
7. Promote excellence in nursing by encouraging lifelong learning and professional development.
8. Treat others with respect and promote an environment that respects human rights, values, and choice of cultural and spiritual beliefs.
9. Collaborate in every reasonable manner with the academic faculty and clinical staff to ensure the highest quality of client care.
10. Use every opportunity to improve faculty and clinical staff understanding of the learning needs of nursing students.
11. Encourage faculty, clinical staff, and peers to mentor nursing students.
12. Refrain from performing any technique or procedure for which the student has not been adequately trained.
13. Refrain from any deliberate action or omission of care in the academic or clinical setting that creates unnecessary risk of injury to the client, self, or others.
14. Assist the staff nurse or preceptor in ensuring that there is full disclosure and that proper authorization is obtained from clients regarding any form of treatment or research.
15. Abstain from the use of alcoholic beverages or any substances in the academic and clinical setting that impair judgment.
16. Strive to achieve and maintain an optimal level of personal health.
17. Support access to treatment and rehabilitation for students who are experiencing impairments related to substance abuse and mental or physical health issues.
18. Uphold school policies and regulations related to academic and clinical performance, reserving the right to challenge and critique rules and regulations as per school grievance policy.

Note: This code was adopted by the NSNA House of Delegates, Nashville, Tennessee, on April 6, 2001. Reprinted with permission.

the direction of their scholastic efforts. They develop perspectives about the situations in which they are involved, the goals they are trying to achieve, and the kinds of activities and behaviors that are appropriate for nurses, and they establish a set of practices in keeping with all of these things. Students become bound together by feelings of mutual cooperation, support, and solidarity that continue after they graduate and enter the world of professional nursing.

Nursing education aids students in the development of individual professional values by helping them clarify and internalize these values. The nursing code of ethics (described in the module on Ethics), standards of nursing practice (described in the exemplar on Professional Development in this module), and the legal system itself (described in the module on Legal Issues) define specific values all professional nurses should share. The National Student Nurses Association (NSNA) also adopted a code of academic and clinical conduct in 2001 (**Box 42–1** ») that is an integral part of ethical practice (NSNA, 2013). This code addresses students' responsibility in the academic environment and to society at large as they learn clinical skills in nursing care.

Case Study » Part 2

Jen Sturges meets with the charge nurse, Melinda Menendez, and briefly but clearly discusses her concerns about Ms. Miller's pain management and the objective signs she noted during her shift. Ms.

Menendez asks Jen what she thinks is going on with Ms. Miller. Jen tells her that this is her first experience with a patient who has a history of pain but does not want to use any pain medications and ignores her apparent pain.

Ms. Menendez is concerned that Ms. Miller would be unable to participate in her care and other daily activities if she has uncontrolled pain during hospitalization. She asks Jen to join her while she speaks with Ms. Miller. After a few minutes of discussion, it becomes clear that Ms. Miller is afraid of the potential for narcotic abuse. It also appears that uncertainty about the meaning of her body's pain signals worries Ms. Miller about the safety of her physical activities at home and in the hospital. Ms. Menendez gently holds Ms. Miller's hand and tells her how important it is for her to take part in care activities and to allow the staff to manage pain and keep her as comfortable as possible. "To help you with this care," Ms. Menendez says, "I would like our social worker and clinical pharmacist to see you about your pain and other needs while you are here." Ms. Miller agrees with this plan.

Clinical Reasoning Question Level I

1. As the charge nurse, Ms. Menendez took an active role in further assessment of the patient's needs and communicated with Ms. Miller in a truthful and calm manner. Of what aspect of the ethical principles listed in the Code for Nursing Students is this an example?

Clinical Reasoning Question Level II

2. If Jen had waited to collaborate with Ms. Menendez, would this have prevented further care and appropriate patient outcomes? Explain your answer.

Factors Influencing Nursing Practice and Accountability

Various factors influence nursing as a profession, and because of the integral part nursing plays in the healthcare system as a whole, these factors typically also influence the entire healthcare system. Essentially, what affects the healthcare system will affect nursing as a profession, and the reverse is also true. Some of the most important factors affecting nursing practice include economics, consumer demand, science and technology, information availability and telecommunications, legislation, demographics, and the current nursing shortage.

Economics

In recent years, changes in public and private health insurance programs, particularly Medicare, have affected the demand for nursing care. Multiple and ongoing changes in the American healthcare system present challenges to both nurses and the organizations in which they practice. For many years, the healthcare industry has been shifting its emphasis from inpatient to outpatient care with preadmission testing, increased outpatient same-day surgery, post-hospitalization rehabilitation, home healthcare, health maintenance, physical fitness programs, and community health education programs. As a result, while acute care remains the primary nursing practice area, more nurses are being employed in community-based health settings, such as home health agencies, hospices, and community clinics.

Focus on Integrative Health Integrative Health and Accountable Care Organizations

According to the Centers for Medicare and Medicaid Services (CMS), accountable care organizations (ACOs) are groups of doctors, hospitals, and other healthcare providers that come together voluntarily to give coordinated high-quality care to their Medicare patients. The goal of an ACO is ensuring that patients, especially the chronically ill, get the right care at the right time, while avoiding unnecessary duplication of services and preventing medical errors (CMS, 2015). The linkage of healthcare institutions through ACOs ensures that healthcare providers in all phases of a patient's care are accountable to the core goal: ensuring the patient's health.

Integrative health techniques have a unique ability to serve the three-part aim of ACOs: improving the health of the population, enhancing the patient experience of care, and reducing the per capita cost of care. Integrative health strategies focus on the whole person, not just the disease, and emphasize preventive care, thus improving the health of the population. Surveys reveal that they increase patient satisfaction, thus enhancing the experience of care. Furthermore, these strategies reduce the overall cost of healthcare compared with traditional therapies alone, thus reducing the per capita cost of care (CHP Group, 2014). In fact, Davis et al. (2013) have found that "the inclusion of integrative health providers in new delivery systems such as accountable care organizations could help slow growth in national healthcare spending," providing an enticing salve to rising healthcare costs.

These changes affect nursing education, nursing research, and nursing practice, particularly with regard to the nurse's competence to practice within these settings.

As with acute care environments, the field of outpatient care has developed specialty areas to meet patient needs. For example, there are now outpatient facilities dedicated to such things as oncology symptom management, ostomy care, diabetes management, and palliative care for terminally ill patients. Various models of integrative care have also arisen in an attempt to better control rising healthcare costs, as described in the Focus on Integrative Health feature.

Consumer Demand

A **consumer** is any person or group that uses a service or commodity; thus, a consumer might be an individual, a group of individuals, or even an entire community. Because everyone has healthcare needs, the consumers of nursing services are the general public. Consumer needs are a driver for any market or service. For example, the drive for integrative healthcare services is motivated by more than the need to consolidate and lower the costs of healthcare; it is also motivated by consumer interest in the use of complementary health approaches. In a 2012 survey, nearly 18% of adults reported using a nonvitamin, nonmineral dietary supplement (Clark et al., 2015). Another factor affecting consumer use of the healthcare system is that today's healthcare consumers are more knowledgeable and vocal about their needs, in part due to the increasing amount of information available on the internet.

Science and Technology

Advances in science and technology greatly affect nursing practice, competence, and accountability. For example, recent progress in the field of molecular genetics has made it possible to identify individuals who are at elevated risk for a variety of hereditary diseases. However, the testing of healthy children for diseases that would develop only in adulthood raises many important ethical, legal, and social questions. These questions are further amplified by the fact that genetic testing is now available outside the traditional healthcare system, often without the mediation of physicians, nurses, or other healthcare professionals. Nurses therefore need to expand their knowledge base and technical skills as they adapt to meet new patient needs emerging out of the expanded use of technology.

Science and technology have affected other areas of nursing practice as well. Healthcare practitioners in most settings are now expected to learn how to use technologic advances such as sophisticated computerized equipment to monitor or treat patients. They are also expected to be able to use online Electronic Health Report Systems (CMS, 2016). In both acute inpatient settings and primary care practices, healthcare practitioners have integrated electronic health records (EHRs) successfully and have reported increased efficiency in retrieving medical records, storing patient information, and coordinating care and general office operations (Goldberg et al., 2012).

Technologic innovations have also had dramatic effects on nurses' clinical training. Simulation-based training activities are increasingly common, and they have been shown to

improve clinical decision making and have an overall positive impact on student learning and patient safety (Lafond & Van Hulle Vincent, 2013; Secomb, McKenna, & Smith, 2012; Spooner, Hurst, & Khadra, 2012). As technologies continue to change, nursing education must also continue to evolve so that nurses have the knowledge and experience necessary to provide safe, effective care.

Information Availability and Telecommunications

Increased use of the internet has dramatically affected health care, particularly as more patients become well informed about their health concerns. With easy access to the internet at home and on mobile devices, ever-greater numbers of patients and caregivers are searching the web for answers to their health questions. For instance, by 2012, 81% of American adults used the internet, 72% searched the web for health information, and 45% reported owning and using smartphones. Furthermore, many Americans regularly logged on to online forums surrounding their particular concerns (Fox, 2013).

As the internet has evolved, so have various forms of **telecommunication**, or the means by which information is transferred from one site to another via cable, radio, and other systems. Today, videoconferencing, telepractice, telerehabilitation, and virtual visits all allow individuals and/or groups in two or more locations to communicate by simultaneous two-way video and audio transmissions. It is now even possible to monitor critical care patients in an ICU in a different city or rural area and to manage patient care from another part of the world. Education has also been enhanced

by web-based distance learning. Technology-delivered education has been shown to augment existing curricula by increasing students' access to clinical experts in specialty areas, thus supporting more efficient use of faculty resources (American Telemedicine Association [ATA], 2012). As the use of **telehealth**, the provision of long-distance healthcare through the use of technology such as videoconferencing, computers, or telephones, continues to grow, **telenursing**, the provision of care via telecommunication systems, will also continue to expand.

Legislation

Changes in health legislation affect not just the nursing profession, but also consumers. The **Patient Self-Determination Act (PSDA)**, for example, requires that all competent adults be informed in writing upon admission to a healthcare institution about their rights to accept or refuse medical care and to use advance directives (American Bar Association, 2017). In many institutions, nurses are responsible for ensuring compliance with this law, as well as with similar regulatory requirements. In this way, legislative and other regulatory changes can directly affect the nurse's role in supporting patients and their families.

The Current Nursing Shortage

The present nursing shortage involves multiple new factors (**Box 42-2**) that did not contribute to previous nursing shortages. For example, even though registered nurses make up the largest group of healthcare providers, fewer nurses are entering the workforce now, and certain geographic

Box 42-2

Factors Contributing to the Nursing Shortage

Nursing School Enrollment Not Growing Fast Enough

- There was a 2.6% increase in entry-level BSNs in 2013, but this was not sufficient to meet demand.
- With changes in access to healthcare, more Americans may soon require nursing services.

Aging Nurse Workforce

- According to a 2015 study conducted by the National Council of State Boards of Nursing (2015) and the Forum of State Nursing Workforce Centers, 50% of the RN workforce is age 50 or older. Furthermore, the U.S. Department of Health and Human Services, Health Resources and Services Administration (2014) predicts that in the next 10 to 15 years, more than 1 million RNs will reach retirement age and begin to withdraw from the workforce.
- New graduates are entering the workforce at an older age and will have fewer years to work.

Shortage of Nursing Faculty

- U.S. nursing schools turned away more than 79,659 qualified applicants in 2012 due to budget constraints and insufficient faculty and clinical sites.
- There is a 12% shortfall in the number of nurse educators needed.

Changing Demographics

- The number of individuals in the U.S. population age 65 and older is expected to double between 2000 and 2030.
- The ratio of potential caregivers to older adults will decrease by 40% between 2010 and 2030.

Increased Demand for Nurses

- Because of the increased acuity of hospital patients, demand for skilled and specialized nurses is rising.
- Shorter hospital stays mean that more nurses are needed to care for patients in long-term care and community settings.

Workplace Issues

- Inadequate wages and low nurse recruitment contribute to staffing shortages.
- Staffing shortages, including insufficient support staff, result in excessive workloads and greater reliance on overtime.
- Long hours and task overload cause high nurse turnover and vacancy rates, with many experienced nurses leaving the profession altogether.

areas are experiencing acute nursing shortages. Simply put, demand for nurses exceeds supply, especially in specialized areas such as critical care, and this situation is only expected to get worse (AACN, 2014).

Healthcare systems, policy makers, nursing educators, and professional organizations must work together to fix the nursing shortage problem. Some recommended actions for addressing this problem include the following:

- Giving nursing students the means to enter and progress through educational programs more rapidly and efficiently
- Stepping up efforts to recruit young people early in the course of their education (e.g., in middle and high school)
- Providing greater scheduling flexibility, better rewards for experienced nurses who serve as mentors, more adequate staffing, and increased salaries to improve nurses' work environment
- Increasing funding for nursing education

Case Study » Part 3

Lisa Rossi, the social worker, meets with Ms. Miller and learns that she is a single mother with a long history of back pain who appears dejected about the amount of time and effort she puts into being a mom. "I am not a person who gives in to things easily," Ms. Miller said. "That's why I think it is so unfair. Why me? There are so many things I should be able to do. And if I don't ignore my pain, it ruins so much in my life. I have been suffering through many snowboarding and camping trips with my children, but I don't want them to know that."

Ms. Rossi allows time for Ms. Miller to discuss her concerns and then briefly teaches her how to do slow yoga-type breathing to help her anxiety. After Ms. Miller practices the slower breathing, Ms. Rossi asks her whether she is ready to meet with the clinical pharmacist who will work with her to find the best options for pain management both while she is in the hospital and after discharge. Ms. Miller agrees to the plan.

The information from the social worker helps Dan Kramer, the clinical pharmacist, plan appropriate interventions for Ms. Miller. Dr. Kramer is able to meet with Ms. Miller that evening, and afterward he discusses the medication plan with Jen Sturges and Ms. Menendez. The next day, after a few doses of IV morphine and some oral narcotics, Ms. Miller is able to relax and take part in care activities. By the time the doctor discusses discharge plans with her, Ms. Miller describes how she had learned to recognize the pain not so much as an enemy, but rather as a signal to move or to calm down. She also learns that medication is not an enemy if it helps her with her daily life. In addition, she mentions that working with an occupational therapist has helped her understand how to calculate and plan all of her daily activities, physical and otherwise, to ensure her ability to participate in her usual social and occupational roles.

Clinical Reasoning Questions Level I

1. What role did technology play in the patient's care plan?
2. What information would you expect the social worker to share with Jen Sturges?

Clinical Reasoning Questions Level II

3. What role did the social worker take with Ms. Miller? How did the social worker's interview and discussion help with the patient's care and further activity?
4. Why was it important for the pharmacist to meet with the patient and then discuss the plans with Jen Sturges and Ms. Menendez?

REVIEW The Concept of Accountability

RELATE Link the Concepts

Linking the concept of accountability with the concept of legal issues:

1. What is the nurse's legal obligation to the patient related to accountability, and how is it regulated?
2. A nurse makes a medication error that results in harm to the patient. The nurse demonstrates accountability by immediately informing the physician and nursing supervisor when the error is recognized. How does the nurse's proper demonstration of accountability affect the nurse's legal responsibility?

Linking the concept of accountability with the concept of comfort:

3. What is the nurse's role in assessment and appropriate interventions to ensure comfort for the patient?
4. How does lack of patient comfort impede the patient's taking part in care plans and activities?

Linking the concept of accountability with the concept of ethics:

5. How does the nursing code of ethics reflect the expectation that the nurse is accountable when providing patient care?
6. A nurse believes that the physician has written orders that may endanger the patient. The nurse consults the physician, who refuses to alter the orders. What is the nurse's ethical obligation to the patient in order to demonstrate accountability?

Reflect Apply Your Knowledge

Frank Epworth is a 78-year-old man who presents to the emergency department complaining of nausea, vomiting, and severe pain in his left side and back, just below his ribs. Mr. Epworth states that these symptoms began suddenly. He also mentions that he is having difficulty passing urine; despite increased urge and several attempts to "go," he last urinated two hours ago, and at that time, he noted small amounts of blood in his urine. Based on these symptoms, the patient's reported medical history, and the physical examination, the physician suspects that Mr. Epworth has urolithiasis, or kidney stones. Imaging studies confirm the diagnosis. The physician has requested a urology consult. She has also ordered additional urinalysis and blood testing to learn more about Mr. Epworth's condition, but the results are still pending. In the meantime, you are the RN charged with Mr. Epworth's care.

As you review Mr. Epworth's chart, you note that the physician has authorized administration of Dilaudid 1–4 mg IV prn for pain management. The physician has also ordered you to push IV fluids at a rate of 500 mL/hour in hopes of helping Mr. Epworth pass the stone. Mr. Epworth's urine must also be collected, measured, and strained so that any stone fragments can be analyzed to determine their composition. After consulting the chart, you perform a brief nursing assessment during which Mr. Epworth rates his pain as 8 on a scale

of 0 to 10. Therefore, after starting IV fluids as ordered, you administer 1 mg of Dilaudid. You also task the LPN involved in Mr. Epworth's care with urine collection responsibilities and helping Mr. Epworth remain as comfortable as possible.

1. Half an hour later, you speak with the LPN. He notes that Mr. Epworth passed 30 mL of urine about 5 minutes ago, which he noted in the patient's chart. He also states that he disposed of the urine without straining it for stones. As the RN, are you accountable for the LPN's error? Why or why not?

2. An hour after the initial administration of Dilaudid, you reassess Mr. Epworth's pain level. He says that the medication didn't seem to provide any relief, so you administer another 3 mg of Dilaudid per the doctor's order. Will you be accountable if this additional dose fails to control Mr. Epworth's pain? Why or why not?
3. Shortly after starting Mr. Epworth's IV, you recall reading recent clinical guidance advising that large fluid pushes are rarely effective in facilitating stone passage. In this scenario, how might the standards of nursing accountability affect your subsequent course of action?

Exemplar 42.A Competence

Exemplar Learning Outcomes

42.A Analyze competence as it relates to accountability.

- Describe the areas of competence.
- Explain the importance of lifelong competence for nurses.

Overview

Competence is defined as possessing the knowledge and skills necessary to perform one's job appropriately and safely (Makely, 2012). In the past, nurses were considered able to do their job if they could simply provide care and comfort. Today, nurses are held to a higher standard of competence. Each nurse is expected to achieve and maintain competence within four main areas: health promotion, illness prevention, health restoration, and caring for the dying.

Areas of Competence

A variety of knowledge bases and professional skills are involved in the four major areas described below. Within each area, nurses are expected to achieve and demonstrate competence in the application of the nursing process, as well as in those skills necessary to provide safe and appropriate care.

Health and Wellness Promotion

According to the World Health Organization (WHO, 2017), health is a complete state of physical, mental, and social well-being and not just the absence of disease. Thus, **health promotion** can be defined as a process that enables individuals and communities to increase their control over the determinants of well-being, thereby improving their overall health (Dawson & Grill, 2012). Similarly, **wellness** can be described as a state of being in which individuals engage in activities and behaviors that enhance their quality of life and maximize their personal potential, including their physical fitness and emotional health (Lerner et al., 2013). Both patients who are healthy and patients who are ill may benefit from wellness-related nursing services. This process of health promotion may involve such things as improving nutrition and physical fitness, preventing drug and alcohol misuse, restricting

Exemplar Key Terms

Wellness, 2704

smoking, preventing accidents and injury in the home and workplace, and other health-enhancing activities at the individual, community, and workplace levels. Educating patients is an especially important element of health and wellness promotion. See the Module on Teaching and Learning for information on the nurse's role in providing patient teaching.

SAFETY ALERT When engaging in health and wellness promotion activities, nurses may encourage regular exercise, a key intervention that can significantly reduce the risk of many common conditions. Exercise comes with its own set of risks for injury, though, and some medical conditions require restricting physical activity, so the nurse should work with the patient to develop an appropriate exercise plan that aligns with the patient's specific needs.

Illness Prevention

Nurses engage in **illness prevention** in every setting in which they work. Illness prevention programs in community settings are designed to maintain optimal health by preventing disease. Some examples of community-level illness prevention include immunization programs, prenatal and infant care programs, and programs aimed at stopping the spread of sexually transmitted infections. These programs are frequently facilitated by nurses working in school settings, hospital outreach programs, and local health departments.

Within clinical settings, nurses engage in illness prevention in a variety of ways, such as by observing equipment sterilization precautions and engaging in patient teaching. These and other methods of illness prevention are discussed throughout Parts I, II, and III of this text.

Health Restoration

Ill patients are the focus of **health restoration**, which extends from early detection of disease through the process

of helping patients during the recovery period. Critical nursing competencies in the area of health restoration include providing direct care; conducting assessments; patient teaching about recovery activities; and assisting patients with achieving optimal functional level of physical, cognitive, psychologic, and spiritual health.

Caring for the Dying

Caring for the dying involves helping terminally ill patients of all ages live as comfortably as possible until death, as well as helping these patients' support individuals cope with death. Nurses care for the dying in a variety of settings, including homes, hospitals, and extended care facilities. The End-of-Life Care exemplar in the module on Comfort provides more information on caring for the dying.

Promoting Lifelong Competence

Nurses gain competence gradually throughout nursing school until they reach a level at which they are judged safe and skillful enough to function as newly graduated nurses. Nurses continue to build competence throughout their career, with expertise coming from experience, gaining new knowledge, and improving their performance of skills.

Maintaining and increasing competence in nursing require the nurse to continue learning. Professional development and continuing education opportunities come in a variety of forms, including seminars offered by colleges and professional organizations, professional and peer-reviewed journals, hospital- or employer-sponsored classes on new equipment or procedures, and formal and informal discussions with peers and other members of the healthcare team. All nurses must assess their own level of knowledge and identify areas in which they need additional knowledge in order to provide appropriate patient care.

Even the most competent nurses sometimes encounter situations that make them question how best to respond. Luckily, nurses can collaborate with each other and with others on the interprofessional team, sharing opinions, ideas, and information. Although collaboration is helpful and even critical, each nurse is nevertheless accountable for his or her own choices and must weigh all information and choose the best course of action. The nurse who recognizes that there will always be a need to collaborate with others maintains a safe practice.

Various models have been developed in an attempt to explain the process by which nurses attain competence. One classic model is that developed by Benner (2001), which describes five levels of proficiency in nursing: novice, advanced beginner, competent, proficient, and expert (**Box 42-3** >>). Benner's model proposes that experience is essential for the development of professional expertise—and this idea has significant implications for teaching and learning.

SAFETY ALERT As nurses pass through Benner's stages of nursing expertise, they gain not only knowledge and fluency, but also a more intuitive sense of patient safety. By the expert level, medication

Box 42-3

Benner's Stages of Nursing Expertise

Stage I: Novice

No experience (e.g., a nursing student). Performance is limited, inflexible, and governed by context-free rules and regulations rather than experience.

Stage II: Advanced Beginner

Demonstrates marginally acceptable performance.

Recognizes the meaningful aspects of a real situation. Has experienced enough real situations to make judgments about them.

Stage III: Competent

Has 2 or 3 years of experience. Demonstrates organizational and planning abilities. Differentiates important factors from less important aspects of care. Coordinates multiple complex care demands.

Stage IV: Proficient

Has 3 to 5 years of experience. Perceives situations as wholes rather than in terms of parts as in Stage II. Uses maxims as guides for what to consider in a situation. Has holistic understanding of the client, which improves decision making. Focuses on long-term goals.

Stage V: Expert

Performance is fluid, flexible, and highly proficient; no longer requires rules, guidelines, or maxims to connect an understanding of the situation to appropriate action. Demonstrates highly skilled intuitive and analytic ability in new situations. Is inclined to take a certain action because "it felt right."

Source: Benner, P. (2001). *From novice to expert: Excellence and power in clinical nursing practice, commemorative edition* (1st ed.). Upper Saddle River, NJ: Pearson Education. Reprinted and electronically reproduced by permission of Pearson Education, Inc., New York, NY.

doses and sterilization procedures that once required careful training and memorization become easy to perform. Even at the expert level, however, nurses must double-check their actions to ensure that patients' safety needs are always being met.

Regardless of their exact level of proficiency, all nurses must hold themselves accountable by frequently weighing and assessing their own competence. This includes competence not just in applying nursing knowledge and carrying out clinical skills, but also in recognizing and dealing with various cultural issues that may arise. (See the Focus on Diversity and Culture feature for more information.) Furthermore, in all situations, nurses should understand that it is more honorable to say "I don't know" or ask "Would you help me?" than to say "I'm not sure but I think this is right" or "I'll figure it out as I go along." In fact, the first rule of competence in providing patient care is to ask for help whenever there is uncertainty about the safety of any given action. By doing so, nurses both invite opportunities to increase their own level of competence and hold themselves accountable for providing the highest quality of patient care.

Focus on Diversity and Culture

Teaching Cultural Competence

Adequate healthcare is a universal human right, so it is essential that nurses gain the skills necessary to communicate cross-culturally in this era of increasing diversity. According to Jeffreys (2015), “culturally congruent” healthcare refers to healthcare that is customized to fit with the patient’s cultural values. Nurses must learn to practice culturally congruent healthcare by actively seeking to expand their level of cultural competence. This means embracing a “broader, more inclusive worldview that appreciates various forms of diversity and [considers] various philosophies and approaches to learning” (Jeffreys, 2015). Healthcare organizations and schools of nursing must also seek to provide current and future nurses with cultural competence training. But what, exactly, should this sort of teaching entail?

Many researchers have considered this question, with varying results. Still, several broad recommendations have emerged. For instance, Raman (2015) highlights multiple studies suggesting that cultural competence training is most effective when delivered by a diverse team of nurse educators who have engaged in thorough self-assessment of their own cultural knowledge and

limitations. Raman also recommends that these educators have significant experience working among individuals who are “ethnically and culturally different from themselves.” Similarly, Truong, Paradies, and Priest (2014) point out several studies recommending that healthcare organizations evaluate their own strengths and weaknesses, along with the unique needs of their patients, prior to developing in-house cultural competence training programs. Evidence from several studies also indicates that such programs are most effective when they “connect cultural competency to professional values rather than legal or organizational requirements, fostering a safe and respectful learning environment, cultivating cultural humility, and avoiding stereotypes throughout the training” (University of Wisconsin Population Health Institute, 2015). This last point is echoed by George, Thornicroft, and Dogra (2015), who emphasize the value of cultural competence training programs that are driven by clinical need rather than political concerns and that avoid assuming that all members of a particular cultural group are homogeneous in terms of their beliefs and practices.

REVIEW Competence

RELATE Link the Concepts and Exemplars

Linking the exemplar on competence with the concept of legal issues:

1. What is the nurse’s legal obligation to society and the profession to maintain competence?
2. How can nurses who lack competence in one area of nursing strengthen their knowledge and skills?

Linking the exemplar on competence with the concept of ethics:

3. What is the nurse’s ethical obligation related to competence?
4. How does the nursing code of ethics address the issue of competence?

REFLECT Apply Your Knowledge

Tyree Campbell has worked in the labor and delivery unit of a large metropolitan hospital since graduating from nursing school 8 years ago. A new private hospital recently opened in town, and the census on Ms. Campbell’s unit has been significantly lower. Tonight, Ms. Campbell reports to work and learns that more nurses are scheduled to work than there are patients. The decision has been made to float the excess staff to other units, and Ms. Campbell is asked to float to the neonatal intensive care unit (NICU). Her heart sinks, and she begins to feel the early signs of panic as she thinks, “How can I work in the NICU? I don’t have any experience working there!”

1. What is Ms. Campbell’s responsibility in this situation?
2. Can Ms. Campbell agree to float to the NICU if she is not competent to care for the patients on this unit? Explain your answer.
3. What should Ms. Campbell say to the nursing supervisor who has given her this assignment?

Exemplar 42.B

Professional Development

Exemplar Learning Outcomes

42.B Analyze professional development as it relates to accountability.

- Analyze the history of nursing.
- Explain the effects of women’s status, religion, war, and societal attitudes on nursing.
- List nursing leaders who made notable contributions to the profession.
- Differentiate the components of contemporary nursing practice.
- Differentiate expanded careers for nurses.

Exemplar Key Terms

Line authority, 2710
Organizational chart, 2711
Responsibility, 2710
Staff authority, 2710
Standards of Practice, 2710
Standards of Professional Performance, 2710

Overview

Professional development takes on different meanings in the many different areas of nursing. The term may be associated with advanced education, an increase in experience or seniority, involvement or membership in an organization that governs the profession, or continuing education classes or offerings. Professional development encompasses all of these activities.

Nursing today is very different from nursing as it was practiced years ago, and it is expected to continue changing. To understand nursing in the present as well as prepare for the future, nursing students must understand not only past events but also contemporary nursing practice and its sociologic and historical influences.

Historical Perspectives

Over the centuries, societal needs and influences have brought about dramatic changes in nursing. From its beginnings, nursing has struggled for autonomy and professionalization—a struggle that continues in the present. A renewed interest in nursing history has in recent decades produced a growing body of literature on the subject. The following sections touch on only selected aspects of influential events in nursing practice. Themes that recur throughout this history of nursing include issues related to women's roles and status, religious values, war, societal attitudes, and visionary nursing leadership. Many of these factors continue to influence nursing in the present.

Women's Roles and Status

The female roles of wife, mother, daughter, and sister have traditionally included the care and nurturing of others. Women have cared for infants and children from the beginning of time, and nursing could legitimately be said to have its roots in "the home." Additionally, women, who in general occupied a subservient and dependent role, were frequently called on to care for others in the community who were ill. Most often, this care involved the promotion of physical maintenance and comfort. Humanistic caring, nurturing, comforting, and supporting have thus always been components of the traditional nursing role.

Religion

Religion has also played a significant role in the development of nursing. Although many of the world's religions emphasize benevolence, Western nursing in particular has been influenced by the Judeo-Christian commandment to "love thy neighbor as thyself" and Christ's parable of the Good Samaritan. Throughout its history, nursing has also drawn on other religious values such as self-denial, devotion to duty and hard work, and the idea of a spiritual calling. In the early history of nursing, religious organizations supported or provided nursing care. Examples include the Daughters of Charity of Vincent de Paul in France, who provided psychiatric nursing care as early as the 17th century. Deaconess groups also provided nursing care, most notably when Theodore Fliedner reinstituted the Order of Deaconesses in Kaiserswerth, Germany, in 1836 and opened a small hospital and training school there. This school is where Florence Nightingale received her training in nursing.

Religion continues to influence nursing, albeit in different ways. Most notably, today's nurses are increasingly seeking ways to honor patients' religious beliefs in their practice (Sayles, 2016).

War

Throughout history, wars have demanded nurses to care for the wounded. Several orders of knights—including the Knights of Saint John of Jerusalem (also known as the Knights Hospitalers), the Teutonic Knights, and the Knights of Saint Lazarus—were formed during the Crusades to provide nursing care to their sick and injured comrades. Eventually, these groups began to provide care to others as well. For example, because the group's original members were themselves lepers, the Knights of Saint Lazarus chose to dedicate themselves to the care of individuals with leprosy, syphilis, and chronic skin conditions. These orders also built hospitals, the organization and management of which set a standard for hospital administration throughout Europe at that time.

Centuries later, the inadequacy of the care given to soldiers during the Crimean War (1854–1856) led to a public outcry in Great Britain. Florence Nightingale played a well-known role in addressing this problem when Sir Sidney Herbert of the British War Department asked her to recruit a contingent of female nurses to care for the sick and injured in the Crimea. Nightingale and her nurses set up practices that transformed sanitation standards for military hospitals, such as hand washing and laundering clothing. Through efforts like these, Nightingale and her nurses helped decrease the mortality rate in the Barrack Hospital in Turkey from 42% to a remarkable 2% (Donahue, 1996, p. 197).

Shortly after Nightingale's work in the Crimea, several Americans made notable contributions during the U.S. Civil War (1861–1865). Although not technically nurses, Harriet Tubman and Sojourner Truth provided care and safety to slaves fleeing to the North on the Underground Railroad. Meanwhile on the battlefields, Mother Biekerdyke and Clara Barton provided care to injured and dying soldiers. Dorothea Dix became the Union Army's superintendent of female nurses. In this role, she was responsible for recruiting nurses and supervising the care provided by all women nurses working in army hospitals during the Civil War.

American, British, and French women all rushed to volunteer their nursing services when World War I broke out in the 1910s. These nurses had to endure harsh environments and treat unprecedented injuries. World War I also brought progress in other areas of healthcare, particularly in the surgical field. Other examples of war-related advances included more effective use of anesthetic agents, infection control, blood typing, and prosthetics.

Approximately 90% of the 11,000 American military women stationed in Southeast Asia during the Vietnam War were nurses. Most of these women volunteered to go to Vietnam immediately following graduation from nursing school, making them the youngest group of medical personnel ever to serve in wartime (Vietnam Women's Memorial Foundation, n.d.).

Today, U.S. military nurses serve individuals and populations worldwide during times of war and peace. For example,

Army nurses responded to and helped to develop protocols for the Ebola crisis in Africa and the United States. Their work continues to influence the health and safety of active service men and women, the nation's veterans, and civilians at home and abroad (Military Health System Communications Office, 2015).

Societal Attitudes

Over the years, professional nursing has been significantly influenced by societal attitudes concerning nurses and nursing. For example, nurses lacked organization, education, or social status prior to the mid-1800s because of the pervasive attitude that a woman's place was in the home. During this time, it was not respectable for women to pursue careers. Most hospital-based nurses of the era were poorly educated, and some were even incarcerated criminals. Charles Dickens' novel *Martin Chuzzlewit* (1896) reflected society's attitudes about nursing during this period; in that book, Sairey Gamp's "care" for the sick included neglect, theft, and physical abuse (Donahue, 1996, p. 192). This character's portrayal did much to influence the negative image of nurses.

In the latter part of the nineteenth century, thanks largely to Florence Nightingale's efforts during the Crimean War, a contrasting image of the nurse as *guardian angel* or *angel of mercy* arose in the popular imagination. Nightingale brought new respectability to the nursing profession, changing the image of nurses from cruel and exploitive to noble, compassionate, moral, religious, dedicated, and self-sacrificing.

As the nursing profession developed during the twentieth century, so did the efforts of nurses to take more active steps to improve the image of nursing. For example, during the early 1990s, the Tri-Council for Nursing (which consists of the American Association of Colleges of Nursing, the ANA, the American Organization of Nurse Executives, and the NLN) initiated a national effort titled *Nurses of America*, which focused on elevating nursing's professional image. In 2002, the Johnson & Johnson corporation launched the Campaign for Nursing's Future, which promoted nursing as a positive career choice and a trusted profession. In 2010, the Institute of Medicine (IOM) and the Robert Wood Johnson Foundation (RWJF) launched the Initiative on the Future of Nursing, which focused on identifying solutions of nursing care that not only addressed many of the issues facing the profession, but also transformed the way Americans receive healthcare. This initiative was based on the belief that nurses are a linchpin for health reform and will be vital in implementing systemic changes in the delivery of care (IOM, 2010).

Nursing Leaders

Leaders such as Florence Nightingale, Clara Barton, Lillian Wald, Lavinia Dock, Margaret Sanger, and Mary Breckinridge made notable contributions to both nursing's history and women's history, and their skills at influencing others and bringing about change make them potent models for political nurse activists today. Contemporary nursing leaders have also played important roles in the profession. For example, Virginia Henderson created a modern worldwide definition of nursing, and Martha Rogers made important theoretical contributions.

Florence Nightingale (1820–1910)

Florence Nightingale's contributions to nursing are well documented. During the Crimean War, she made such great strides in improving standards of care for war casualties that her efforts earned her the title "Lady with the Lamp." She also became an accomplished political nurse—the first nurse, in fact, to exert political pressure on government—in her zeal to reform hospitals and produce and implement public health policies. Her greatest achievements, however, were her contributions to nursing education and her pioneering work *Notes on Nursing: What It Is, and What It Is Not* (1859/1969), which established Nightingale as nursing's first scientist-theorist.

Clara Barton (1812–1912)

A schoolteacher who volunteered as a nurse during the American Civil War, Clara Barton was given the responsibility of organizing the nursing services. She established the American Red Cross and in 1882 persuaded Congress to ratify the Treaty of Geneva (the first Geneva Convention), which linked the American Red Cross with the International Red Cross to perform humanitarian efforts in times of peace.

Linda Richards (1841–1930)

Linda Richards graduated from the New England Hospital for Women and Children in 1873, thereby becoming America's first trained nurse. Richards did pioneering work in psychiatric and industrial nursing, and the practices of nurse's notes, doctor's orders, and nurses wearing uniforms all originated with her (ANA, 2016a).

Mary Mahoney (1845–1926)

In 1879, Mary Mahoney graduated from the New England Hospital for Women and Children to become the first African American professional nurse. Mahoney promoted equal opportunities and worked constantly for African Americans to be accepted in nursing (Donahue, 1996, p. 271). The ANA (2016b) gives the Mary Mahoney Award biennially to recognize significant contributions, whether by individual nurses or groups of nurses, to the advancement of racial integration in nursing.

Lillian Wald (1867–1940)

Lillian Wald is considered the founder of public health nursing. Wald and Mary Brewster were the first to offer trained nursing services to the poor in the New York slums. They provided nursing and social services as well as organized educational and cultural activities. Wald pushed for school nursing as an adjunct to visiting nursing soon after founding the Henry Street Settlement.

Lavinia Dock (1858–1956)

A friend of Lillian Wald and a feminist, prolific writer, political activist, and suffragist, Lavinia L. Dock campaigned both for the passage of the 19th Amendment securing women's right to vote, but also for legislation to make the profession of nursing autonomous by allowing nurses, not physicians, to control it. Dock, assisted by Mary Adelaide Nutting and Isabel Hampton Robb, founded the American Society of Superintendents of Training Schools for Nurses of the

United States and Canada in 1893; this was a precursor to the current National League for Nursing.

Margaret Sanger (1879–1966)

A public health nurse in New York, Margaret Higgins Sanger had a lasting impact on women's healthcare and reproductive rights. She was imprisoned for opening America's first birth control information clinic and is considered the founder of Planned Parenthood. Sanger brought attention to the large number of unwanted pregnancies among the working poor and pushed for this issue to be addressed.

Mary Breckinridge (1881–1965)

In 1918, immediately following the end of World War I, Mary Breckinridge worked with the American Committee for Devastated France to distribute food, clothing, and supplies to rural villages and care for sick children. After returning to the United States in 1921, Breckinridge acted on her plans to provide healthcare to the people of rural America, establishing the Frontier Nursing Service (FNS) in 1925 with two other nurses in Leslie County, Kentucky. Within the FNS, Breckinridge started one of the first midwifery training schools in the United States.

Contemporary Nursing Practice

Examining the definitions of nursing, who receives nursing services, the settings for nursing practice, nurse practice acts, and current standards for clinical nursing can help cultivate a deeper understanding of contemporary nursing practice.

Definitions of Nursing

Almost 150 years ago, Florence Nightingale defined nursing as “the act of utilizing the environment of the patient to assist him in his recovery” (Nightingale, 1859/1969). She considered a clean, well-ventilated, and quiet environment to be essential for patient recovery. Nightingale raised the status of nursing through education and is often considered the first nurse theorist. Thanks to her efforts, nurses were no longer untrained housekeepers but professional individuals formally educated in the care of the sick.

Virginia Henderson was one of the first modern nurses to define nursing. In her words, “The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will, or knowledge, and to do this in such a way as to help him gain independence as rapidly as possible” (Henderson, 1966, p. 3). Henderson described nursing in relation to the patient and the patient's environment, just as Nightingale did, but unlike Nightingale, Henderson saw the nurse as concerned with both healthy and ill individuals. She acknowledged that nurses interact with patients even when it might not be possible for them to recover and promoted the role of the nurse as both teacher and advocate.

In 1952, Hildegard Peplau published her landmark *Interpersonal Relations in Nursing*, which described and emphasized the importance of the nurse–patient relationship as a therapeutic process. Her pioneering work on nurse–patient

relations and on anxiety led to her being widely considered as the founder of modern psychiatric nursing.

In the latter half of the 1900s, a number of nurse theorists developed definitions of nursing. These theoretical definitions are important because they go beyond simplistic common definitions to describe not only what nursing is, but also the interrelationship among nurses, nursing, the patient, the environment, and the intended patient outcome. Certain themes are common to many of these definitions; for example, most theoretical definitions view nursing as:

- Caring
- An art
- A science
- Patient centered
- Holistic
- Adaptive
- Concerned with health promotion, health maintenance, and health restoration
- A helping profession

Professional nursing associations have also scrutinized the nursing profession and contributed their own definitions of nursing. In 1973, the ANA described nursing practice as “direct, goal oriented, and adaptable to the needs of the individual, the family, and community during health and illness” (p. 2), but the organization changed its definition of nursing in 1980 to this: “Nursing is the diagnosis and treatment of human responses to actual or potential health problems” (p. 9). Later, in 1995, the ANA recognized the contribution that the science of caring had made to nursing philosophy and practice. Its current definition of professional nursing is therefore much broader than earlier definitions: “Nursing is the protection, promotion, and optimization of health and abilities, preventions of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations” (ANA, 2003, p. 6).

Settings for Nursing

The many and varied settings for nursing practice include acute care hospitals, community agencies, ambulatory clinics, long-term care facilities, health maintenance organizations (HMOs), nursing practice centers, and patients' homes (see **Figure 42-1** »).

Depending on the setting, nurses may have different degrees of autonomy and responsibility. They may provide direct care, or they may teach patients and support individuals. They may also serve as advocates and agents of change, helping determine the health policies that affect consumers in hospitals and in the community.

Nurse Practice Acts

Nurse practice acts are legal acts that regulate the practice of nursing in the United States and Canada. Each state in the United States and each province in Canada has its own nurse practice act. Although their content differs from jurisdiction to jurisdiction, the common purpose of all nurse practice acts is to protect the public. Nurses are responsible for knowing how their state's nurse practice act governs

Figure 42-1 » Nurses practice in a variety of settings. Clockwise from left: pediatric nursing, operating room nurse, geriatric nursing, home nursing, and community nursing.

their practice. The module on Legal Issues discusses nurse practice acts in detail.

Standards of Nursing Practice

A professional organization's major functions include establishing and implementing standards of practice. The ANA's **Standards of Practice**, for example, are intended to describe the responsibilities for which American nurses are accountable. The ANA uses the nursing process as a foundation to develop generic standards of nursing practice that apply regardless of area of specialization. Similarly, the ANA uses its **Standards of Professional Performance** to describe the expected behavior of professional nurses. Professional performance standards refer to enhancing general practice, ensuring appropriate education level, and maintaining collegiality with peers and collaboration with the entire care team. Because of the increasing use of the internet and social networking sites such as Facebook and Twitter, in 2011 the ANA published principles for social networking in nursing. In addition to the ANA, specialty nursing organizations have developed standards of nursing practice specific to their areas of specialization. Each province or territory in Canada also establishes its own standards of practice for nurses.

Competent nurses use the nursing process—that is, the steps of assessment, diagnosis, planning, implementation, and, ultimately, evaluation—in their nursing practice. A

professional nurse also integrates ethics in all areas of practice and considers appropriate use of resources while functioning in relevant leadership roles (ANA, 2015).

Chain of Command

The **chain of command** is the hierarchy within an organization. The authority and responsibility of the individuals in the organization depend on their position in the chain of command. **Authority** is the power to command other individuals and direct their activities; **responsibility** is being accountable for meeting personal or organizational objectives and performing required tasks.

Line authority is the power to direct the activities of subordinates within the organization. In **Figure 42-2** », examples of line authority include the relationships among the chief nurse executive, the nurse manager, and the staff nurse. **Staff authority** is the power to provide advice and support to employees or departments but not to assign tasks. In **Figure 42-2**, staff authority is illustrated by the relationship between the acute care nurse practitioner and the nurse manager. Neither is responsible for the work of the other; rather, they collaborate to optimize care in the unit for which the nurse manager is responsible.

A chain of command provides structure, so employees understand how to perform their tasks and how to manage supervisory relationships within the organization. It also

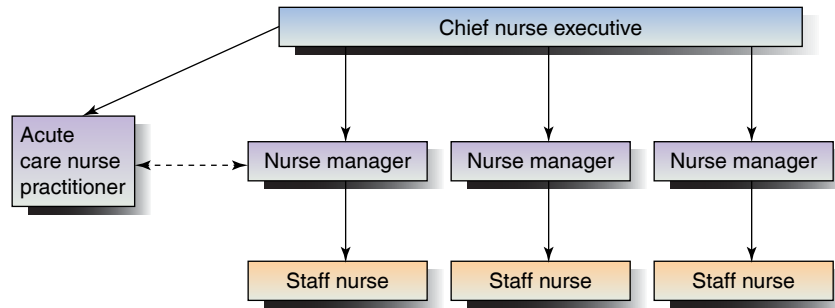

Figure 42-2 » Organizational chart showing chain of command in a nursing unit.

provides a structure for reporting issues that need management's attention. Any nurse who identifies such an issue should follow the organization's chain of command. For example, in a hospital, a problem is usually first reported to the charge nurse, then to the unit manager. If the problem is still not resolved, the nurse may approach someone in middle or upper management.

The student nurse should always follow the chain of command, and the nursing instructor acts as the first link in that chain. When a problem arises, whether in the clinical area or the classroom, the student should first discuss the problem with the instructor. If the instructor is unable to resolve the issue to the student's satisfaction, the student should then approach the program director. Failure to follow the chain of command is considered unprofessional and slows the resolution process. In some organizations, failure to follow the chain of command may result in disciplinary action.

In traditional organizations, an **organizational chart** depicts the formal hierarchical structure and related responsibilities of the individuals or positions that are depicted on the chart. However, organizations also have informal structures that are not reflected in a chart. For instance, nurses who function as leaders but do not have a formal title in the hierarchy would not appear in the organizational chart. Similarly, managers who have strong personalities or other characteristics may have more actual power than other managers with the same formal level of authority, but these differences are not shown in the chart.

The traditional hierarchical structure is not the only model used in healthcare settings. Many organizations have moved toward a shared governance model that flattens the organizational chart as appropriate participants (such as nursing staff, pharmacy staff, and medical staff) share ownership of patient care issues and outcomes (Charland, 2015).

Roles and Functions of the Nurse

When they provide patients with care, nurses perform a number of roles, often simultaneously. The nurse, for example, may not only provide physical care, but also act as a counselor to teach the patient aspects of that care. The needs of the patient and the aspects of the patient's environment at a particular time determine which roles a nurse will be required to fulfill. These roles, briefly outlined in **Table 42-1** », are discussed throughout this text.

As the nursing profession has grown in autonomy through professional organizations, nursing leaders and managers have seen a need for a number of expanded roles in the nursing profession. Some of these roles, such as that of the nurse-midwife, have come about partly as a response to needs expressed by patients. Others, such as that of the nurse educator, have resulted primarily from the profession's desire to continue to improve, educate, and renew its own members.

Expanded Career Roles for Nurses

Expanded career roles that allow greater independence and autonomy are available to many nurses. Such roles include nurse practitioner, clinical nurse specialist, nurse-midwife, nurse educator, and nurse anesthetist. Although exact requirements for these roles are defined in each state's nurse practice act, they almost universally reflect the standards below.

Nurse Practitioner

The basic requirements for becoming a nurse practitioner are advanced education (master's degree or higher), graduation from a nurse practitioner program, and American Nurses Credentialing Center (ANCC) certification in a particular area. These areas include adult nurse practitioner, family nurse practitioner, school nurse practitioner, pediatric nurse practitioner, and gerontology nurse practitioner. Nurse practitioners must hold both an RN license and a nurse practitioner license in order to practice. Nurse practitioners usually provide primary ambulatory care as well as care for patients with nonemergency acute or chronic illness, and they are employed in healthcare agencies or in community-based settings.

Clinical Nurse Specialist

A clinical nurse specialist is a nurse who possesses an advanced degree (master's or higher) with emphasis on a specialized area of practice, such as gerontology or oncology. To become a clinical nurse specialist, the nurse must hold RN licensure and pass a certification exam administered by the ANCC. Most states then require the nurse to obtain separate licensure as a clinical nurse specialist. Depending on their specialty and job setting, clinical nurse specialists provide direct patient care, educate others, consult, conduct research, and manage care.

TABLE 42–1 Roles and Functions of the Nurse

Nursing Role	Functions
Caregiver	The nurse engages in activities that assist the patient physically and psychologically while preserving the patient's dignity.
Communicator	The nurse identifies patient problems and communicates these to other members of the healthcare team. (See the module on Communication.)
Teacher	Nurses help patients learn about their health and about healthcare procedures used to restore or maintain their health. Nurses also teach unlicensed assistive personnel (UAP) to whom they delegate care, and they share their expertise with other nurses and healthcare professionals. (See the module on Teaching and Learning.)
Patient advocate	The nurse may represent the patient's needs and wishes to other health professionals, such as relaying the patient's wishes for information to the physician. The nurse also assists patients in exercising their rights and helps them speak up for themselves.
Counselor	Nurses counsel healthy individuals with normal adjustment difficulties and focus on helping these individuals develop new attitudes, feelings, and behaviors by encouraging them to look at alternative behaviors, recognize the choices, and develop a sense of control. Nurses counsel ill patients in how to develop more healthy and self-protective behaviors and how to recognize and respond to triggers, signs, and symptoms in a timely manner.
Change agent	Nurses assist patients to make modifications in their behavior. Nurses also often act to make changes in a system, such as clinical care, if it is not helping a patient return to health. Nurses are continually dealing with changes in the healthcare system. Technologic changes, changes in the age of the patient population, and changes in medications are just a few that nurses deal with daily.
Leader	A leader influences others to work together to accomplish a specific goal. The leader role can be employed at different levels: individual patient, family, groups of patients, colleagues, or the community. Effective leadership is a learned skill requiring an understanding of the needs and goals that motivate individuals, the knowledge to apply the leadership skills, and the interpersonal skills to influence others. (Leadership is discussed further in the module on Professional Behaviors.)
Manager	The nurse manages the nursing care of individuals, families, and communities. The nurse manager also delegates nursing activities to ancillary workers and other nurses, as well as supervises and evaluates their performance. Managing requires knowledge about organizational structure and dynamics, authority and accountability, leadership, change theory, advocacy, delegation, and supervision and evaluation. (See the module on Collaboration for more information.)
Case manager	Nurse case managers work with the multidisciplinary healthcare team to measure the effectiveness of the case management plan and to monitor outcomes. Each agency or unit specifies the role of the nurse case manager. In some institutions, the case manager works with primary or staff nurses to oversee the care of a specific caseload. In other agencies, the case manager is the primary nurse or provides some level of direct care to the patient and family. Insurance companies have also developed a number of roles for nurse case managers, and responsibilities may vary from managing acute hospitalizations to managing high-cost patients or case types. Regardless of the setting, case managers help ensure that care is oriented to the patient while also controlling costs. (See the module on Managing Care for more information.)
Research consumer	Nurses often use research to improve patient care. In a clinical area, nurses need to (a) have some awareness of the process and language of research, (b) be sensitive to issues related to protecting the rights of human subjects, (c) participate in the identification of significant researchable problems, and (d) be a discriminating consumer of research findings.

Nurse Anesthetist

Nurse anesthetists administer general anesthetics for surgery under the supervision of a physician prepared in anesthesiology, as well as carry out preoperative and postoperative patient assessments. A nurse may qualify to be a nurse anesthetist after completing advanced education (master's degree or higher) in an accredited program in anesthesiology. Nurses who obtain this degree and already hold RN licensure may then sit for a certification examination offered by the National Board on Certification and Recertification of Nurse Anesthetists (NBCRNA). Nurses who pass this exam earn the title of Certified Registered Nurse Anesthetist (CRNA). Maintenance of the CRNA credential requires nurses to meet certain continuing education requirements set by the NBCRNA. Some states also require that CRNAs obtain separate licensure beyond that of a registered nurse.

Nurse-Midwife

Nurse-midwives provide prenatal and postnatal care and manage deliveries in normal pregnancies. They practice in association with a healthcare agency, which enables them to quickly obtain medical services should complications occur. Nurse-midwives may also conduct routine Papanicolaou tests, family planning counseling, and routine breast examinations. To become a nurse-midwife, a registered nurse must

complete an accredited graduate program in midwifery, earning a master's degree or higher. The nurse must then pass a certification exam offered by the American College of Nurse-Midwives. In many states, specialized licensure is also required.

Nurse Researcher

The role of the nurse researcher is to investigate problems in nursing and to discover solutions that may improve nursing care and refine and expand nursing knowledge. Academic institutions, teaching hospitals, and research centers, such as the National Institute for Nursing Research in Bethesda, Maryland, all employ nurse researchers. Nurse researchers typically have advanced education at the doctoral level.

Nurse Administrator

A nurse administrator manages patient care, including delivery of nursing services. He or she may have a middle management position, such as head nurse or supervisor, or a more senior management position, such as director of nursing services. The nurse administrator's functions include budgeting, staffing, and planning programs. To prepare for their role, nurse administrators complete at least a baccalaureate degree in nursing and frequently a master's or doctoral degree as well.

Nurse Educator

The nurse educator usually has a baccalaureate degree or more advanced preparation and frequently has expertise in a particular area of practice. Nurse educators work in nursing programs, at educational institutions, or in hospital staff education programs. They are responsible for classroom, skills laboratory, and often clinical teaching.

Nurse Entrepreneur

A nurse entrepreneur is someone who manages a health-related business and typically has an advanced degree. The nurse entrepreneur's business may involve education, consultation, or research.

Clinical Nurse Leader

The American Association of Colleges of Nursing (AACN) developed the role of clinical nurse leader to address the challenges of providing high-quality healthcare in the current environment (Wilson et al., 2013). Quality improvement and use of evidence-based solutions are hallmarks of this role. Clinical nurse leaders must hold a master's degree and have completed specialized coursework in areas such as pathophysiology, clinical assessment, finance management, epidemiology, and pharmacology. They must also pass a certification examination offered by the Commission on Nurse Certification.

REVIEW Professional Development

RELATE Link the Concepts and Exemplars

Linking the exemplar on professional development with the concept of legal issues:

1. What role does the nurse's continued professional development play in meeting the legal requirements for the profession?
2. What nursing regulations require continued professional development?

Linking the exemplar on professional development with the concept of ethics:

3. Can the nurse meet the ethical responsibilities of the profession without belonging to a professional organization? Explain.
4. How does the nursing code of ethics address the issue of professional development?

- Additional review materials

REFLECT Apply Your Knowledge

Francois Guardiène graduated from nursing school 4 years ago and accepted a position working in the coronary care unit (CCU) of a large metropolitan hospital. He was required to attend 6 weeks of hospital orientation and a 3-month class for CCU nurses. He worked under the supervision of a preceptor for an additional 3 months. During his first year of practice, Francois checked with more experienced nurses frequently, but with time, he began to have more confidence in his competence and established a more autonomous practice. Over the past 2 years, he has noticed that some individuals seek to collaborate with him, and he considers himself a good CCU nurse.

1. Has Mr. Guardiène satisfied the need for professional development? Explain your answer.
2. What obligations does Mr. Guardiène have to continue developing his professional practice?
3. How would a nurse's hospital orientation differ if the position involved an area less specialized than the CCU?

Module 43

Advocacy

Module Outline and Learning Outcomes

The Concept of Advocacy

The Advocate's Role

43.1 Analyze the role of the advocate in the practice of nursing.

Advocacy Interventions

43.2 Summarize advocacy interventions used by nurses.

Concepts Related to Advocacy

43.3 Outline the relationship between advocacy and other concepts.

Unethical or Unsafe Practice or Unprofessional Conduct

43.4 Describe the nurse's role in reporting unprofessional activities.

Advocacy Exemplar

Exemplar 43.A Environmental Quality

43.A Analyze the health indicator of environmental quality as it relates to advocacy.

>> The Concept of Advocacy

Concept Key Terms

Advocacy, 2715

Patient advocacy, 2715

Advocacy is a concept integral to both the American Nurses Association Code of Ethics for Nurses with Interpretive Statements (see the module on Ethics) and the International Council of Nurses' Code of Ethics for Nurses. **Advocacy** is generally defined as the act or process of supporting, defending, or assisting in another's cause. **Patient advocacy** can be defined as a process or strategy for acting on behalf of others (including patients, families, groups, or communities) to help them obtain services and rights that they might not otherwise receive but that they need to advance their well-being (Hanks, 2013; Jansson et al., 2014). Patient advocacy is a primary nursing role. The nurse may demonstrate advocacy by communicating the patient's needs to other health professionals; by facilitating, clarifying, or mediating communication between the patient and the primary care provider (PCP); or by assisting patients to exercise their right to receive care that is consistent with their circumstances, values, beliefs, and preferences. Successful advocacy results in positive outcomes for patients. It also provides nurses with a sense of professional satisfaction, having met a duty to provide individualized, culturally sensitive, patient-centered care.

Nurses are ethically obligated to act as advocates for all patients, but particularly for those who cannot advocate for themselves. Advocacy can occur at any level, in any setting,

from the bedside to the healthcare provider's office, from advocating for the individual patient to advocating for an entire population through advocacy for changes in public policies and services.

Successful advocacy requires a balanced approach. It may not be possible to act on every patient request. Skilled nurse-advocates are able to explain the rationale for care limitations to the patient in plain language and also manage their own ability to cope with disappointing outcomes to prevent frustration and burnout.

Learning the patient advocate role begins during the nursing education experience. With time, the nurse will gain proficiency in this role and incorporate advocacy activities into daily professional practice.

The Advocate's Role

Navigating the healthcare system is a challenge for any patient. Advances in healthcare knowledge, technology, and system complexity have progressed exponentially in the 21st century. The result is that patients are rapidly moved through diagnosis and treatment in both inpatient and outpatient healthcare settings, often with little time for thoughts about self-determination or consideration of quality-of-life decisions. In addition, disparities in access

Source: Gene J. Puskar/AP Images.

Figure 43–1 >> At this clinic in Pittsburgh, Pennsylvania, patients not only receive healthcare, but also are helped to find a place to take English lessons, the closest Hispanic grocery store, and anything else they might need.

and quality of healthcare, particularly for underserved ethnic minority and socioeconomically disadvantaged populations or those with poor literacy, are apparent in the U.S. healthcare system. These patients have additional difficulty navigating the system, and they lack the resources to make quality decisions about their care. Even patients who are competent in terms of English literacy, and/or who have advanced education, may have issues with healthcare literacy and a need for information provided in plain language. All of these patients, as well as their families and support systems, need assistance and empathy to help them manage information about their diagnosis, determine the best course through their treatment plan, and penetrate the layers of bureaucracy to access the required resources (**Figure 43–1** >>>).

As an advocate, the nurse provides patients with much of the information they need to make informed healthcare decisions and supports patients' right to decide. Ideally, medical treatment decision making is shared between the patient and the PCP. When the patient makes decisions other than what is recommended by the PCP, the nurse can help mediate further conversation between the two and ensure that the patient is making an informed decision. The nurse advocates for the patient's right to make autonomous choices, even when those choices are incongruent with the nurse's own beliefs and values. The nurse-advocate must be careful to remain objective and respect the patient's choices without conveying approval or disapproval.

Attributes of the Nurse-Advocate

Although patient advocacy is considered to be an essential nursing function, supported and reinforced in contemporary nursing codes of conduct (American Nurses Association Scope and Standards of Nursing Practice [ANA, 2010]; ANA Code of Ethics for Nurses with Interpretive Statements [ANA, 2015]; and International Council of Nurses

Code of Ethics for Nurses [ICN, 2012]), perspectives on how to approach patient advocacy and the boundaries of advocate roles are open to discourse. Questions have been raised historically (Hyland, 2002; Schwartz, 2002), and continue to appear in current nursing and healthcare literature (Cole, Wellard, & Mummery, 2014), regarding the definition of patient advocacy and whether advocacy means supporting any healthcare decision the patient might make, regardless of its rationality or the extent of the resources available. Additional questions include the potential for advocacy to interfere with autonomous decision making, as well as whether nurses are the only healthcare professionals with a duty to safeguard patients' right to decide. Hyland's (2002) seminal discussion on advocacy asked the question, "Do nurses, in fact, have any right to assume a unique position as a patient advocate among a multitude of health professionals?" (p. 472). Bu and Jezewski's mid-range theory of patient advocacy (2007) has become the "gold standard" from the nursing point of view. This theory acknowledges the importance of patient advocacy as an essential nursing role and provides a clear definition. According to the authors, "patient advocacy is viewed as a process or strategy consisting of a series of specific actions for preserving, representing and/or safeguarding patients' rights, best interests and values in the healthcare system" (p. 104).

The overall goal of patient advocacy is to create an environment in which patients can exercise their right to decide, and in which those rights can be protected, regardless of the environment or setting. Patient advocacy is complicated, because of the complexity of healthcare and legal systems, and also because healthcare decision making is dependent on multiple patient-specific factors. Therefore, the nurse's actions to advocate for any patient must be individualized and depend on the clinical and situational context (Bu & Jezewski, 2007). Within each individual context, three broad core attributes of advocacy form the foundation for action:

1. Safeguarding patients' autonomy
2. Acting on behalf of patients
3. Championing social justice in the provision of healthcare (Bu & Jezewski, 2007).

Safeguarding Patients' Autonomy

Safeguarding patients' autonomy is the first core attribute. It requires respecting and promoting each patient's right to self-determination, except in those situations when the patient is incompetent to decide or does not wish to be involved in decision making (see the Focus on Diversity feature on Patient Autonomy). Safeguarding the autonomy of a patient includes specific actions that both respect and promote the patient's ability to make healthcare decisions. For the patient to be able to exercise autonomy, two assumptions must be made. First is that the patient holds primary responsibility for her own health and decision making. Second is that the patient is legally competent to make healthcare decisions. The patient will likely need information to reach an informed decision; however, for this core attribute to apply, the patient's competency to decide cannot be in question (Bu & Jezewski, 2007). Examples of effective

nursing actions that safeguard patients' autonomy include (Bu & Jezewski, 2007):

- Encouraging patients to share and document their goals, preferences, values, and beliefs
- Supporting patient values and choices even when they conflict with those of individual healthcare providers
- Providing patients with sufficient, timely information for making informed decisions about healthcare, assuring a match between patients' health information literacy and the information provided.

Acting on Behalf of Patients

The second core attribute consists of acting on behalf of patients. When patients are unable to act on their own behalf, or do not wish to represent themselves in the decision-making process, a series of advocacy actions can both preserve and represent the patient's values, benefits, and rights. Examples of situations in which this core attribute applies includes periods during which patients are under anesthesia/sedation or when patients make a conscious choice to have an advocate act on their behalf. Acting on behalf of patients differs from safeguarding patient autonomy, and the two do not conflict because the nurse is advocating for patients who are in very different circumstances (Bu & Jezewski, 2007). If a patient lacks decision-making capacity (e.g., the patient with advanced dementia or the unconscious patient), is legally incompetent, or is a minor, a designated healthcare surrogate or legal guardian is usually appointed to act on behalf of the patient (see the module on Legal Issues for more information).

Focus on Diversity and Culture Patient Autonomy

Patient control over health decisions is a Western view that is not necessarily accepted in other cultures. In other societies, such as the Hmong population, health decisions may be made by the head of the family, a member of the community, or a religious leader. Some Hmong families make their healthcare decisions depending on how they classify their illness based on symptoms (for example, whether the cause is physical or spiritual) and their beliefs about the effectiveness of Western or traditional treatment for the problem. Religious leaders are then called on to decide how to treat spiritual health problems (Lor et al., 2016). In traditional Vietnamese families, husbands make decisions beyond the home, but wives make family healthcare decisions as a part of caring for the home and children (Centers for Disease Control and Prevention [CDC], 2012). The nurse must respect the patient's and family's views and honor their traditions regarding healthcare decision making. Even within the United States, a variety of American cultures and traditions may practice healthcare customs that are unfamiliar to the nurse. In American cultures such as Appalachia, fatalistic beliefs are common and affect the likelihood that people will receive preventive care. For example, some Appalachian women are less likely to complete a full HPV vaccine series, and therefore have higher rates of cervical cancer (Vanderpool et al., 2015). The ethics of advocacy require that the nurse honor the patient's and family's values, preferences, expressed needs, and right to self-determination.

Examples of advocacy interventions in which the nurse acts on behalf of patients include (Bu & Jezewski, 2007):

- Monitoring the quality and safety of healthcare delivered to the patient
- Taking action to intervene if the nurse has information that a treatment or intervention may violate the patient's wishes, directives, or best interests, when appropriate
- Expressing patients' wishes when patients cannot do so for themselves (e.g., during procedures requiring anesthesia/sedation)
- Ensuring that patients who are incompetent to make autonomous decisions have appropriate legal representation (e.g., power of attorney, guardianship).

Championing Social Justice in Healthcare

Championing social justice in the provision of healthcare is the third core attribute of advocacy. This attribute is based on the ethics of justice (see the module on Ethics). Whereas the first two core attributes represent nursing advocacy at the microsocial level (i.e., working with individual patients), this core attribute represents nursing advocacy at the macrosocial level. This attribute calls for nurses to become social activists by becoming involved in matters of health, education, and welfare related to the patients they serve in their organizations, community, or the larger society (Bu & Jezewski, 2007). This attribute could be actualized at the committee level in the nurse's organization, or the nurse might become active in her professional association, for example by serving on a legislative committee. Examples of advocacy actions related to championing social justice in healthcare include (Bu & Jezewski, 2007):

- Helping individual patients achieve healthcare goals by mobilizing resources available in the agency and/or community
- Acting on behalf of patients at policy and legislative levels, both within the agency and at the local, state, or federal level or by advocating to eliminate disparities in any area of healthcare.

Empowering the Patient

The patient–healthcare professional relationship has historically been characterized as paternalistic, with the physician or provider generally guiding decision making. However, the cultural ethic in Western healthcare is moving toward empowering patients to make informed decisions (Barr et al., 2015). The advancement of patient empowerment is beneficial for patients, health professionals, and the healthcare system. Patient empowerment has formally taken hold across Europe and is defined as a “process that helps [patients] gain control over their own lives and increases their capacity to act on issues that they themselves define as important” (European Patients Forum [EPF], 2016). The EPF identifies five aspects of empowerment:

1. Self-efficacy
2. Self-awareness
3. Confidence
4. Coping skills
5. Health literacy.

The idea of patient partnership and empowerment is seen as a way to reduce healthcare costs. By engaging patients, diagnosis is reached more quickly, and unnecessary treatment can be avoided (Richards et al., 2013). Strategies to promote empowerment (Elwyn et al., 2012; Vanderpool et al., 2015) include:

- A thorough and sensitive explanation about available options that provides patients with the opportunity to ask questions
- Always addressing the potential benefits and risks when explaining options to patients
- Eliciting the patient's concerns, ideas, and expectations.

These strategies help ensure that patients have the information they need and are especially applicable to nursing because the nurse often has more opportunity to be present with patients when they need time, conversation, and empathy. There are additional ways for nurses to foster patient empowerment. One way is by assisting patients to cultivate responsibility for their own health. Reminding patients that they are at the center of their own care may help them regain a sense of control. Educating patients about responsible and safe avenues for support can also promote patient empowerment; for example, an online support group for adolescents with cancer operated by a hospital may assist in promoting patient empowerment through social media. Using these strategies to empower patients to navigate healthcare decision making will help build a nurse–patient relationship of mutual respect, trust, and confidence.

Collaborating with Other Healthcare Providers

Given the complexity of healthcare systems, collaborating with other providers on the healthcare team as a way to advocate for the patient's needs has developed on a global scale. In its seminal report a *Framework for Action on Interprofessional Education and Collaborative Practice*, the World Health Organization (2010) reported on the countless benefits of collaborative practice, including greater collaborative decision making with patients. The Interprofessional Education Collaborative Expert Panel (2011) defines the concept of interprofessionalism as “the process by which professionals reflect on and develop ways of practicing that provide an integrated and cohesive answer to the needs of the patient/population . . . [I]t involves continuous interaction and knowledge sharing between professionals . . . to solve or explore a variety of . . . care issues all while seeking to optimize the patient's participation” (D'amour & Oandasan, 2005, p. 8). Interagency and interprofessional collaborations as described in the module on Collaboration are essential to making healthcare services work for patients. In some cases, collaboration with advocacy programs can result in additional avenues of instructional, emotional, and financial support for patients. For example, the National Alliance on Mental Illness (NAMI) (www.nami.org) comprises hundreds of local affiliates and state organizations. NAMI provides support for individuals with mental illness and their families, including education, awareness, and advocacy to promote solutions for the nation's mental health crisis and advances for mental health research (NAMI, 2016).

Advocacy Programs

The federal government encourages states to develop advocacy programs to serve as a resource regarding the rights of those with mental illness or disability. Each state designates an agency or group to advocate for the rights of those with mental illness or disability and to investigate reported incidents involving neglect and abuse of these vulnerable patients in public or private mental health treatment settings, research facilities, and nursing homes. For example, Disability Rights North Carolina (www.disabilityrightsnorthcarolina.org) is a federally mandated nonprofit organization charged with protecting the rights of children and adults with disabilities living in North Carolina (NC). Another example, Disability Rights Ohio (www.disabilityrightsohio.org), a nonprofit corporation, is a federally mandated Protection and Advisory System for Individuals with Mental Illness (PAIMI).

The U.S. military has been faced with a number of health policy challenges, and subsequently has instituted advocacy measures for veterans and active duty personnel. Military personnel are at high risk for developing mental health conditions, one of which is posttraumatic stress disorder (PTSD). Those at risk for PTSD include individuals who have experienced deployment for long periods of time associated with extreme combat conditions. The Department of Defense developed baseline mental health standards military personnel must meet prior to deployment, and also post-deployment assessment screening standards, so persons at risk can be referred for treatment (Murray & Chaffee, 2014). Nurses working with military personnel, veterans, or others at risk for PTSD should be aware of these standards, as well as other related standards, benefits, and interventions available to these patients.

Professional and Public Advocacy

Professional nursing organizations advocate at the state and national levels for the profession of nursing, for its members, and for those who benefit from the services nurses provide. Professional organizations include the American Nurses Association (ANA) and are discussed in the module on Health Policy. As advocates, nurses are in a position to promote and effect change. They need to understand the ethical issues in nursing and healthcare and to have an understanding of state and federal laws and regulations affecting nursing practice and the health of society.

Nurses may advocate as individuals speaking on their own behalf, or they may be asked to speak as a representative of their professional association. There are multiple and varied opportunities to speak publicly for the health, welfare, and safety of patients, to take steps to protect patient rights, to inform the public about issues and concerns by writing articles for the popular press, to lobby state legislators or congressional representatives on behalf of better healthcare for all people, and to run for political office. Gains made by nursing in developing and improving health policy at the organizational, institutional, and governmental levels help to achieve better healthcare for the public.

Advocating for Children and Families

To be an effective advocate for children and families, the nurse must be aware of the child's and family's needs, the family's

resources, and the available healthcare options. The nurse should ensure that the family has adequate information about treatment options and that information is provided at a level matched with their health literacy and appropriate to the child's level of understanding. Treatment options should be in accord with the family's values and resources. Collaboration with other members of the healthcare team is essential, particularly if the family situation is complex, the healthcare issue has significant consequences, or the family's resources are minimal. If the nurse has the best information about these factors from the child/family point of view, communicating this information to the PCP and any other member of the healthcare team who will be helping to facilitate the child's care is essential. The nurse can then play an important role in assisting the family and the child to make informed decisions and to act in the child's best interests. As an advocate for the child and family, the nurse must also intervene to prevent any potential or real harm during planning or treatment and must follow through in whatever way is most appropriate and matched to the situation.

Ensuring that the policies and resources of healthcare organizations meet the psychosocial needs of children and their families is also a part of nursing's role. For example, membership on a committee that develops policies or evidence-based practice guidelines, or a team planning modernization of the healthcare facility design, allows the nurse to contribute knowledge of the developmental and psychosocial needs of children that can help ensure that the organization addresses the needs of children and families (Figure 43-2 »).

Table 43-1 » lists some examples of how nurses can advocate for children and families in their community.

Figure 43-2 » Nurses must be aware of the needs of pediatric patients for play time and advocate for children to have play time as well as rest time and appropriate nutrition. Here, a volunteer grandmother plays with a young boy to provide stimulation and nurturing during his lengthy hospitalization.

TABLE 43-1 Advocating for Children and Families

Health Need Example	Nurse Advocacy Actions
Members of the community need information about places to obtain immunizations.	<ul style="list-style-type: none"> ■ Make a list of agencies that provide immunizations, including those with low-cost immunizations through the Vaccines for Children program. ■ Obtain financial assistance from a local foundation to print your findings. ■ Make copies available in child care centers and other community agencies.
A local homeless shelter has little in the way of self-care amenities for the patients.	<ul style="list-style-type: none"> ■ Obtain donations of hotel lotions, soaps, and shampoos from classmates and faculty that can be given to the shelter. ■ Visit several local hotels and ask whether they will each donate a box of small toiletries for the residents. ■ Encourage volunteers to provide haircuts and styling, or obtain donations to provide this service.
Your state has a law protecting the rights of any woman to bring her unwanted newborn baby to certain sites for the purpose of giving up her child without legal recriminations. Because many women do not know about the law, babies are abandoned in unsafe locations.	<ul style="list-style-type: none"> ■ Find a local newspaper reporter who is willing to write an article about the law. ■ Run off copies of the article to distribute. ■ Make posters with necessary information for several community sites and the emergency department.

Upper Saddle River, NJ: Prentice Hall. Reprinted and electronically reproduced by permission of Pearson Education, Inc., New York, NY.

Advocating for Vulnerable Populations

Vulnerable populations generally include groups who are at greater risk for disease, disability, and reduced lifespan because of a lack of resources, risk factors, or a combination. These groups often include the socioeconomically disadvantaged, such as low-income seniors, younger persons with either physical or mental health-related disabilities, and individuals of limited English proficiency. Many older individuals in vulnerable groups are considered "dual eligible," in that they are enrolled in both Medicare and Medicaid programs. These individuals—who consist of the sickest and poorest patients, with higher rates of diabetes, pulmonary disease, stroke, mental health disorders, and Alzheimer disease—must navigate both government programs to access the services they need. In its most recent report on vulnerable populations, the American Hospital Association reported that approximately 9.2 million individuals were classified in this highly vulnerable "dual eligible" category. New care coordination models have developed to help vulnerable older adults receive home-based care and improve care coordination, and they ensure integration of cultural competency and care equity standards (American Hospital Association, 2011).

Source: Stockbyte/Getty Images.

Figure 43-3 Patients in long-term care facilities are often unable to advocate for themselves. Nurses should advocate for these individuals in many areas, including effective pain control.

An additional category of vulnerable populations is patients who serve as research subjects. The National Institutes of Health established vulnerable research subjects categories in 2005 that are currently in effect. These include pregnant women, human fetuses and neonates, prisoners, and children (National Institutes of Health, 2005). Nurses are strong advocates for all of these vulnerable populations, both those in their care and those who are the subjects of healthcare research.

In the twenty-first century there is a need for new energy and political activism to ensure that the needs and the rights of individuals representing vulnerable populations are not overlooked. Advances in science, technology, and evidence-based practice continue to revolutionize how nurses practice (Figure 43-3), and nurses must continue to advocate for fair and equitable access to high-quality care for all patients in a variety of settings, including acute care, free clinics, and primary care and specialty practices.

Clinical Example A

Lois Potter is a 78-year-old woman with a number of medical conditions, including type 2 diabetes mellitus. She is seen regularly in a community-based primary care clinic. The nurse practitioner has just talked with Mrs. Potter about the fact that her lab values indicate she needs to switch from the oral antidiabetic medication she has been taking to insulin injections. Mrs. Potter knew this was a possibility, but she is distressed about glucose monitoring and self-injection. Mrs. Potter is on a very limited income and is insured by Medicare and a supplemental policy. The RN working alongside the nurse practitioner teaches her self-injection in the office, but Mrs. Potter's return demonstration is worrisome.

Critical Thinking Questions

1. What information should the nurse communicate to the healthcare team regarding Mrs. Potter's injection competency?

Which team members should be a part of this collaborative conversation?

2. What options does the nurse have for advocating that Mrs. Potter receive follow-up home care until she is comfortable with self-injection?
3. How can the nurse advocate for the patient in a way that maintains Mrs. Potter's dignity?

Two federal laws ensure the rights of individuals with disabilities. The Patient Self-Determination Act (PSDA) was enacted in 1991 to require healthcare institutions to inform patients of their healthcare decision-making rights, and the institution's policies regarding recognition of advance directives. This law provided general protection rights to all patients, including those with disabilities (see the module on Legal Issues for more information about the PSDA). However, the Americans with Disabilities Act (ADA), first enacted in 1990, is a civil rights law that ensures people with disabilities have the same rights as everyone else. It prohibits discrimination against individuals by providing federal protection to those with physical and/or mental health disabilities, in areas of public life such as employment, schools, transportation, and both public and private places open to the general public. Amendments to the law made significant changes to the definition of "disability" and became effective January 1, 2009 (ADA National Network, n.d.).

Clinical Example B

Ms. Marina Smith is an RN with 20 years of clinical experience. While caring for a patient on the orthopedic unit, Ms. Smith injures her back and is no longer able to work on a clinical nursing unit. During a visit to her PCP for follow-up care, Ms. Smith explains that although she is currently on medical leave, she is no longer able to function as a staff nurse on the orthopedic unit, or any unit that will require lifting or moving more than 20 pounds. She is uncertain what next steps her career can take, and she is very concerned. She reports that she applied for a position at a different hospital, but did not get an interview when the agency discovered she had physical limitations. She has not yet had a conversation about her predicament with her supervisor, so she does not know if options are open to her at her existing workplace.

Critical Thinking Questions

1. What would you say to Ms. Smith at this time?
2. If you were Ms. Smith's nurse, what would be the most appropriate way to advocate on her behalf? Explain your answer.
3. With whom on the healthcare team would you collaborate to be sure Ms. Smith gets the care she needs?

Nurses should be aware of the rights of two categories of individuals with disabilities: the physically disabled and those with cognitive disabilities. The prevalence of individuals with disabilities is staggering, and it crosses the lifespan. Seventy percent of students in public schools who are either secluded or physically restrained have disabilities, and 60% of individuals in jail have some type of mental disability. In addition, these individuals are socioeconomically disadvantaged: 48% have a personal annual income of \$15,000 or less (American Civil Liberties Union, 2016).

Individuals with mental health issues are particularly vulnerable to abuse and neglect, either in their communities or in mental health settings that provide substandard care. The nurse's role is to advocate for the disabled person's

physical, sexual, and emotional safety, both in the community setting, during institutionalization, or during a short-stay admission or outpatient visit. Their rights include (Disability Rights of Ohio, 2016):

- Personal rights, including the right to safety with people they know, including family, staff, and strangers.
- The right to be respected and treated with dignity.
- The right to have or not have a sexual relationship, including the right to permit or deny another person's touch.
- The right to control their money and possessions, including items such as cigarettes and clothing.
- The right to treatment in a place that respects their freedom and includes a current, written treatment plan that the patient participated in creating.
- The right to refuse or accept a suggested medication. In most states, psychiatric facilities cannot force patients to take medication except in an emergency.
- The right to exercise these rights without punishment, withholding of treatment, loss of privileges, or physical/emotional abuse.
- The right to a living space that provides reasonable protection from harm, including physical or emotional abuse and the use of overmedication or excessive restraint.

Clinical Example C

Mr. William Johnson is a 53-year-old patient being seen in the outpatient clinic for treatment of an acute exacerbation of chronic bronchitis related to his chronic obstructive pulmonary disease (COPD). He is also being treated for schizophrenia. He takes the medication he receives from the clinic because he wants his symptoms to remain under control, but he doesn't like the side effects. He has been a smoker for 40 years and has no intention of stopping. He is currently living with several other men in a housing project, and he has an entry-level job at a local fast food restaurant. Mr. Johnson has been disciplined by his generally understanding employer several times for behavior issues, but during his examination he tells you he fears being sent back to the mental health facility. On his last admission, the night staff who had previously treated him well during past admissions had been replaced by two new "orderlies" (psychiatric technicians). When the nurse was on another unit, one of them restrained him in his bed when he refused to share his cigarettes with him.

Critical Thinking Questions

1. How is this action by the psychiatric technician a violation of Mr. Johnson's rights?
2. What is the nurse's next step in advocating for Mr. Johnson?
3. Is this an example of advocacy at the level of the individual patient, at the community/policy level, or both?

Although laws protect basic healthcare rights and those of the disabled, miscommunication among providers and patients, and medical error, may still occur. Even when the letter of the law is followed, the spirit of the law may not be satisfied, particularly when working with patients with disabilities. For example, even if a patient reads and signs an informed consent document, comprehension of the information may be incomplete or absent. Nurses are often in a position to ensure that the procedures for procuring informed consent conform to both the letter and spirit of the law, particularly in the matter of patients with mental disabilities severe enough that capacity is questionable or incompetency

has been determined. In these cases, the patient's guardian, or individual with durable power of attorney, should be present and engaged in the informed consent process on the patient's behalf. Note that the nurse may not legally serve in that role; to do so would be considered a conflict of interest and could result in consequences for both the nurse and the organization. However, nurses are uniquely sensitive to the complex biopsychosocial issues involved in coping with disabilities, and they are in a position to advocate for these patients as they navigate the healthcare system. If the nurse discovers that the patient is not competent to make healthcare decisions, and no durable power of attorney is on record, the nurse should contact the PCP and may also need to work with social services to ensure that the appropriate next steps occur.

Advocacy Interventions

Novice nurses need to understand the organization in which they work, appreciate the legal implications of their actions, and carefully think through options before advocating on behalf of patients. In addition, it is essential that nurses anticipate patients' advocacy needs. Even a quick assessment can reveal the extent of the patient's understanding of their health problem, their plan of care, their health literacy, support system, and coping ability *in that moment*. Then the nurse can plan initial advocacy interventions accordingly. It is always necessary to safeguard the patient, but action must be taken in context. In designing and conducting advocacy interventions, it is important to do the following:

- Assess the patient's ability to cooperate and to make decisions.
- Assess the reliability of information provided *by the patient*, with regard to health history and family situation, especially if the patient exhibits impairment of cognitive function or mental instability. When necessary, engage family members as partners, or if appropriate, ensure the presence of the guardian or person with durable power of attorney.

Specific advocacy interventions may include:

- Educating patients and their families about their legal rights regarding informed decision making
- Ensuring patients have a voice in their care and are intentionally engaged in shared decision making by all providers involved in their care
- Ensuring that patients have the necessary information to give informed consent
- Monitoring patients' care to safeguard patient rights
- Evaluating organizational policies and procedures to ensure protection of patient rights
- Intervening if other healthcare professionals provide care that does not consider the patient's stated preferences and values or does not engage the patient in the decision, if the patient is competent to decide.

Concepts Related to Advocacy

Nurses must take many other concepts into consideration when advocating for their patients. Examples include ethics, legal issues, professional behaviors, culture and diversity, and healthcare systems.

Concepts Related to Advocacy

CONCEPT	RELATIONSHIP TO ADVOCACY	NURSING IMPLICATIONS
Cellular Regulation	↑ advocacy → ↑ awareness of individual and global needs, as well as ↑ funding for research and treatment needs	<ul style="list-style-type: none"> Nurses ensure access to treatments and services, that holistic needs are met, and that patients do not face discrimination based on their health issue. Nurses advocate, nationally or locally, for cancer research funding or for community cancer patient-friendly services.
Culture and Diversity	By advocating for patients' cultural and religious preferences, nurses ↑ patient satisfaction with care, promote the therapeutic relationship.	<ul style="list-style-type: none"> The nurse should practice culturally competent care by respecting the unique patient values and advocating for patient's rights to culturally competent care provided by healthcare organization, systems, and providers. Nursing advocates should respect the patient's diversity and promote equity of care.
Ethics	Ethics → advocacy, ↑ patient safety and autonomy	<ul style="list-style-type: none"> The nurse's primary commitment is to the patient. The patient should trust that the nurse will act on behalf of the patient's best interests. Nurses have an obligation to intervene when ethical dilemmas arise. The nurse should call ethical dilemmas to the attention of the PCP, the healthcare team, and the organization's ethics committee, as necessary and appropriate. The nurse protects the patient's right to make choices about care and to refuse treatment.
Healthcare Systems	Vulnerable patients experience ↑ barriers to access and ↑ challenges and discrimination.	<ul style="list-style-type: none"> The nurse should support the patient by advocating for their right to access and receive equitable care in the healthcare system.
Legal Issues	Nurses who advocate ↑ patient safety and autonomy ↓ risk for negligence or error, ↑ trust in the profession.	<ul style="list-style-type: none"> The nurse-advocate should uphold the rights of the patient in any situation and also monitor the care provided by other professionals caring for patients. The nurse has an obligation to report any unethical or illegal behavior by another nurse, healthcare provider, or other staff member.
Mobility	Advocacy is necessary to improve patient and caregiver understanding, ↓ risk for further injury or immobility, ↑ patient and caregiver quality of life.	<ul style="list-style-type: none"> Nurses ensure patients have access to appropriate care, mobility devices, and live in mobility-restricted safe environments. Nurses may advocate at the national, state, or community level for patients with mobility limitations, e.g., for research funding, or to ensure public place accessibility.
Professional Behaviors	By acting professionally, nurses ↑ their credibility, thereby ↑ opportunities and chances for successful advocacy.	<ul style="list-style-type: none"> The nurse should continuously advocate for the patient as a component of the professional scope of practice. The nurse-advocate should act in accordance with professional and ethical standards.

As stated earlier, the nurse's role as an advocate is based in nursing codes of ethics, a system of principles or standards that governs nursing behaviors and relationships, guiding right conduct. Ethics and morals are related—morals are the principles on which judgments about right or wrong are based from a personal point of view. The role of the advocate is to uphold nursing's ethical principles.

Legal issues encompass the rights, the responsibilities, and scope of nursing practice as expressed in national standards of care, state practice acts, and associated rules (regulations). All patients have the right to expect safe, effective, competent nursing practice.

Patients have the right to exercise their individual cultural beliefs and values and to have their unique health

needs met. Nurses who advocate for culturally competent care, both in specific individual situations and in everyday practice, help ensure that patients' cultural beliefs, values, and needs are respected. In turn, this increases patient satisfaction with care and promotes the therapeutic relationship.

Access to healthcare remains challenging to millions of Americans. In many rural settings, for example, access to specialty care and quality mental healthcare is limited. Nurses who work in areas or with patient populations with limited access can advocate for their patient or region by seeking ways to collaborate with other agencies, advocating for increased funding from their local legislators, and advocating for affordable alternatives, such as telemedicine, as ways to improve and promote patient access to healthcare.

The nurse's duty to advocate on behalf of patients requires careful collaboration in the form of clear and continuous communication with the patient, family members, and other healthcare professionals on the decision-making team. It is important to remember to balance the role and duty of advocacy "watchdog" with an attitude of teamwork when it comes to working alongside other professionals on the healthcare team. For example, a busy consulting physician may engage a patient in a one-on-one discussion about a treatment option and obtain written informed consent, unaware that the patient was recently medicated with an opioid drug to manage pain and is having difficulty both concentrating and remembering. The nurse's role would be to inform the physician and together with the physician decide whether a family member of the patient's choice should be present for a rescheduled conversation, wait until such time as the effects of the opioid did not affect decision making, or both. Regardless, a time for the physician to repeat the conversation should be scheduled, and the consent form signed again. The nurse would document the facts in the patient's record. The duty of advocacy is then fulfilled, the patient's rights safeguarded, and a collaborative nurse-physician relationship established or advanced.

Patients with alterations in cellular regulation, especially any type of cancer, need strong advocates. At the microsocial level, nurses help ensure that patients have access to necessary treatments and services and that patients' holistic needs are met. For example, nurses working with children with cancer advocate that patients have access to playtime and help their parents find ways to continue their schooling. At the macrosocial level, nurses may find themselves advocating through professional organizations for increased funding or may advocate at their agency level for play areas that can accommodate pets.

Patients with alterations in mobility, particularly those who depend on the use of mobility assistive equipment, also need strong advocates. At the microsocial level, nurses ensure that patients have access to the equipment and devices they need, and accompanying treatments, services, and personnel who can assist them with activities of daily living, if necessary. Nurses can advocate for affiliate home healthcare agencies to ensure that the patient's home environment is safe relative to their mobility limitations. At the macrosocial level, nurses may advocate through their professional associations to increase funding for

research and care for mobility-related health issues, or work with community organizations to ensure accessibility to public places is accommodated. The Concepts Related to Advocacy feature links some, but not all, of the concepts integral to advocacy. They are presented in alphabetical order.

Unethical or Unsafe Practice or Unprofessional Conduct

Nurses have a legal responsibility to intervene on behalf of any patient if they have reason to believe that another professional is engaging in practice that is unethical, unsafe, substandard, or unprofessional. State nurse practice acts include sections regulating the actions of the nurse in this regard, as well as reporting requirements. However, if the professional in question is not a nurse, the nurse should still intervene to safeguard the patient. The nurse who needs to intervene to protect a patient will follow established reporting procedures for her agency or facility, but the first step is to notify the nurse's own direct supervisor—the person to whom the nurse reports directly. That individual can be essential in assisting the nurse who discovered the breach of conduct and in facilitating the reporting procedure. That person is also the nurse's resource if immediate assistance is needed to stop an unsafe practice before harm is done to the patient.

Common examples of unethical or unsafe conduct that require nurses to advocate with one another or on behalf of a patient include boundary violations and nurses or team members working under the influence of drugs or alcohol. Boundary violations, such as engaging in an inappropriate relationship with a patient or coercing or restraining a patient to benefit the professional in some way (as in Clinical Example B in this module), are included in the category of ethical issues that may be addressed by a state board of nursing. Both state nurse practice acts and the ANA Code of Ethics require nurses to report unethical nurse behaviors, including boundary violations.

Impairment of a coworker or team member is the most commonly encountered situation that combines unethical, unsafe, and unprofessional conduct. Impairment to practice may be the effect of a substance—legal, illegal, prescription, or over-the-counter. Impairment to practice safely may also result from extreme emotional distress (e.g., a nurse who returns to work too soon following the death of a close family member). Because impairment has the potential to interfere with safe clinical practice, the nurse who observes or suspects impairment in any other health professional, nurse or non-nurse, is obligated to immediately report to a supervisor (ANA, 2010). For more information, including warning signs that indicate impairment, please see the section on Impaired Nurses in the module on Addiction.

A growing concern in healthcare regulation is the violation of a patient's privacy related to the inappropriate use of social and electronic media by healthcare providers. Nurses must consider confidentiality and privacy laws, patients' rights to be treated with dignity and respect, and trust as a foundation for nurse-patient relationships. Whether or not a post was an unintentional or nonmalicious act, posting confidential information about patients, including any health-related facts, conversations, or photographs, constitutes a

breach of privacy. Such action may subject a nurse to disciplinary action by both the employing institution and the state board of nursing. In addition, the nurse may be subject to civil and criminal penalties. In response to alarm about this increasingly widespread practice, the National Council of State Boards of Nursing published its seminal White

Paper on the use of social media (National Council of State Boards of Nursing, 2011). It is important that nurses work with their colleagues to keep one another attuned to the inappropriateness of using social media in this way, advocate for patient privacy and protection, and if aware, report infractions.

REVIEW The Concept of Advocacy

RELATE Link the Concepts

Linking the concept of advocacy with the concept of culture and diversity:

1. Consider each of the groups included within the description of vulnerable populations, and provide examples of how the nurse can advocate for each.
2. Why might patients with values and beliefs that differ from the mainstream population require greater efforts with regard to advocacy?

Linking the concept of advocacy with the concept of ethics:

3. How does the ANA Code of Ethics with Interpretive Statements (ANA, 2015) address advocacy? Under what circumstances might a nurse experience conflict of interest when advocating for a patient? Is the nurse the sole healthcare provider taking on the advocacy role; i.e., how do nurses balance the unique contributions of the profession with the team approach?
4. Differentiate between the nurse's role of advocate for individuals who are temporarily unable to speak for themselves (e.g., persons under anesthesia) versus the role of advocate for those who are competent to speak for themselves but, for whatever reason, do not.

Linking the concept of advocacy with the concept of legal issues:

5. What is the nurse's advocacy role when caring for a patient who is not competent to make healthcare decisions? Provide examples of other members of the healthcare team or organization who could be helpful in ensuring that the patient's advocacy needs are met.
6. How does the nurse practice act in your state address reporting of unethical or unsafe practice, or boundary violations (e.g., posting

patient healthcare information on social media). Is the reporting requirement for licensees (i.e., nurses), employers, or both?

REFLECT Apply Your Knowledge

Heather Adams is a neighbor in your apartment building. On week-ends, the two of you sometimes get together for morning coffee. Last weekend, Ms. Adams shared a concern that has been troubling her for a few weeks. She is 31 years old and unmarried, and she lives alone. Her father is deceased, and her mother, who was diagnosed with Alzheimer disease several years ago, is now a resident in a long-term care facility for people with cognitive impairments. Ms. Adams is estranged from her only brother. When she was in her early 20s, Ms. Adams was hospitalized and treated for depression. Her fear is that, should she become incapacitated again with depression, the brother whom she actively dislikes and with whom she does not get along will make treatment decisions as her next of kin.

You have decided to invite Ms. Adams for coffee. Because Ms. Adams seems to be an individual who would benefit from a healthcare power of attorney, your intent is to have a conversation with her about her choices.

1. On what basis do you act as an advocate for Ms. Adams (i.e., as a neighbor/friend, or as her nurse)?
2. Would it be ethical for you to serve as the surrogate decision maker? Explain your answer.
3. In your discussion with Ms. Adams, should you encourage her to see an attorney? Explain your answer.

Exemplar 43.A Environmental Quality

Exemplar Learning Outcomes

43.A Analyze the health indicator of environmental quality as it relates to advocacy.

- Outline the components of environmental quality.
- Summarize the major impacts of environmental quality on public health.

- Describe community responses to alterations in environmental quality.
- Explain the nurse's role in advocating for patients affected by environmental quality.

Exemplar Key Terms

Environmental health hazards, 2724

Environmental quality, 2724

Overview

Environmental quality is one of the 12 leading health indicators published in *Healthy People 2020*. Its effect on health status is direct. For example, premature death, cancer, and long-term damage to respiratory and cardiovascular systems

are all linked to poor air quality (Office of Disease Prevention and Health Promotion [ODPHP], 2016). **Environmental health hazards** include natural or human-made substances, states, or events that affect the natural environment, produce negative effects on the human ecosphere, and adversely

affect health. Air and water pollution are the two most common environmental health issues, and the data regarding exposure is staggering. *Healthy People 2020* reports that approximately 127 million people in the United States live in counties where air pollution exceeds national air quality standards, and 88 million nonsmokers are exposed to secondhand smoke annually (ODPHP, 2016). These issues and many others affect the health of citizens in the United States and globally; the actions of nurse-advocates focused on environmental quality can have profound effects.

Classification of Environmental Hazards

Healthy People 2020 and the CDC categorize environmental quality and its determinants differently; together, these classifications provide an overview of the breadth of environmental factors that affect the nation's health. These lists are provided in **Table 43-2** ».

The two most common environmental health hazards are air and water pollution (CDC, 2016b). A key factor in air pollution is the level of ground-level ozone, which is a component of smog. Ground-level ozone is often responsible for increases in emergency department visits and hospitalizations for individuals with health problems associated with diminished lung function, such as asthma and chronic obstructive lung disease. Individuals at higher risk are those who live in geographic areas where ground-level ozone is most likely to form at greater levels; contributing factors include heat, concentrations of precursor chemicals, methane emissions, wildfire emissions, and air stagnation (CDC, 2016b). Individuals at higher risk within high-ozone geographic areas include those with diminished lung function, but who are also socioeconomically disadvantaged (e.g., may be without air conditioning during times of high ground-level ozone), the elderly, children, or those with comorbidities.

TABLE 43-2 Determinants of Environmental Quality

<i>Healthy People 2020</i> Determinants of Environmental Quality ¹	CDC Environmental Hazards and Health Effects ²
<ul style="list-style-type: none"> Improving air and water quality Decreasing mental health stresses Strengthening the social fabric of a community Providing fair access to employment opportunities, education, and resources Increasing options for physical activity and healthful diets Decreasing injuries and accidents 	<ul style="list-style-type: none"> Air Pollution and Respiratory Health Asthma Carbon Monoxide Clean Water for Health Climate and Public Health Health Studies, which includes epidemiologic investigations in response to outbreaks believed to have environmental causes, and responding to natural/technologic disasters Radiation Studies, which includes information about both ionizing and nonionizing radiation

² Adapted from Centers for Disease Control and Prevention (CDC). (2016a). *National Center for Environmental Health*. Retrieved from <http://www.cdc.gov/nceh/default.htm>.

Water pollution is also a concern. Water supplies may be contaminated with either natural or human-made substances. Contaminants in the public drinking-water supply that can cause health hazards include, but are not limited to, arsenic, nitrate, radium, uranium, and disinfection by-products (CDC, 2016b). Water pollution includes contamination of water supplies for public use (e.g., drinking water, bathing water) but also includes contamination of water resources, such as the pollution of rivers, lakes, and oceans. Contaminants, garbage, and oil spills are common pollutants of resources that can impact environmental quality over time.

Other environmental hazards include ionizing radiation, a variety of other chemicals such as lead and cadmium (ODPHP, 2016), and noise pollution.

The Effects of Environmental Quality on Public Health

A number of public health problems can be linked to exposure to environmental hazards, including asthma, birth defects, heat stress illness, poor reproductive and birth outcomes, lead poisoning, heart disease, cancer, carbon monoxide poisoning, and developmental disabilities. Three of the most common health effects related to environmental hazards, and their associated environmental links, are shown in **Table 43-3** ».

TABLE 43-3 Selected Health Effects and Related Environmental Hazards

Common Health Problems	Related Environmental Hazards
Asthma	<ul style="list-style-type: none"> Exposure to allergens and triggers, including tobacco smoke, dust mites, furry pets, mold, certain chemicals, and the particulate matter in outdoor air pollution Particulate matter, which includes dust, dirt, soot, and smoke When these pollutants from vehicles, power plants, factories, and other sources come in contact with heat and sunlight, ground-level ozone forms, putting individuals with asthma who spend time outside at greater risk
Birth defects	<ul style="list-style-type: none"> Environmental exposures to substances such as ionizing radiation, some endocrine-disrupting chemicals (e.g., polychlorinated biphenyls, or PCBs), dioxins, and pesticides have been linked to defects of the nervous system and developmental problems Disinfection by-products in drinking water (e.g., trihalomethanes, or THMs) may increase risk for brain and spinal cord, urinary tract, and heart birth defects Living near hazardous waste has been linked to birth defects such as spina bifida, cleft lip/palate, gastroschisis, Down syndrome, and others More data are needed to make clear connections between environmental exposures and birth defects
Cancer	<ul style="list-style-type: none"> Exposure to ionizing radiation Exposure to some industrial chemicals Environmental tobacco smoke (secondhand smoke) It may take up to 40 years of environmental exposure for a cancer to develop

Community Responses to Environmental Issues

A community's citizens are directly affected by local, national, and global environmental issues. One way for citizens to respond is to be empowered to make positive change and become active regarding one or more environmental issues that affect them directly. Communities can serve as activists locally in municipalities, or join larger communities to make a larger impact. For example, the Natural Resources Defense Council (NRDC) is a global group of more than 2 million online activists, including scientists, lawyers, and policy advocates, who work to safeguard air, water, and natural systems. The NRDC identifies six ways to keep water clean, including (1) looking at how water flows across outdoor surfaces and into storm drains; (2) advising against flushing nondegradable products in a toilet or (3) a sink; (4) disposing of pet waste appropriately; (5) regular car maintenance, to reduce leaking of oil, coolant, and antifreeze; and (6) reporting polluters by contacting local environmental groups, such as the Clean Water Network or Waterkeeper Alliance (NRDC, 2016). These are steps that are possible for nurses working with community activist groups to actualize.

Advocating for Patients Affected by Their Environment

Nurses can intervene on behalf of patients affected by environmental quality in a number of ways across a variety of care settings. Nurses working in emergency departments, acute care, and primary care see the effects of environmental quality when they work with patients who experience health conditions affected by, or caused by, environmental hazards (**Figure 43–4**). For example, nurses may care for individuals with asthma or COPD who are admitted with exacerbations during periods of poor air quality. Community/public health nurses are also well positioned to serve as advocates. For example, underserved patients who live in substandard housing may have children at risk for lead poisoning from old peeling paint or old plumbing. Nurses can educate

Source: ZUMA Press Inc/Alamy Stock Photo.

Figure 43–4 Dr. Hanna-Attisha of Flint, Michigan, knew that an investigation of the water quality in Flint showed that it contained dangerous amounts of lead. She decided to conduct her own analysis using hospital records. She found that the number of Flint children with elevated levels of lead had doubled and tripled in some areas since Flint had switched to a new water source 2 years earlier. Dr. Hanna-Attisha was so alarmed that she chose to hold a press conference rather than go through the months-long process of publishing her findings in a medical journal. She said she and her team had “an ethical, moral, professional responsibility to alert our community about this crisis.”

patients about environmental hazards and strategies to safeguard themselves, or develop programs to educate the larger community. Nurses can act locally at the municipal, state, or national level to lobby government officials for change—for example, if community industries are known to be noncompliant with air pollution standards. Professional nursing associations generally identify legislative agendas focusing on state or federal legislation, depending on the scope of the association; as members, nurses can become involved on legislative committees and assist by providing data, or testimony, to support measures that safeguard the environment.

REVIEW Environmental Quality

RELATE Link the Concepts and Exemplars

Linking the exemplar of environmental quality with the concept of ethics:

1. Consider the air pollution exemplar, and how different vulnerable populations, for example children with asthma, might be affected by living in areas prone to high summertime ground-level ozone measurements. What is the nurse's ethical responsibility to advocate for environmental quality that improves the health of vulnerable populations? Provide examples of how nurses could advocate for environmental quality improvement.

Linking the exemplar of environmental quality with the concept of healthcare systems:

2. Why might patients who experience health problems made worse by environmental hazards (e.g., lung disease, heart disease), and

also represent vulnerable populations (e.g., socioeconomically disadvantaged or the elderly), experience barriers to access to healthcare treatment for environmentally related health issues? Consider the Flint, Michigan, water crisis as an exemplar. Why might these patients require greater advocacy?

Linking the exemplar of environmental quality with the concept of legal issues:

3. What is the nurse's role when advocating for the mother of a child with asthma who is living in substandard housing in poor condition with a leak in the roof?
4. What is the nurse's advocacy role when a patient presents with a health problem related to an unsafe work environment, such as constant exposure to toxic fumes?
5. What advantage does professional nursing hold when advocating, as a group, for environmental health and safety?

6. When nurses testify for an environmental quality issue, how do they represent themselves—as an individual, or as a member of the profession?

REFLECT Apply Your Knowledge

Jonathan Baker comes to the emergency department (ED) where you work complaining of difficulty breathing and shortness of breath. He has no other symptoms of upper respiratory disease, no history of chronic lung disease, and otherwise is in good health. As a part of your assessment you ask him about his living conditions, and he tells you that he lives in a subdivision very near the river that has flooded twice during the spring rainy season. The last flood was significant,

and several weeks later, Jonathan and his wife are still working at cleaning up the aftermath. You ask him if he has noticed any musty, earthy smell or foul odor in the house, and he states that he has. He knows that there has been mold growth in the basement and first floor, but he has not had the time to deal with it or to call his insurance company.

You determine that Mr. Baker's respiratory problem is likely due to mold, and you immediately notify the PCP so the diagnosis can be confirmed and his condition appropriately treated.

1. What are your next steps advocating for Mr. Baker's health?
2. Is there any other role in which you might advocate for the health and well-being of other flood victims in your city/region?

Module 44

Ethics

Module Outline and Learning Outcomes

The Concept of Ethics

Values

44.1 Analyze the relationship between values and ethics in nursing.

Concepts Related to Ethics

44.2 Outline the relationship between ethics and other concepts.

Nursing Codes of Ethics

44.3 Differentiate the various codes of ethics used in nursing.

Principles and Practices of Ethical Decision Making

44.4 Analyze the principles of ethical decision making.

Strategies to Enhance Ethical Decisions and Practice

44.5 Summarize strategies to enhance ethical decisions in practice.

Ethics Exemplars

Exemplar 44.A Morality

44.A Analyze morality as it relates to ethics.

Exemplar 44.B Ethical Dilemmas

44.B Analyze dilemmas related to ethics.

Exemplar 44.C Patient Rights

44.C Analyze patient rights as they relate to ethics.

>> The Concept of Ethics

Concept Key Terms

Altruism, 2730	Code of ethics, 2734	Justice, 2736	Social justice, 2730	Veracity, 2736
Autonomy, 2730	Ethics, 2729	Morality, 2729	Values, 2730	
Belief, 2730	Human dignity, 2730			

Ethics, as applied in professional nursing, is defined as a system of moral principles or standards governing behaviors and relationships that is based on professional nursing beliefs and values. More broadly defined, ethics refers to the standards of right and wrong that influence human behavior, usually in terms of rights, obligations, benefits to society, fairness, or specific virtues. Ethical standards are based on the values of the group that holds to those standards, whether the group consists of individuals of the same religion, people from the same community, or individuals who share the same profession. Within the field of nursing, some of the most important ethical standards relate to the rights of patients and their families, such as the rights to privacy and self-determination.

The term *ethics* also refers to the study and development of the ethical standards of an individual, community, or profession. Nurses should constantly examine their personal ethical standards and understand how their personal

ethics and morals compare to the ethical standards of the nursing profession.

Morality (or morals) is similar to ethics, and many people use the terms interchangeably. However, **morality** usually refers to private, personal standards of what is right and wrong in conduct, character, and attitude. Sometimes the first clue to the moral nature of a situation is the awareness of feelings such as guilt, hope, or shame. Another indicator is the tendency to respond to the situation with words such as *ought*, *should*, *right*, *wrong*, *good*, and *bad*. Moral issues are concerned with important social values and norms; they are not about trivial things.

Just as nurses should be able to distinguish between ethics and morality, they should be able to distinguish between morality and law. Laws reflect the moral values of a society and offer guidance in determining what is moral; however, an action can be legal but not moral. For example, an order for full resuscitation of a dying patient is legal, but one

could still question whether the act is moral. Conversely, an action can be moral but illegal. For instance, if a child stops breathing at home, it is moral but not legal to exceed the speed limit when driving to the hospital. (Legal aspects of nursing practice are covered in depth in the module on Legal Issues.)

When people are ill, they may be unable to assert their rights as they would if they were healthy. When this happens, nurses have an ethical responsibility to advocate on behalf of the patient based on what the patient would want. An **advocate** is a person who expresses and defends the cause of another person. Therefore, the nurse advocates for the patient's best interest on the basis of the patient's values, not on the basis of the nurse's own ethical or moral values. Nursing advocacy takes many forms and is discussed in detail in the module on Advocacy. However, to function successfully in his or her capacity as an advocate for patients, each nurse needs an understanding of ethical issues in nursing and healthcare.

Values

Values provide the foundation on which an individual's or group's ethical standards are built. Guido (2014) defines **values** as "personal beliefs about the truths and worth of thoughts, objects, or behavior" (p. 32). A **belief** is an interpretation or conclusion that one accepts as true. Values can reflect both beliefs that are based on a particular tenet (doctrine) or body of tenets accepted by a group of individuals and beliefs that are based on a pattern of mental views established by cumulative prior experience. For example, many traditional Jewish beliefs are based on the tenets found in the Jewish Torah, but individual Jews may hold other or additional beliefs based on their own experiences. Personal values are developed through individual observation and experience and may be heavily influenced by social traditions and the cultural, ethnic, and religious norms experienced within a person's family and associated groups.

Nurses acquire professional values through socialization into the nursing profession by nursing school faculty and other nurses, through clinical and life experiences, and by following established professional codes of ethics. As part of this socialization, nurses develop insight into their own values and how their values influence their actions. One of the most helpful ways for nurses to develop such insight is through **values clarification** (Johnstone, 2012a). Through this process of consciously identifying, examining, and developing individual values, nurses gain the ability to choose actions on the basis of deliberately adopted values.

Values clarification is important to both nurses and patients in supporting the provision of patient-centered care, because it helps nurses learn how to identify patients' values and distinguish patients' values from their own (Yoost & Crawford, 2016). Values clarification is not a once-in-a-lifetime activity but an ongoing process of examining what one's values are and how these values inform or affect one's decisions and actions. Nursing students and professional nurses alike need to have a clear sense of their values specific to life, death, health, and illness. Values clarification

exercises and real-life experience in carrying out treatment plans that contradict or challenge their beliefs about patients' best interests will assist nurses at all levels to develop expertise in responding to ethical issues.

Values Essential for the Professional Nurse

Although each nurse ultimately has his or her own unique set of personal values, certain core values are shared by all members of the nursing profession. Nurses typically acquire these values through the process of socialization to the profession. According to the American Association of Colleges of Nursing (AACN, 2008), five values that are essential for all professional nurses are altruism, autonomy, human dignity, integrity, and social justice:

- **Altruism** is concern for the welfare and well-being of others. In practice, altruism is reflected in the nurse's concern for the welfare of patients, other nurses, and other healthcare providers.
- **Autonomy** is the right to self-determination. Professional practice reflects autonomy when the nurse respects patients' rights to make decisions about their healthcare.
- **Human dignity** refers to the inherent worth and uniqueness of individuals and populations. The nurse who values and respects all patients and colleagues shows respect for human dignity.
- **Integrity** is acting in accordance with an appropriate code of ethics and accepted standards of practice. Integrity is reflected in professional practice when the nurse is honest and provides care based on an ethical framework that is accepted within the profession (e.g., the American Nurses Association Code of Ethics).
- **Social justice** refers to the upholding of justice, or what is fair, on a social scale. Nurses act in accordance with social justice by treating all patients equally without regard to economic status, ethnicity, age, gender, religion, citizenship, disability, or sexual orientation.

Some professional behaviors associated with these five essential values are outlined in **Box 44-1** ».

Clarifying Patients' Values

To plan effective care, nurses must also identify patients' values, because these values often influence and relate to particular health problems. For example, a patient with failing eyesight will probably place a high value on the ability to see, whereas a patient with chronic pain will likely place high value on comfort. When patients hold unclear or conflicting values that are detrimental to their health, the nurse should use values clarification as an intervention. Some behaviors that may indicate the need for clarification of a patient's health values are listed in **Table 44-1** ».

Nurses can help patients clarify their values through the use of the following seven-step process:

1. **List alternatives.** First, make sure the patient is aware of all alternative actions. A good way to start this conversation is by asking, "Are you considering other courses of action? If so, tell me about them."

Box 44–1

Professional Behaviors Associated with Core Nursing Values

Nurses embody the core values of their profession whenever they do the following:

- Demonstrate the professional standards of moral, ethical, and legal conduct.
- Assume accountability for personal and professional behaviors.
- Promote the image of nursing by modeling the values and articulating the knowledge, skills, and attitudes of the nursing profession.
- Demonstrate professionalism—including attention to appearance, demeanor, and respect for self and others—and professional boundaries with patients and families as well as among fellow caregivers.
- Demonstrate an appreciation of the history of and contemporary issues in nursing and their impact on current nursing practice.
- Reflect on their own beliefs and values as they relate to professional practice.
- Identify personal, professional, and environmental risks that impact personal and professional choices and behaviors.
- Inform the healthcare team of any personal biases on difficult healthcare decisions that may impact their ability to provide care.
- Recognize the impact of attitudes, values, and expectations on the care of the very young, frail older adults, and other vulnerable populations.
- Protect patient privacy and the confidentiality of patient records and other privileged communications.
- Access interprofessional and intraprofessional resources to resolve ethical and other practice dilemmas.
- Act to prevent unsafe, illegal, or unethical care practices.
- Articulate the value of pursuing practice excellence, lifelong learning, and professional engagement to foster professional growth and development.
- Recognize the relationship between personal health, self-renewal, and the ability to deliver sustained quality care.

Source: American Association of Colleges of Nursing. (2008). *The essentials of baccalaureate education for professional nursing practice* (p. 29). Washington, DC: Author. Used with permission.

2. **Examine possible consequences of choices.** Next, make sure the patient has thought about the potential results of each possible course of action. Some questions to aid in this effort include “What do you think you will gain from doing that?” and “What benefits do you foresee from doing that?”
3. **Freely choose a course of action.** To determine whether a patient chose freely, pose questions such as “Did you have any say in that decision?” or “Did you have a choice?”
4. **Feel good about the choice.** To determine how the patient views the choice, ask, “How do you feel about this decision (or action)?” Because some patients may not feel satisfied with their decision, a more sensitive question might be “Some people feel good after a decision is made, while others feel bad. How do you feel?”

5. **Affirm the choice.** Ask the patient, “How will you discuss this choice with others (family, friends, and so on)?”
6. **Act on the choice.** Find out whether the patient is prepared to act on the decision by asking for specifics about his or her plan of action.
7. **Act with a pattern.** To determine whether the patient consistently behaves in a certain way, ask, “How many times have you done that before?” or “Would you act that way again?”

When implementing this clarification process, the nurse should help the patient think each question through, but the nurse should not impose his or her personal values on the patient. In fact, the nurse should rarely, if ever, offer an opinion, even when the patient asks for it—and then only with great care or when the nurse is an expert in the content area. Each person’s situation is different, and what the nurse would choose in his or her own life might not be relevant to the patient’s circumstances. If the patient asks the nurse, “What would you have done in my situation?” the nurse should redirect the question back to the patient rather than answering from the nurse’s personal viewpoint.

TABLE 44–1 Patient Behaviors That May Indicate Unclear Values

Behavior	Example
Ignoring a health professional’s advice	A patient with heart disease who values hard work ignores advice to exercise regularly.
Inconsistent communication or behavior	A pregnant woman says she wants a healthy baby but continues to drink alcohol and smoke tobacco.
Numerous admissions to a health agency for the same problem	A man with obesity repeatedly seeks help for back pain but does not lose weight.
Confusion or uncertainty about which course of action to take	A woman wants to obtain a job so she can meet her financial obligations but also wants to stay at home to care for her ailing husband.

Concepts Related to Ethics

Ethical patient care encompasses more than managing difficult care decisions or facing the moral issues surrounding a patient. Ethical care also involves appropriate completion of common care tasks, including pain control; providing adequate patient teaching; demonstrating respect for patients from diverse backgrounds; advocating for the rights of all patients, regardless of their level of development or cognition; ensuring confidentiality; advocating for patients’ safety; and supporting patients’ right to self-determination.

Concepts Related to Ethics

CONCEPT	RELATIONSHIP TO ETHICS	NURSING IMPLICATIONS
Advocacy	<p>Nurses must ensure patients receive sufficient information on which to base consent for care and related treatment.</p> <p>Nurses must also provide an environment that allows patients to make their own care decisions, as appropriate.</p>	<ul style="list-style-type: none"> ■ Make sure medical staff clearly discuss all interventions with the patient and provide information sufficient to ensure informed consent. ■ Discuss the plan of care with the patient and allow self-determination as appropriate (e.g., allow the patient to choose which medication dosage to try first). ■ Recognize the patient's right to refuse treatment and procedures.
Cognition and Development	<p>Patients with developmental limitations or disorders that affect their cognitive function may not be able to understand the implications of a situation or may make important decisions on their own without adequate support. Nurses have a duty to advocate on behalf of these patients, not only to help preserve their rights to autonomy, dignity, and respect, but also to help ensure that they do not become victims of abuse.</p>	<ul style="list-style-type: none"> ■ Understand state laws regarding the determination of incapacity and state and federal laws protecting the rights of disabled individuals. ■ Assume that patients have the capacity to make their own decisions unless there is clear evidence or documentation otherwise. ■ Understand the concept of guardianship, including when patients should be under the care of a guardian, as well as what limitations are placed on the guardian role. ■ Advocate for patients with limited cognition or intellectual ability when their rights appear to be in jeopardy or when others make decisions that may not be in their best interest.
Comfort	<p>Chronic pain is a common problem in the United States, but many affected individuals lack access to healthcare resources that can help them adequately control their pain. Other people with chronic pain consume excessive amounts of healthcare resources, causing shortages of these resources for other patients. Both sides of this situation raise ethical issues related to resource allocation, social justice, and what constitutes an acceptable outcome of care for patients with chronic pain. The nurse also has an ethical obligation to collaborate with the patient and care team to manage the patient's pain in a way that minimizes the likelihood of medication abuse.</p>	<ul style="list-style-type: none"> ■ Become educated about chronic pain. ■ Engage with patients to develop a deeper understanding of the duration and severity of their pain. ■ Refer patients to pain management specialists as appropriate. ■ Help patients develop realistic expectations about the degree to which their pain can be alleviated. ■ Ask for support from supervisors or peers when advocating for appropriate patient care. ■ Recognize and set aside personal assumptions or biases surrounding narcotic use. ■ Educate patients about and monitor for signs of painkiller abuse or addiction.
Communication	<p>Nurses are obligated to ensure the confidentiality of patient information during all care and in all care areas.</p>	<ul style="list-style-type: none"> ■ Ensure that access to patient information, such as online charting, is made available only to appropriate staff members. ■ Do not discuss a particular patient's situation with individuals who do not require this information as part of their job. ■ Observe all laws and institutional policies related to the confidentiality of patient information. ■ Inform the patient of policies and procedures that ensure confidentiality.
Legal Issues	<p>The Health Insurance Portability and Accountability Act (HIPAA) sets forth specific guidelines nurses must follow to protect patient information. Thus, preserving patient confidentiality is both an ethical duty and a legal obligation. Nurses also help to protect patients' right to self-determination by ensuring that advance directives are in place and followed correctly.</p>	<ul style="list-style-type: none"> ■ Understand what constitutes "protected health information" under HIPAA's Privacy Rule. ■ Take appropriate measures to preserve the confidentiality of protected health information. ■ Discuss different types of advance directives with patients before surgery and other procedures that carry a degree of risk. ■ When patients are incapacitated, ensure that any advance directives are followed correctly and in the manner the patient intended.

Concepts Related to *(continued)*

CONCEPT	RELATIONSHIP TO ETHICS	NURSING IMPLICATIONS
Teaching and Learning	Because they are now sent home earlier than in years past, patients often require detailed instructions regarding critical aspects of their own care. The nurse has a professional obligation and an ethical duty to provide this teaching and to ensure that the patient understands the teaching and can properly carry out any self-care tasks.	<ul style="list-style-type: none"> ■ Assess the patient's learning needs and abilities at the time of the initial encounter (whether in the ED, operative unit, acute care unit, clinic, or home). ■ Plan teaching interventions for the patient using appropriate methods and materials. ■ Recognize and set aside personal assumptions and values about the best ways to receive care information. ■ Follow up to ensure that the patient understands the teaching and that the teaching furthers the patient's sense of autonomy and self-determination.

American society is increasingly diverse, and this diversity has ethical implications for nursing practice. In particular, nurses have a responsibility to show respect to all of their patients, regardless of gender, race, ethnicity, religion, disability, sexual orientation, or any other personal characteristic. This obligation is clearly stated in the American Nurses Association's *Code of Ethics for Nurses with Interpretive Statements* (ANA, 2015a), which declares that nurses must respect the inherent dignity and rights of all patients, provide nursing services without bias or prejudice, work to eliminate disparities in care, and consider each patient's "culture, value systems, religious or spiritual beliefs, lifestyle, social support system, sexual orientation or gender expression, and primary language" when creating a plan of care (p. 1). In addition, ethical standards require that nurses neither project their own cultural preferences onto their patients nor view patients' cultural beliefs as inferior to or less valid than their own. For additional discussion of

the intersection between diversity and nursing ethics, see the Focus on Diversity and Culture feature.

Of course, nurses have a responsibility to advocate for all patients, not just those who differ in terms of culture, cognition, or development. Part of the advocate role involves making sure that each patient's right to confidentiality is preserved. This requires the nurse to observe all laws and institutional policies meant to protect patient information. Ensuring confidentiality also means that the nurse must exercise good professional judgment when communicating with others, including the patient's family and other members of the healthcare team. Similarly, nurses must advocate for every patient's right to self-determination, including the right to establish advance directives and have them carried out according to the patient's wishes. Some, but not all, of the concepts integral to ethics are outlined in the Concepts Related to Ethics feature. They are listed in alphabetical order.

Focus on Diversity and Culture

Religion, Ethics, and Nursing Practice

For many people, including many nurses, the concepts of religion and ethics are intimately intertwined. For example, an individual's religion often informs his or her beliefs about social justice, end-of-life issues, the nature of suffering, and the very meaning of human existence, to list just a few topics. When nurses encounter patients whose religious beliefs differ from their own, ethical conflicts may arise. Nurses can help to minimize the likelihood of such conflicts by keeping several principles in mind:

- First, nurses should seek to identify any ethical common ground that exists between themselves and their patients. Despite the significant differences that exist between the world's many religions, most belief systems place some value on helping the less fortunate, taking responsibility for one's actions, and treating others as you wish to be treated, among other things. In many situations in which an ethical conflict initially seems to exist, the nurse and patient can reach a shared understanding of which course of action is most ethical by looking at the situation through the lens of these common beliefs.
- Nurses should also recognize that not every person adheres to all of the beliefs typically associated with the person's religious background. For example, although official Roman Catholic teaching forbids the use of birth control and sets specific guidelines regarding end-of-life care, many Catholics find it morally and ethically acceptable to disregard these teachings. A thorough assessment of each patient's unique belief system can help the nurse to avoid assuming that religion-based ethical conflicts exist when they do not.
- Above all, nurses must remember that they have an ethical obligation to respect the patient's beliefs and right to autonomy throughout the care process. The nurse should honor the patient's beliefs and decisions unless the patient's choices will cause the nurse to act in a way that violates his or her own deeply held beliefs. In such cases, the nurse should seek guidance from supervisors, ethics committees, and other resources as appropriate.

Case Study » Part 1

June D'Angelo, a 49-year-old woman of Italian descent, presents to the emergency department (ED) late at night complaining of a severe migraine headache. Her vital signs show that her blood pressure is elevated at 210/104 mmHg. The ED physician discusses her history and finds that Ms. D'Angelo has been in the ED five times in the past year for the same problem. Ms. D'Angelo was prescribed a daily blood pressure medication by her primary physician 3 weeks earlier; however, she says she is not taking the medication and has not even filled the prescription but instead has decided to take daily walks to manage her blood pressure.

The ED physician asks Ms. D'Angelo how recently her headaches began and how long each one typically lasts. Ms. D'Angelo sighs and said that her migraines mostly never end and have gotten worse in the past 24 hours. When the physician leaves the bedside to call Ms. D'Angelo's healthcare provider, he gives orders to the nurse for IV blood pressure medication for Ms. D'Angelo. As the nurse prepares to provide the IV medication, Ms. D'Angelo says, "I'll take this medication, because I know it will make the pain go away. But I'm not taking that daily medication." The nurse then speaks with Ms. D'Angelo to complete a brief nursing assessment to determine why Ms. D'Angelo is reluctant to take daily blood pressure medication. Findings from the assessment indicate that Ms. D'Angelo relies on the ED to manage her pain and does not follow her primary healthcare provider's instructions, and that she feels exercise should be enough to manage her high blood pressure.

Critical Thinking Questions

1. What ethical issue is the nurse facing as she assesses this patient with frequent ED admissions?
2. What topics should be included in patient teaching for Ms. D'Angelo?
3. What further information should the nurse assess before planning patient teaching?
4. How can the nurse assist Ms. D'Angelo in planning how to manage her symptoms better?
5. Who should be involved in this patient's discharge planning and self-care? Explain.

Nursing Codes of Ethics

Ethical standards and behaviors are at the core of nursing practice. As a result, the nursing profession has developed formal codes of ethics to guide nurses in their work with patients and other healthcare professionals. A **code of ethics** is both a general guide for a profession's membership and a social contract with the public that the profession serves.

The Nightingale Pledge is considered the first code of nursing ethics used in the United States. Written in 1893 by Lystra Gretter, principal of the Farrant Training School for Nurses in Detroit, and patterned after the Hippocratic Oath for medicine, the Nightingale Pledge was named in honor of Florence Nightingale. The Nightingale Pledge is still used at many nursing schools' graduation ceremonies. It reads as follows:

I solemnly pledge myself before God and in the presence of this assembly to pass my life in purity and to practice my profession faithfully. I will abstain from whatever is deleterious and mischievous, and will not take or knowingly administer any

harmful drug. I will do all in my power to elevate the standard of my profession, and will hold in confidence all personal matters committed to my keeping, and all family affairs coming to my knowledge in the practice of my profession. With loyalty will I endeavor to aid the physician in his work and devote myself to the welfare of those committed to my care (Gretter, 1910).

Over the years, the Nightingale Pledge was modernized, then largely replaced by longer, more comprehensive codes of ethics. Today, the nursing profession depends primarily on two major codes of ethics: the International Council of Nurses (ICN) *Code of Ethics* and the American Nurses Association (ANA) *Code of Ethics for Nurses*. These codes were initially adopted in the early 1950s and have undergone changes to reflect social and technologic change. The ICN code was most recently updated in 2012. The current version is presented in **Box 44-2** ».

The latest version of the ANA *Code of Ethics for Nurses with Interpretive Statements* was released in 2015, after a four-year period of input and revision (ANA, 2015b). Within the United States, this code serves as a statement of nurses' ethical obligations and duties, as the profession's nonnegotiable ethical standard, and as the nursing profession's statement of commitment to society. All nurses should regularly refer to the ANA *Code of Ethics* to direct how they perform their duties in daily practice. The nine provisions of the ANA *Code of Ethics* appear in **Box 44-3** ».

Using codes of ethics in everyday practice requires seeking knowledge and understanding of the patient's needs and preferences (whether the patient is a single individual, a family, a group, a community, or a population) as well as self-awareness on the part of the nurse. The following questions can help nurses apply Provision 2 to ethical problems (Kangasniemi & Haho, 2012; Lachman, 2012):

- What do I know about this patient's situation?
- What do I know about the patient's values and moral preferences?
- What assumptions am I making that require more data to clarify?
- What are my own feelings (and values) about the situation? How might they be influencing how I view and respond to the situation?
- Are my own values in conflict with those of the patient?
- What else do I need to know about this case, and where can I obtain this information?
- What can I never know about this case?
- Given my primary obligation to the patient, what should I do to be ethical?

SAFETY ALERT Although nurses have a duty to protect all research participants, they must pay special attention to research involving vulnerable populations, such as children, pregnant women, prisoners, older adults, and people with cognitive impairments. Because members of these groups often have limited autonomy, they are especially vulnerable to coercion, undue influence, and abuse.

Box 44–2

The ICN Code of Ethics

1. Nurses and people
 - The nurse's primary professional responsibility is to people requiring nursing care.
 - In providing care, the nurse promotes an environment in which the human rights, values, customs and spiritual beliefs of the individual, family and community are respected.
 - The nurse ensures that the individual receives accurate, sufficient and timely information in a culturally appropriate manner on which to base consent for care and related treatment.
 - The nurse holds in confidence personal information and uses judgement in sharing this information.
 - The nurse shares with society the responsibility for initiating and supporting action to meet the health and social needs of the public, in particular those of vulnerable populations.
 - The nurse advocates for equity and social justice in resource allocation, access to health care and other social and economic services.
 - The nurse demonstrates professional values such as respectfulness, responsiveness, compassion, trustworthiness and integrity.
2. Nurses and practice
 - The nurse carries personal responsibility and accountability for nursing practice, and for maintaining competence by continual learning.
 - The nurse maintains a standard of personal health such that the ability to provide care is not compromised.
 - The nurse uses judgement regarding individual competence when accepting and delegating responsibility.
 - The nurse at all times maintains standards of personal conduct which reflect well on the profession and enhance its image and public confidence.
3. Nurses and the profession
 - The nurse, in providing care, ensures that use of technology and scientific advances is compatible with the safety, dignity and rights of people.
 - The nurse strives to foster and maintain a practice culture promoting ethical behaviour and open dialogue.
3. Nurses and the profession
 - The nurse assumes the major role in determining and implementing acceptable standards of clinical nursing practice, management, research and education.
 - The nurse is active in developing a core of research-based professional knowledge that supports evidence-based practice.
 - The nurse is active in developing and sustaining a core of professional values.
 - The nurse, acting through the professional organisation, participates in creating a positive practice environment and maintaining safe, equitable social and economic working conditions in nursing.
 - The nurse practices to sustain and protect the natural environment and is aware of its consequences on health.
 - The nurse contributes to an ethical organisational environment and challenges unethical practices and settings.
4. Nurses and co-workers
 - The nurse sustains a collaborative and respectful relationship with co-workers in nursing and other fields.
 - The nurse takes appropriate action to safeguard individuals, families and communities when their health is endangered by a co-worker or any other person.
 - The nurse takes appropriate action to support and guide co-workers to advance ethical conduct.

Box 44–3

The Provisions of the Code of Ethics for Nurses

- Provision 1.** The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.
- Provision 2.** The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population.
- Provision 3.** The nurse promotes, advocates for, and protects the rights, health, and safety of the patient.
- Provision 4.** The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.
- Provision 5.** The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.

Provision 6. The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality health care.

Provision 7. The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.

Provision 8. The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.

Provision 9. The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice into nursing and health policy.

Case Study » Part 2

After June D'Angelo receives her IV hypertension medication, she tells both her nurse and the physician that she feels much better, "just like last time." The ED physician asks the nurse to stay by the bedside as he tells Ms. D'Angelo about his phone conversation with her primary healthcare provider. During the call, the physician learned about Ms. D'Angelo's tendency to miss appointments with her primary provider and her failure to fill prescriptions. The ED physician suggests that the best way for Ms. D'Angelo to avoid further ED visits is for her to collaborate with her primary provider to control her hypertension and headaches. The nurse then asks Ms. D'Angelo what barriers are preventing her from trusting and collaborating with her provider. Ms. D'Angelo says that her main worry is that her blood pressure will be so high that she will miss work and need to see the physician too many times. The physician tells Ms. D'Angelo that he wants her to take responsibility for her own well-being, then asks a clinical nurse specialist to meet with Ms. D'Angelo to prepare an outpatient blood pressure management plan. Before Ms. D'Angelo is discharged from the ED, she is given a calendar listing her next two outpatient appointments and a prescription for a new blood pressure medication.

Critical Thinking Questions

1. Why was it important for the nurse to ask Ms. D'Angelo about barriers to outpatient care management?
2. How did the discussion at Ms. D'Angelo's bedside maximize her well-being?
3. How did the nurse and clinical nurse specialist assist the patient's need for autonomy?
4. Analyze how the bedside discussion was an example of collaborative practice in which nurses function effectively in cooperation with other healthcare professionals.

Principles and Practices of Ethical Decision Making

An individual's personal, community, and professional values ultimately inform his or her decision-making processes. In turn, each profession has its own set of values or principles that shape how its members approach ethical decisions. For professional nurses, the four primary principles that shape ethical decision making are autonomy, beneficence, justice, and veracity.

Autonomy

Autonomy is the right to self-determination. Individuals have "inward autonomy" if they have the ability to make choices; they have "outward autonomy" if their choices are not limited or imposed by others. In the context of nursing, autonomy means that patients have the right to determine their own care. The nurse honors this principle by respecting the patient's decisions even if those decisions are in conflict with what the nurse believes is in the patient's best interest. In a healthcare setting, the principle of autonomy is violated, for example, when a nurse disregards patients' subjective accounts of their symptoms (e.g., pain). Furthermore, respect for autonomy means that no

individual should be treated as an impersonal source of knowledge or training.

Beneficence

Beneficence requires that "the actions one takes should promote good; it is the basic obligation to assist others" (Guido, 2014, p. 36). For nurses, this obligation extends to include the related principle of **nonmaleficence**, which requires that nurses do no harm and instead safeguard their patients. Intentional harm is clearly not in keeping with this principle, but there can also be risk of harm in performing nursing interventions that are intended for good. Nonmaleficence does *not* mean that the nurse performs only actions that carry no risk to the patient. After all, many actions, such as administering medications, carry some degree of risk. In most cases, the risk of harm is weighed against the potential for benefit. Also, before the action is taken, the patient is given information about the potential benefits and risks, and the patient decides whether to accept the treatment. Consider the example of administering pain medication to a patient after an operation. The risks of discomfort from the injection and side effects from the medication are typically outweighed by the goal of relieving the patient's suffering. Unintentional harm occurs when a risk could not have been anticipated. For instance, while catching a patient who is falling, a nurse might grip the patient tightly enough to cause bruises to the patient's arm.

Justice

Nurses must uphold the principle of justice in their practice. Here, **justice** means treating all patients fairly and in accordance with honor, standards, or law. This principle most commonly arises when decisions about the allocation of scarce resources must be made. For example, suppose that a nurse who is making home visits finds one patient tearful and depressed. The nurse knows that she could help this patient by staying for 30 more minutes to talk. However, that would take time from the nurse's next patient, who has diabetes and needs a great deal of teaching and observation. The nurse must weigh the facts carefully in order to divide her time justly among her patients.

Veracity

Individuals who always tell the truth reflect the principle of **veracity** (Guido, 2014, p. 37). Veracity can be a particularly challenging principle for the nurse, who may be faced with providing a patient with complete information about his or her illness even though family members or significant others want the information withheld. Veracity is the principle that underlies the need for healthcare providers to give patients complete information before obtaining informed consent for any procedure. Veracity is also one of several principles behind timely and accurate documentation of nursing interventions.

Applying the Principles

The ultimate goal of the ethical reasoning process should be to arrive at a decision that is in the patient's best interest and

Box 44–4

Examples of Nurses' Obligations When Making Ethical Decisions

The nurse has an obligation to:

- Maximize the patient's well-being.
- Balance the patient's need for autonomy with family members' responsibilities for the patient's well-being.
- Support each family member and enhance the family support system.
- Carry out hospital, clinic, or agency policies.
- Protect other patients' well-being.
- Protect his or her own standards of care.

at the same time preserves the integrity of all individuals involved. Nurses have ethical obligations to their patients, to themselves, to the agency that employs them, and to primary care providers. Therefore, nurses must weigh competing factors when making ethical decisions. Responsible ethical decision making is rational and systematic. It should be based on the ethical principles and codes described throughout this module and not on emotions, intuition, fixed policies, or precedent (i.e., an earlier similar occurrence). **Box 44–4** » provides some examples of the obligations nurses must take into account.

Although the nurse's input is important, several individuals are usually involved in ethical decision making. Frequently, the patient, family, and other members of the healthcare team all work together in reaching a decision (see **Figure 44–1** »). Sometimes families will seek help from a spiritual advisor, such as a minister, priest, imam, rabbi, or other trusted individual. Therefore, collaboration, communication, and compromise are important skills that contribute not only to successful nursing practice, but also to a more ethical practice environment. Stress management is another valuable skill for the professional nurse. In many

Figure 44–1 » When there is a need for ethical decisions with regard to patient advocacy, the patient, family, and healthcare team contribute to the final outcome.

cases, the nurse may feel torn among his or her obligations to patient, family, and employer. Also, what is in the patient's best interest might be contrary to the nurse's personal belief system. To help control their stress levels and allow for expression of their feelings, nurses who work in settings in which ethical issues frequently arise should establish support systems such as team conferences and use of counseling professionals.

Of course, many nursing problems are not moral or ethical problems at all; they are simply questions of good nursing practice. Therefore, an important first step in ethical decision making is to determine whether a moral dilemma actually exists. Generally speaking, a moral dilemma is said to exist when the following criteria are satisfied:

- A difficult choice exists between actions that conflict with the needs of one or more individuals.
- There are moral principles or frameworks that can be used to provide some justification for one or more of the actions.
- The choice is guided by a process of weighing reasons.
- The decision is freely and consciously chosen.
- The choice is affected by personal feelings and by the particular context of the situation.

When these conditions are met, the nurse should proceed with the ethical reasoning process. When they are not, the nurse should refer to professional standards of practice for guidance in determining the appropriate course of action.

Strategies to Enhance Ethical Decisions and Practice

Even when nurses do their best to adhere to the principles of their profession and engage in sound decision making, they still occasionally encounter organizational and social constraints that can hinder the ethical practice of nursing and create moral distress. Several strategies can help them overcome these hurdles. In particular, nurses can do the following:

- Become aware of their own values and the ethical aspects of nursing.
- Be familiar with the nursing codes of ethics.
- Seek continuing education opportunities to stay knowledgeable about ethical issues in nursing.
- Respect the values, opinions, and responsibilities of other healthcare professionals that may be different from their own.
- Participate in or establish ethics rounds. Ethics rounds use hypothetical or real cases that focus on the ethical dimensions of patient care rather than clinical diagnosis and treatment.
- Serve on institutional ethics committees.
- Strive for collaborative practice in which nurses function effectively in cooperation with other healthcare professionals.

One resource that is available to help nurses maintain current, evidence-based ethical practice is the National Guideline Clearinghouse (NGC). Maintained by the Agency for Healthcare Research and Quality (AHRQ) within the Department of Health and Human Services, the NGC provides an index to more than 2000 guidelines for evidence-based practice on a number of health issues, including ethical issues. For example, the Hartford Institute of Geriatric Nursing has developed a number of evidence-based nursing protocols for working with older patients. These protocols address topics such as advance directives, working with older adults with dementia, and discussing sexual health with older adults (NGC, 2017). Guidelines criteria were revised in 2013, and the Advanced Search page on the NGC website allows users to easily locate any of the nearly 500 guidelines that satisfy these new criteria.

» **Stay Current:** Visit the National Guideline Clearinghouse online at www.guideline.gov

Ethical dilemmas can occur in the normal provision of care. The frequency of ethical dilemmas was reported as being negatively correlated with the level of nursing skills (Dekeyser Ganz & Berkovitz, 2012). In effect, this study found that the less experienced nurses are, the more likely they are to encounter ethical dilemmas. Thus, for many nurses, seeking advice from a mentor or a more experienced peer is a strategy that can facilitate effective solutions and approaches to perceived ethical challenges.

Another strategy that hospitals and other organizations have used to enhance ethical decision making is to implement a multidisciplinary ethics committee. In fact, the ethical standards of The Joint Commission (2013a) mandate that healthcare institutions provide ethics committees or similar

structures to write guidelines and policies and to provide education, counseling, and support on ethical issues. These multidisciplinary committees, which include nurses, physicians, and hospital administrators, can be asked to review a case and provide guidance to a competent patient, to an incompetent patient's family, or to healthcare providers. Ethics committees provide a forum in which diverse views can be expressed, support is provided for caregivers, and the institution's legal risks can be reduced. (For additional information on this topic, see the module on Quality Improvement.)

Case Study » Part 3

Reread Parts 1 and 2 of the case study. Before the end of the shift, another staff member in the ED asks the nurse to pick up the phone. As soon as she says hello, a woman asks her, "Did June D'Angelo come to your department earlier today?" The nurse immediately realizes that this situation will become a HIPAA issue if she does not manage it carefully and correctly. She asks the woman, "Who is calling, please?" The woman groans loudly and says, "This is Mrs. Jones. I am June's supervisor where she works, and I need to know if she was there today." The nurse answers, "Mrs. Jones, I am sorry, but due to privacy rules, we cannot discuss any patient information or names on the phone and cannot confirm whether any patient was or was not in our department." Mrs. Jones becomes upset and states, "Then how can I know what is going on? June missed her shift today!" The nurse remains calm and replies, "My best suggestion is that you contact your employee directly yourself." At that point, Mrs. Jones hangs up.

Critical Thinking Questions

1. How did the nurse realize that this was a possible HIPAA issue?
2. What privacy and confidentiality rules and ethical guidelines was the nurse following?
3. Do you think the nurse managed the call correctly?

REVIEW The Concept of Ethics

RELATE Link the Concepts

Linking the concept of ethics with the concept of addiction:

1. How does substance abuse affect people's ability to make ethical decisions based on their personal values and beliefs?
2. What parts of the ANA *Code of Ethics for Nurses* address impaired nurses?

Linking the concept of ethics with the concept of reproduction:

3. What are your personal beliefs regarding fertility treatments? How would you feel about a patient who has conceived multiple fetuses through fertility treatments and now wants to have selective reduction to reduce the number of fetuses she will carry to term?
4. As a nurse, what are your responsibilities to a teenager who is seeking information on birth control methods?

REFLECT Apply Your Knowledge

Keith Morgan, a 46-year-old man, fell and broke his leg several weeks ago. He is now receiving home healthcare. You are a home health nurse case manager, and you go to Mr. Morgan's home to assess his ability to ambulate. When you arrive, Mr. Morgan is alert and oriented but continues to report a high pain level. During your assessment, he tells you that Tylenol just isn't effective in controlling his pain. When you ask him about the effect of the narcotic that has been prescribed and documented as given by his primary nurse, Mr. Morgan tells you that the nurse told him all he needed was Tylenol and that he has not taken any other pain medication.

1. How should you respond to Mr. Morgan?
2. What is your legal responsibility in this scenario? What is your ethical responsibility? What actions do you need to take?

Exemplar 44.A Morality

Exemplar Learning Outcomes

44.A Analyze morality as it relates to ethics.

- Explain the development of morality.
- Explain how moral theories can be used as a framework for examining ethical dilemmas.
- List three types of moral theories.
- Summarize moral principles.

Overview

Morality typically refers to an individual's private standards of what is right and wrong, not only in terms of conduct, but also in terms of character and attitude. When the members of a group share many of these standards, morals may serve as the basis for the group's ethics, that is, its system of standards governing behaviors and relationships. Morals also help shape the laws of a society, although some actions may be legal but not moral, while others may be moral but illegal.

Just as people tend to confuse morality and ethics, they also tend to wrongly conflate morality and spirituality. Certainly, an individual's spiritual and/or religious beliefs may shape his or her ideas regarding right and wrong. For example, a person may be morally opposed to blood transfusions, sterilization, abortion, contraception, or any number of medical interventions because his or her religion forbids these things. However, people need not hold any spiritual beliefs whatsoever to cultivate a clear sense of morality. (For more information, refer to the module on Spirituality.)

Theories of Morality and Moral Development

Because morality intersects with so many of humankind's "big questions" about life and death, it has long been a topic of philosophical interest and debate. Much of this interest has revolved around the theoretical basis of morality, while some of it has focused on formulating a clearer picture of the process by which a person's moral standards emerge.

Moral Frameworks

Moral theories provide different frameworks through which nurses can view and clarify patient care situations. Nurses can use moral theories in developing explanations for their ethical decisions and actions and in discussing problem situations with others. Three types of moral theories are widely used, and they can be differentiated by their emphasis on (a) consequences, (b) principles and duties, or (c) relationships:

- **Consequence-based (teleologic) theories** look to the outcomes of an action in judging whether that action is

Exemplar Key Terms

 Utilitarianism, 2739
 Utility, 2739

right or wrong; these theories generally focus on issues of fairness. **Utilitarianism**, one form of consequentialist theory, views a moral act as one that brings the most good and the least harm for the greatest number of people; this is called the principle of **utility**. A utilitarian approach is often used in making decisions about the funding and delivery of healthcare.

- **Principles-based (deontologic) theories** involve logical and formal processes and emphasize individual rights, duties, and obligations. With these theories, the morality of an action is determined not by its consequences, but by whether the action is done according to an impartial, objective principle. For example, following the rule "Do not lie," a nurse might believe that he or she should tell the truth to a dying patient, even though the family has given instructions not to do so. There are many deontologic theories; each justifies the rules of acceptable behavior differently.
- **Relationship-based (caring) theories** stress courage, generosity, commitment, and the need to nurture and maintain relationships. Unlike consequence-based and principles-based theories, which frame problems in terms of justice (fairness) and formal reasoning, relationship-based theories judge actions according to a perspective of caring and responsibility. Whereas principles-based theories stress individual rights, relationship-based theories promote the common good or the welfare of the group.

A moral framework guides moral decisions, but it does not determine the outcome. For example, imagine a situation in which a frail older patient has made it clear that he does not want further surgery but his family and surgeon insist otherwise. Three nurses have decided that they will not help with preparations for surgery and that they will work through proper channels to try to prevent it. Using consequence-based reasoning, Nurse A thinks, "Surgery will cause the patient more suffering. He probably will not survive it anyway, and his family may even feel guilty later." Using principles-based reasoning, Nurse B thinks, "This violates the principle of autonomy. The patient has a right to decide what happens to his own body." Using relationship-based reasoning, Nurse C thinks, "My relationship with this patient commits me to

protecting him and meeting his needs, and I feel such compassion for him. I must try to help the family understand that he needs their support.” Each of these different perspectives is based on the individual nurse’s moral framework.

Moral Development

Ethical decisions require individuals to think and reason. Reasoning is a cognitive function and is, therefore, developmental. **Moral development** is the process of learning to tell the difference between right and wrong and of learning what ought and ought not to be done. This process is complex, beginning in childhood and continuing throughout life.

Theories of moral development attempt to answer questions such as “How does an individual become moral?” and “What factors influence the way an individual behaves in a situation involving a question of morals?” Two well-known theorists of moral development are Lawrence Kohlberg and Carol Gilligan. Kohlberg’s theory emphasizes rights and formal reasoning; Gilligan’s theory emphasizes care and responsibility, although it points out that individuals use the concepts of both theorists in their moral reasoning. (For a full discussion of these two theories, see the module on Development.)

Moral Principles of Professional Nursing

Moral principles are statements about broad, general, philosophical concepts such as autonomy and justice. They provide the foundation for **moral rules**, which are specific prescriptions for actions. For example, the rule “People should not lie” is based on the moral principle of respect for individuals (autonomy). Principles are useful in ethical discussions because even if individuals disagree about which action is right in a situation, they may be able to agree on the principles that apply. Such an agreement can serve as the basis for a solution that is acceptable to all parties. For example, most individuals would agree to the principle that nurses are obligated to respect their patients, even if they disagree about whether the nurse should deceive a particular patient about his or her prognosis.

Like many professions, nursing is shaped by a set of guiding moral principles that shape how their members act. For nurses, the most important moral principles are autonomy, nonmaleficence, beneficence, justice, fidelity, veracity, responsibility, and accountability. Autonomy, beneficence, nonmaleficence, justice, and veracity were discussed earlier in this module.

Fidelity

Fidelity means being faithful to agreements and promises. By virtue of their standing as professional caregivers, nurses have responsibilities to patients, employers, government, and society, as well as to themselves. Nurses often make promises such as “I’ll be right back with your pain medication” or “I’ll find out for you.” Patients take such promises seriously, and so should nurses, because doing so is central to the principle of fidelity.

Accountability and Responsibility

Nurses must also have professional accountability and responsibility. **Accountability** involves being answerable for the outcomes of a task or assignment. Nurses are accountable for their

own actions and behaviors, but they may also be accountable for the actions of others, such as subordinates or trainees. **Responsibility** is the specific obligation associated with the performance of duties of a particular role, and it belongs to the individual performing the duties. Thus, the ethical nurse is able to explain the rationale behind every action and recognizes the standards to which he or she will be held. (For more information, see the module on Accountability.)

NURSING PROCESS

Morality shapes the profession of nursing in many different ways. Not only do certain moral principles drive nursing theory, practice, and decision making, but they also serve as the foundation for the professional codes of ethics described earlier in this module. Nonetheless, unethical or immoral behavior still occurs among nurses. Although only a very few individuals in the profession exhibit this behavior, all nurses must be able to identify, discourage, and report it. In fact, failure to report certain forms of immoral behavior by another healthcare professional is a violation of the ANA *Code of Ethics for Nurses* and the nurse–patient relationship.

SAFETY ALERT Nurses have both an ethical and a legal responsibility to report certain forms of abuse to the appropriate authorities. Depending on the state in which a nurse practices, mandatory reporting laws may include known and/or suspected child abuse and neglect; elder abuse and neglect; and/or domestic violence. Nurses must also take action to ensure the safety of suspected victims of abuse and neglect.

To guard against questionable and unethical practices, nurses must have a thorough understanding of their own morality and what constitutes right and wrong for them as individuals. They must also have a thorough understanding of their professional code of ethics and be able to identify when the ethics of another professional or agency are contrary to the *Code of Ethics for Nurses*. Furthermore, nurses must recognize that they will encounter patients at various stages of moral development, patients with questionable or confusing morals, and patients who are immoral. Nursing ethics and professional codes of conduct require nurses to deliver high-quality, professional care to all patients, regardless of the patients’ morality. This can sometimes challenge even the most professional, experienced nurse. Examples of such challenges include the following:

- A patient with HIV is transferred to the critical care unit (CCU) of a hospital from the prison infirmary. The patient is paraplegic with no ability to move his legs. He is serving a life sentence in prison for repeated child molestation and rape.
- A young woman comes to the local free health clinic with her boyfriend to get a pregnancy test. The test is positive. The boyfriend immediately starts talking to her about how she’ll have to get an abortion.
- An older woman is brought to the emergency department by a friend who came to visit and found the woman lying in her own feces. She is weak and dehydrated. The friend says that the woman lives with her son and his wife.

To care for patients such as these, nurses must have an awareness of their own morality and ethics, a thorough understanding of the requirements they must follow under the professional code of ethics, and an understanding of the reporting requirements in their state and the procedures they must follow in their place of employment. Although a nurse's own personal beliefs, morality, and bias will influence how the nurse manages each situation, the nurse must ultimately remember his or her moral duty to provide the best possible care, no matter what the patient's morality or immorality may be. (See the Focus on Diversity and Culture feature for additional information.) The following sections take a closer look at how this duty comes into play during all stages of the nursing process.

Assessment

As with any patient, assessment of the patient who is immoral or who is exposed to immorality that involves abuse or mistreatment includes a nursing history and physical examination. Patients who are immoral may not be able or willing to participate in a trusting nurse–patient relationship and may not respond to attempts at therapeutic communication. In interviewing these patients, the nurse should maintain a calm, nonjudgmental manner and should ask open-ended questions in a matter-of-fact tone.

Diagnosis

Nursing diagnoses for an individual with moral dilemmas or distress or a patient with a family member or significant other with questionable morals will vary. For example, appropriate diagnoses in the scenarios mentioned earlier may include the following:

- The prisoner transferred to the CCU will have a number of diagnoses appropriate to his medical condition. In addition, the following nursing diagnoses may be appropriate:

Health Behavior, Risk Prone

Moral Distress

Noncompliance

Social Isolation.

(NANDA-I © 2014)

- The young woman who has just found out she is pregnant may be diagnosed with the following:

Self-Esteem, Situational Low, Risk for

Resilience, Impaired.

(NANDA-I © 2014)

- The older woman who was brought to the emergency department by a friend may be diagnosed with the following:

Family Processes, Interrupted

Powerlessness

Self-Esteem, Chronic Low

Social Isolation

Post-Trauma Syndrome.

(NANDA-I © 2014)

Focus on Diversity and Culture

Cultural Relativism

Cultural relativism is the idea that people's morals are deeply rooted in the beliefs and behaviors of their particular culture. According to this principle, even though a person's moral principles may conflict with our own, we should not automatically assume that these principles are indefensible or incorrect, because they likely make sense when viewed through the lens of that person's culture (Butts & Rich, 2013; Ellis & Hartley, 2012).

Cultural relativism was first popularized by anthropologists and other social researchers who wanted to describe and compare cultures in a systematic manner that was free from bias. This concept has become increasingly widespread throughout the field of nursing as theorists and practitioners alike place greater emphasis on cross-cultural care. Nursing's embrace of this concept has helped to bring about a care environment in which many patients feel more autonomous, more respected, and more valued. However, cultural relativism also creates moral and ethical dilemmas for the nurse.

Consider, for example, the practice of female genital mutilation (FGM), sometimes also known as "female circumcision." Although FGM involves physical mutilation of underage girls, some African and Middle Eastern cultures view it as morally acceptable and an important rite of passage into adulthood. Most Western cultures, however—as well as the United Nations and the World Health Organization (WHO)—regard FGM as a clear violation of the rights to autonomy, consent, and freedom from harm. Cultural practices that raise similar concerns include child marriage and severe limitations on the rights of females. When nurses encounter situations like these, they must carefully evaluate what course of action will produce greater benefit and/or lesser harm to the patient. In some cases, as in the case of FGM, the nurse's duty to preserve the patient's rights to self-determination, consent, and freedom from harm far outweigh the nurse's duty to honor the cultural preferences of the patient and the patient's family. The nurse may also be legally required to act in a certain way. Because situations like these are fraught with potential moral, ethical, and legal implications, it is always wise for the nurse to seek the counsel of a mentor or supervisor before deciding on an appropriate course of action.

Planning

Individuals with moral dilemmas or distress may find it difficult to participate in the planning process; they may even show disdain for it. The nurse may try to obtain cooperation by capitalizing on needs the patient presents during the assessment. For example, the nurse might say, "You said you didn't want to be in pain anymore, so we need to run these tests to find out what is causing your pain so that we can treat it," or "I know you don't like the food here, but remember we discussed that to feel better, you have to get appropriate nutrition." Although outcomes for these patients will vary widely, a few frequently appropriate outcomes include the following:

- The patient will participate appropriately as able in the therapeutic regimen.
- The patient will refrain from causing disruptions that affect other patients and staff.
- The patient will be appropriately supervised during caring interventions, diagnostic procedures, and other

activities. For example, a security staff member or member of law enforcement will be present during caring interventions for a patient with a history of assault.

Implementation

Caring for individuals with moral dilemmas or distress can be challenging, unpleasant, and time consuming. Interventions

that may be appropriate when working with these patients could include any of the following:

- Following procedures that ensure the safety of staff working with the patient and adding precautions or procedures as necessary to ensure safety of other patients and staff. Refer to the Safety Alert for additional information.

Nursing Care Plan

A Patient Presenting Morality Issues

Michael Dunham is a 50-year-old man with HIV who is also paraplegic. Mr. Dunham is admitted to the critical care unit (CCU) of the

local hospital from the prison infirmary, where he has been for more than a month.

ASSESSMENT	DIAGNOSES	PLANNING
<p>Mr. Dunham has a history of IV drug use and having sexual relations with female sex workers. He is admitted to the critical care unit of the local hospital from the prison infirmary, where he has been for more than a month. He is on oxygen by cannula. He is restrained to his bed. Almost every time members of the nursing staff work with him, he tries to spit on them in an effort to “give” them his disease. Upon arrival, the prison transport unit informs the head nurse that Mr. Dunham is serving a life sentence for molesting children and that he used his disability to trick preteen girls into coming close enough for him to handcuff them to his wheelchair so they could not escape his sexual abuse. Before releasing them, he would threaten to kill their parents if the girls told anyone what happened.</p> <p>Upon physical examination, the nurses working with Mr. Dunham find the following:</p> <ul style="list-style-type: none"> ■ Temperature 37.9°C oral (100.2°F), P 104 beats/min, R 32/min, BP 102/60 mmHg ■ Oxygen saturation 84%; breath sounds reveal coarse crackles in the left lower base ■ Mild cyanosis of nail beds and mucous membranes ■ Use of accessory muscles to breathe with intercostal and suprasternal retractions ■ Flaccid paralysis of lower extremities since the patient was 8 years old ■ ECG shows 2–3 premature ventricular contractions per minute ■ HIV positive with CD4 T-cell count of 64; CBC showed WBC of 9.8, elevated lymphocyte and low segs ■ Chest x-ray shows characteristic appearance of <i>Pneumocystis jirovecii</i> 	<ul style="list-style-type: none"> ■ <i>Moral Distress</i> ■ <i>Social Interaction, Impaired</i> ■ <i>Social Isolation</i> ■ <i>Gas Exchange, Impaired</i> ■ <i>Health Behavior, Risk-Prone</i> <p>(NANDA-I © 2014)</p>	<ul style="list-style-type: none"> ■ The patient will participate appropriately as able in the therapeutic regimen. ■ The patient will refrain from causing disruptions that affect other patients and staff. ■ The patient will be appropriately supervised during caring interventions, diagnostic procedures, and other activities. ■ Nursing staff will take appropriate precautions to prevent the spread of HIV.

IMPLEMENTATION

<ul style="list-style-type: none"> ■ A correctional officer or member of the hospital security staff will be present during any intervention in which removing the restraints is necessary. ■ Nurses will provide care in groups of two or more. ■ The patient will be offered counseling and a referral to the hospital chaplain. 	<ul style="list-style-type: none"> ■ The nurses caring for the patient will share their concerns with their supervisor or mentor. ■ The patient will be consulted and asked to give permission for all treatments and therapies. ■ Additional interventions will be used as warranted by medical condition and ordered by the attending physician.
---	---

EVALUATION

Mr. Dunham's condition continued to deteriorate, and he was placed on a mechanical ventilator. As it became increasingly difficult to meet	his oxygenation needs, he was given paralytics. Mr. Dunham ultimately died of cardiorespiratory failure.
--	--

CRITICAL THINKING

1. Does a nurse who is assigned to care for this patient have the option of requesting a different assignment on the basis of his or her feelings of revulsion, disgust, or anger at the patient's past history and behavior? Why or why not?
2. What interventions would be the most difficult for you to provide this patient? Explain your answer.
3. How would your moral beliefs regarding this patient's history and behavior affect your nursing care of the patient? Is it appropriate to reduce the quality of care you provide as a result? Explain your answer.

SAFETY ALERT When working with patients who are potentially dangerous, the nurse can help to ensure both personal safety and the safety of others by staying between the patient and the door and by notifying security to be present as necessary. Other appropriate measures may include restraining the patient, providing additional staff for interventions and procedures, and transporting the patient during times when hallways and other areas have the fewest people around.

- Encouraging patients to make informed decisions without pressure from others. In the earlier example of the young woman who learned that she was pregnant, her boyfriend was attempting to influence her decision. Although patients are free to seek advice from whomever they wish, the nurse must ensure that the patient makes a treatment decision free from coercion.

REVIEW Morality

RELATE Link the Concepts and Exemplars

Linking the exemplar of morality with the concept of development:

A mother brings her 13-year-old daughter to the gynecologist's office for the girl's first pelvic examination. The daughter is autistic and has a spoken vocabulary of fewer than 500 words. The mother tells the nurse that she wants to talk to the physician about getting her daughter's tubes tied or some other procedure that will keep her daughter from getting pregnant if anyone molests her.

1. How does the daughter's developmental level interfere with her ability to make autonomous decisions?
2. What ethical responsibilities do you have to the daughter in this situation?

Linking the exemplar of morality with the concept of comfort:

3. What moral or ethical issues are involved in patients' advance directives and do-not-resuscitate orders?
4. What are your feelings about the morality of do-not-resuscitate orders? How would you keep these feelings from influencing your discussions with a patient about do-not-resuscitate orders? Would your feelings change if the patient were a child or adolescent?

- Referring patients to spiritual leaders or mental health professionals as necessary. Consulting with these individuals may assist patients in the ethical decision-making process.

Evaluation

Treatment options that challenge individual morality and ethics, such as abortion and organ transplantation, often leave patients and family members second-guessing decisions after they have been made. Evaluation of patients who are faced with decisions that poses a challenge to their morality or of patients who lack morality should be based on the question "Is the patient satisfied that the best possible decision was made?" Nurses who work with patients in these situations should support autonomy; provide a listening, nonjudgmental ear; and continue to support the patient's decision after the conclusion of treatment.

REFLECT Apply Your Knowledge

The nurse on the day shift at an inpatient rehabilitation center is making her morning rounds when she finds a young woman awake and crying in her bed. The woman has bruises on her wrists and forearms that were not there when the nurse last saw the patient the previous afternoon. When the nurse asks the patient what happened, the patient responds only by shaking her head, and she pulls away when the nurse reaches out to comfort her. The nurse checks the visitor logs and confirms that the patient had no visitors the night before.

1. What are the priorities of care for the patient at this moment?
2. What steps should the nurse take to try to determine what happened to this patient?
3. How should the nurse document her findings, and with whom should the nurse share these findings?
4. Does the nurse have an obligation to report these findings? If so, to whom must she report them?

Exemplar 44.B Ethical Dilemmas

Exemplar Learning Outcomes

44.B Analyze dilemmas related to ethics.

- Propose solutions to ethical dilemmas based on an individual's problem and ethical principles.
- Analyze conflicts among nursing loyalties and obligations to patients, families, the multiprofessional team, and outside organizations.
- Critique the bioethical dilemmas that may arise during the care of patients and families.
- Explore the nurse's role in supporting patients' rights to information and counseling when making genetic testing decisions.

- Analyze the challenges and dilemmas patients and their families face when managing end-of-life care choices, advance directives, euthanasia, and the withdrawal of life support.
- Differentiate considerations related to ethical dilemmas for patients across the lifespan.

Withdrawing or withholding life-sustaining therapy (WWLST), 2749

Overview

An **ethical dilemma** exists when two or more rights, values, obligations, or responsibilities come into conflict. Conflict may arise between the nurse's personal values and those of another individual or the organization. Conflict may also develop between the nurse's principles and the need to achieve a desired outcome. Conflict may occur between two or more individuals or groups to whom the nurse has an obligation, such as the patient, a colleague, the nursing profession, the nurse's employer, or society (Dekeyser Ganz & Berkovitz, 2012; Lachman, 2012).

A number of factors contribute to ethical dilemmas. Rapidly changing technology and conflicting societal and cultural values are among the most important factors today. Technology pervades most aspects of our lives, and today's nurses have grown up in a tech-driven society. The result is new ethical concerns that didn't exist 10—or even 5—years ago. Social change is also altering the way in which patients and nurses approach routine aspects of the healthcare experience. Nurses must be prepared to handle dilemmas related to these key drivers of change.

Other factors that contribute to ethical dilemmas include the development of conflicting loyalties and obligations among nurses. Competing allegiances to patients, families, colleagues, employers, and self can make it difficult for the nurse to determine the most ethical course of action. In addition, increasing pressure to contain healthcare costs at the organizational level may result in situations that give rise to ethical dilemmas.

No matter the contributing factors, the nurse must recognize ethical dilemmas and take appropriate action. Some dilemmas affect the care patients receive, and the nurse must be prepared to inform the patient and other staff members of these issues. Other dilemmas may involve an individual's nursing practice. When such issues arise, the nurse must act in a manner consistent with the *ANA Code of Ethics for Nurses*. No matter the dilemma a nurse faces, recognizing and managing ethical challenges—and evaluating the outcomes of interventions taken—promote ethical practice.

Factors Contributing to Ethical Dilemmas

Ethical dilemmas arise in many situations and touch many areas of nursing practice. In spite of the diverse nature of these dilemmas, they often start with common contributing factors. Technologic change, social change, and conflicting loyalties are three such factors.

Technologic Changes

Technologic change creates new ethical dilemmas that did not previously exist. From the nursing perspective, there are two areas of technology that must be considered: medical technology and communications technology.

Medical technology has been changing nursing practice throughout the twentieth and twenty-first centuries as new treatments and devices revolutionize healthcare. Some devices, such as monitors, respirators, and feeding tubes, have been around for 50 to 100 years or more, but as they have become more sophisticated, they have presented more occasions for ethical dilemmas. For example, the decision of

whether to provide life-sustaining measures to an 800-gram premature infant would not exist without modern technology.

Devices are not the only medical technology to radically change the healthcare landscape. For example, organ transplantation is another procedure that has experienced great advances and is also subject to ongoing ethical debate. These debates focus on both the donor and the recipient and concern the definitions of donor death in relation to organ viability and the proper procedure for selecting recipients on the basis of age, health factors, and time on the waiting list.

Communications technology is also of critical importance to nurses. Cell phones, tablets, and other “smart” devices have made people and organizations more connected. They have also changed the nature of what people share with one another. The downside of this connectedness is that it can be difficult to separate what it is appropriate to share from what is inappropriate to share and when it is appropriate to do so. For example, an excited student nurse may snap a picture of herself and her preceptor on the first day of clinical education in the emergency department (ED). If she posts the photo to her social media page, the confidentiality of any patients in the background has been compromised. In addition, taking the photograph and posting it during the time designated for clinical education is ethically questionable, as it takes the student's attention away from learning and from providing high-quality patient care.

In this situation, the student nurse also opens herself up to questions that may present an ethical dilemma. Suppose a friend's father was admitted to the ED that day and the friend saw the picture. The friend may ask the student nurse whether she saw his father, what his father's condition is, and whether his father is still in the ED. The student nurse is faced with the ethical dilemma of answering her friend's questions or maintaining his father's privacy.

SAFETY ALERT Photos or comments posted to social media may be impossible to remove from the internet, even if you have deleted them from your social media accounts. Before posting anything that could negatively affect a patient or your career, consider the potential repercussions.

Patients now have unprecedented access to medical information through their smart devices. Patients can search for information about their symptoms or condition and find numerous sources within seconds. Unfortunately, not all health information available on the internet is up to date, accurate, or trustworthy. This can create ethical issues for nurses. For instance, during a patient interview, a nurse may learn that a patient is treating her condition using a remedy she found online. The remedy is unlikely to cause harm to the patient but is also unlikely to provide any benefit. The nurse feels uncomfortable addressing the issue for fear of upsetting the patient. The nurse must decide whether it is ethically responsible to allow the patient to continue with a remedy that he knows will not do her any good. Often, situations such as these can be avoided if nurses proactively direct patients to reliable online sources of health information.

Medical and communications technology converge in some areas of nursing. Electronic health records (EHRs) are one example of this convergence. EHRs offer patients ready access to their own medical records via their devices and allow providers to quickly get a comprehensive view of a

patient's history and care. In some organizations, care providers access EHRs on in-room computers or using tablet devices provided by the organization for that purpose. These records, although useful, present their own set of ethical dilemmas. For example, suppose a nurse knows that her brother is a patient at the clinic where she works. She suspects that he is ill, but when she asks him about it, he brushes her off. She can review his EHR via the clinic's system, but from a professional standpoint, she should not do so unless she is providing care to him at the clinic, a situation that in itself presents an ethical dilemma. Other issues may arise if a nurse fails to log out of an EHR access device before taking a break or notices that another nurse has failed to log out. In addition, it may be tempting for nurses to use devices designated for EHR access for unauthorized personal purposes.

Social Changes

Social beliefs and ideas are constantly changing, in part because of the advances brought about by new technology. The increasing interconnectedness of people around the globe contributes to the pace at which these ideas are spread. These changes bring with them a variety of ethical dilemmas for all members of society. They have a particularly big impact on healthcare providers because they often affect how people choose to live and maintain their health.

One particularly important change relates to the way in which people define life. Some believe that life should be allowed to end naturally; others believe that everything possible should be done to preserve life. Modern medical technology has made it possible to preserve or extend life for individuals who are terminally ill or in a vegetative state. These patients may survive for weeks or months with medical assistance. This assistance is expensive and draws on scarce clinical resources. Patients or their families may feel strongly about maintaining life via this technology even if healthcare providers do not consider it appropriate. Conversely, the patient or family may be strongly opposed to such treatments even if care providers think that they are necessary. The nurse must be prepared to provide care in either of these scenarios. In addition, the nurse may be called on to participate in difficult conversations about these topics with patients, their families, and other healthcare providers.

Closely related to this is the issue of quality of life. Although life can be prolonged or maintained, it may not include the freedoms and experiences that are considered important by many people. For example, suppose a 14-year-old cancer patient has been given 2 months to live. A new treatment may extend his life an additional 2 months but is likely to be very painful. The patient and his family must weigh whether length of life or quality of life is more important to them. Another potentially complicating issue here is the patient's age; his parents may be in favor of the treatment while the patient himself may be against it. Unless the care is being provided in a state that recognizes the decision-making capabilities of mature minors, the patient cannot make this decision for himself. (See the module on Legal Issues for more information about mature minors and minor consent.) This situation can be particularly challenging for the nurse who has strong personal opinions about the issues.

The way in which individuals define and pursue wellness is changing, too. One way this is evidenced is in the adoption of nontraditional diets. For instance, gluten-free

diets (in which only foods that do not contain gluten protein are consumed) have become much more popular. Some individuals adopt these diets because of celiac disease or gluten intolerance. For others, the diets are a conscious choice based on personal beliefs about health. Issues may arise, however, if patients' nutritional needs are not being met.

Complementary health approaches are also becoming increasingly popular. These include natural products—such as herbs and vitamins—and dietary supplements that contain these products. They also include mind and body practices such as yoga, meditation, and chiropractic manipulation. Some other complementary health approaches include traditional medicines, homeopathy, and naturopathy (National Center for Complementary and Integrative Health, n.d.). A number of complementary practices can be integrated into traditional healthcare in ways that benefit the patient. For example, incorporating massage therapy into treatment for a cancer patient may improve comfort and reduce stress. Ethical dilemmas arise, however, when a patient relies on a complementary treatment that either is ineffective or has potential to harm the patient.

Another social change is the increasing public support of the use of medical marijuana—either whole, unprocessed plants or their extracts—to treat diseases or symptoms (National Institutes of Health [NIH], 2017a). Research suggests that the chemicals in marijuana can be useful for treating a variety of illnesses. Legal use of medical marijuana is regulated on the state level; the federal government does not recognize or approve medical use of the drug. Medical marijuana has the potential to create ethical dilemmas for the nurse. For example, the nurse may believe that it is a useful and appropriate treatment for a patient's condition, but the patient may be adamantly opposed to consumption of the drug. The converse may also occur: The nurse is opposed, but the patient is in favor.

Conflicting Loyalties and Obligations

Because of their unique position in the healthcare system, nurses experience conflicts among their loyalties and obligations to patients, families, primary care providers, employing institutions, and licensing bodies. Patient needs may conflict with institutional policies, primary care provider preferences, needs of the patient's family, or even state or federal laws.

According to the ANA *Code of Ethics for Nurses* (ANA, 2015a), the nurse's primary commitment is to the patient. As part of that commitment, the nurse must engage the patient in care planning. In planning care with patients, it is not always easy to determine which actions best serve the patient's needs. For instance, the nurse may be aware that medical marijuana has been shown to be effective for a patient's condition. The patient has not responded to mainstream therapies, but medical marijuana is not legal in the state where the nurse and patient live. Although legal issues are involved, the nurse must determine whether, ethically, the patient should be made aware of this potentially effective alternative.

When planning and caring for a patient, the nurse must also consider the patient's family relationships. The nurse also has an obligation to the patient's family as well as the patient; however, it is important to remember that the nurse's first loyalty always lies with the patient. This is particularly important should conflicts arise between the patient and the family about care. Suppose a patient with necrotizing fasciitis

of the foot has been presented with several care options by her physician, including amputation. The patient wants to pursue amputation, but her spouse would prefer that she receive a different treatment. The nurse may help the patient and her spouse reach an understanding but is ultimately obligated to ensure that the patient's wishes are met.

The nurse may also have loyalties to colleagues and the healthcare organization. For example, suppose a hospital denies a \$2 per hour cost-of-living raise for the nursing staff. The staff as a whole chooses to strike, but each individual nurse must decide whether to honor the picket lines during the strike. The nurse may experience conflicting feelings about the need to support coworkers in their efforts to improve working conditions, the need to show loyalty to the organization, and the need to ensure that patients receive care and are not abandoned.

Ethical Dilemmas in Patient Care

Specific ethical issues related to human life or health often develop in the course of caring for patients. These issues are referred to as **bioethical dilemmas**. Bioethical dilemmas arise during the care of patients and families and often emerge from a combination of causative factors. HIV/AIDS, genetic testing, organ transplantation, and end-of-life decisions all present their own unique ethical dilemmas.

HIV and AIDS

HIV is a virus that attacks the immune system and eventually leads to AIDS. It is spread through contact with bodily fluids, including blood, breast milk, rectal fluids, semen, and vaginal fluids. Because contact with these fluids is often associated with sexual behavior and illicit drug use, HIV/AIDS bears a social stigma (De Bruyn, 2012). According to an ANA position statement on risk and responsibility in nursing, the nurse cannot set aside the moral obligation to care for the patient infected with HIV/AIDS unless the risk associated with providing that care exceeds the responsibility (ANA, 2015c). More information can be found in the exemplar on HIV/AIDS in the module on Immunity.

There is no safe or effective cure for HIV/AIDS, which means that an individual who contracts the virus will have it for life. However, antiretroviral therapy (ART) can effectively control HIV. Before the introduction of ART in the 1990s, HIV infection progressed to AIDS over the course of a few years; with ART, patients with HIV who receive early treatment can have close to a normal life expectancy (Centers for Disease Control and Prevention [CDC], 2016). Use of ART can also reduce the patient's risk of transmitting HIV.

Although ART is an important treatment that has changed the course of HIV infection for many patients, the combination of drugs involved is expensive. Private health insurance, Medicare, or Medicaid covers a portion of costs, but patients are responsible for deductibles and copayments, which may be costly. For patients without insurance, Medicare, or Medicaid coverage, the cost associated with ART may be prohibitive. This reality presents a number of ethical dilemmas, including whether it is ethical to allow a patient to endure a controllable condition because

of inability to pay. Programs such as the Ryan White HIV/AIDS Program and the Health Center Program attempt to address these issues by providing care and medication to individuals who could not otherwise afford it. The Health Center Program in particular serves individuals in minority and traditionally underserved communities, which tend to have higher HIV infection rates (AIDS.gov, 2014, 2015).

Patients have a duty to inform past and future sexual partners about their infection status. These conversations are difficult and have the potential to be confrontational; as a result, patients may avoid having them. The extended life expectancy and lowered risk of transmission associated with ART may help patients feel justified in this decision. Such a choice presents an ethical dilemma for the nurse. The nurse has an obligation to the patient to maintain his or her privacy, but the patient's partners also have a right to know they are at risk, to get testing, and to receive treatment if necessary (CDC, 2016).

Other ethical issues related to HIV/AIDS center on testing for HIV status and the presence of AIDS in healthcare professionals and patients. Questions arise about whether testing of all providers and patients should be mandatory or voluntary and whether test results should be released to insurance companies, sexual partners, and caregivers. As with all ethical dilemmas, each possibility has positive and negative implications for specific individuals.

Genetic Testing

Patients with genetic risk factors for chronic illness must make difficult decisions about genetic testing and test findings. For example, a patient with a family history of Huntington disease must decide whether to have predictive testing for the condition. If the test indicates that she will develop the condition, she must make decisions about the type of care she wants to receive in the future and whether to share information about her condition with others who may be affected by her diagnosis. Genetic testing can also present dilemmas for pregnant patients. If prenatal test results indicate a genetic condition, the patient must decide whether to undergo an elective abortion or deliver a child who may require medical and social support throughout his or her life.

Working with individuals who are seeking information about genetic testing for themselves or for their children is a new and interesting ethical challenge for nurses. The increasing prominence of genetics in the media has contributed to growing awareness among families and patients about inherited conditions (**Figure 44-2** »). As a result, patients are asking more questions of the nurses who care for them. The nursing code of ethics supports patients' rights to information and counseling in making genetic testing decisions. To provide the best information, nurses should know the legal requirements of their state related to genetic testing. For example, nurses should know whether their state requires parental consent for a minor to seek genetic testing and counseling.

It is important that nurses understand the limitations of genetic testing and explain them to patients in an unbiased manner. Genetic tests typically provide information about the nature of the condition a patient has or may be

Source: 400tmax/iStock/Getty Images.

Figure 44-2 » The “Have a Heart for Sickle Cell” campaign promotes the importance of genetic testing to help prospective parents determine their children’s risk for having the disease.

at risk for developing. They do not, however, provide information about the severity of the condition or about the age or timing of occurrence (Centre for Genetics Education, 2016). Understanding these limitations can complicate the ethical dilemmas genetic testing presents to patients, including the decision about whether or not to be tested. For this reason, organizations that provide genetic testing also offer genetic counseling.

Genetic counseling may not be available to patients who use direct-to-consumer genetic tests rather than physician-ordered genetic tests. Direct-to-consumer tests are purchased by individual patients, who collect a genetic sample at home and mail the sample to the laboratory that sells the test. Results are sent to the consumer by mail or email. Some companies that provide these tests connect patients to counselors or physicians who can explain the results; some do not (NIH, 2017b). This scenario may present nurses with a number of dilemmas. For example, patients may misinterpret their results and pursue treatment based on this misunderstanding. The nurse must decide whether to intervene and must be prepared to provide accurate information, support, and referrals as part of the intervention process.

Organ Transplantation

Organ transplantation is a sensitive issue in terms of both organ donation and organ allocation. In general, organs are

Source: Fstop123/iStock/Getty Images.

Figure 44-3 » Organ transplantation programs use formulas that balance utility, justice, and respect for persons to determine which patients receive organs.

procured from patients who are brain dead but whose hearts are still beating, though some organs may be recovered after circulatory death has occurred (McKeown, Bonser, & Kellum, 2012). Under the Uniform Anatomical Gift Act (UAGA), patients may elect to donate their organs after their death. Life support systems may be used around the time of death to maximize procurement of donor organs. According to provisions in the act, the need to use life support under UAGA overrides patient desires related to such measures in an advance directive. Although the intent of this provision is to prevent organ failure following brain death, it creates a clear ethical dilemma for healthcare providers, who may have to balance a patient’s wish to donate her organs and her wish not to be placed on life support. Educating patients and their families about these issues when discussing organ donation and advance directives may reduce the occurrence of these dilemmas.

Ethical issues also surround the allocation of donated organs, in part because there are many more patients in need of organs than there are organs available (**Figure 44-3** »). Typically, beyond the more clear-cut issues of tissue or blood type compatibility, geography, and organ size and the more ambiguous issue of medical urgency (United Network for Organ Sharing, 2015), organ transplantation programs use formulas that balance utility, justice, and respect for persons to determine which patients receive which organs and when they receive them. Utility weighs the good the transplant will do against the harm it may do. Justice explores whether distribution of the organ is fair. Respect for persons looks at the autonomy of the patients in decision making (Organ Procurement and Transplantation Network [OPTN], 2015). These concepts are abstract, often in conflict with one another, and difficult to apply to individual human lives. Suppose, for example, that two patients are in need of a liver but only one liver is available. One patient is a 60-year-old alcoholic with cirrhosis of the liver; the other is a 20-year-old with a hereditary condition who will die soon without a new liver. The 60-year-old is a brilliant scientist who conducts lifesaving research. The 20-year-old is young, with decades

Evidence-Based Practice

Individual Ethical Decision Making, Knowledge of Ethics, and Organizational Support

Problem

Nurses are faced with ethical dilemmas every day, and these dilemmas often must be resolved quickly. Research suggests that nurses may feel vulnerable both before and after dealing with ethically volatile situations. In some cases, nurses do not feel sufficiently competent in their knowledge of ethics to be comfortable with their role in the decision-making process; in other cases, nurses do not feel that they receive adequate organizational support.

Evidence

Numminen et al. (2015) explored newly graduated nurses' perception of ethics in the organizations in which they worked. In general, these nurses had a positive perception of the ethical climate; however, these positive perceptions were primarily reserved for patients, physicians, and fellow nurses. The organization itself and nurse managers were viewed less favorably. The nurses with the most positive perceptions of the ethical environment were those who self-identified as feeling very competent in their understanding of ethics.

Kim, Seo, and Kim (2016) assessed intensive care, medical-surgical, emergency, and oncology nurses on specific areas of difficulty in ethical decision making. Among the most significant difficulties, nurses identified a lack of education regarding ethics, a lack of organizational support for ethical decision making, and struggles to provide evidence-based care. However, the nurses' desire for organizational ethical support varied from department to department.

Jansen and Hanssen (2016) conducted a similar survey with psychiatric nurses. Their research suggested that nurses often felt squeezed between their own ethical values and the values of the organization as a whole. Nurses indicated that they often found themselves in the role of negotiator between the various stakeholder groups, which contributed to feelings of burnout and moral distress.

Implications

Nurses need organizational support in order to manage ethical dilemmas and cope with their role in the process. Kim et al. (2016)

identify ethical counseling as a means of preventing fatigue in nurses' personal and professional lives. They also suggest that unit-specific in-house training be provided to improve nurses' feelings of ethical competence and aid in the development of practical solutions to ethical problems.

Poikkeus et al. (2016) suggest that nurse leaders take a greater role in orienting nurses to the ethical procedures and practices on their units and facilitate multiprofessional discussions on ethics. They also support continuing ethics education for nurses.

Finally, Chooljian et al. (2016) encourage organizational ethics committees to serve in a supportive role for nurses. Typically, these committees are involved with nurses' ethical issues only when a dispute arises that requires committee attention. The researchers believe that organizations as a whole and nurses in particular could benefit from guidance and reassurance from the ethics committee throughout the decision-making process, even when the dilemmas involved do not require committee attention.

Critical Thinking Application

1. What conclusions can you draw about the way in which nurses build an ethical support network according to the research of Numminen et al.? In what ways do you think this type of support network is beneficial to nurses? In what way might it be detrimental to nurses?
2. In their research, Jansen and Hanssen describe that nurses feel squeezed between personal and organizational ethics. What does this suggest about the practicality of organizational ethics in clinical situations?
3. How would the increased involvement by organizational ethics committees suggested by Chooljian et al. improve the ethical climate of the organization? How would it help nurses avoid fatigue and burnout associated with ethical decision making?

full of potential ahead. Determining which patient receives the organ is an ethical dilemma that is only somewhat simplified by the use of an allocation formula based on the principles of utility, justice, and respect for persons.

» **Stay Current:** For more information on how donor kidneys from deceased individuals are allocated for transplant, visit the website of the United Network for Organ Sharing (UNOS) at <https://www.unos.org/transplantation/matching-organs/>

End-of-life Issues

Advances in medical technology and the increasing population of older adults have expanded the ethical dilemmas faced by older adults and the healthcare professionals who work with them. Some of the most frequent and disturbing ethical dilemmas for nurses involve death and dying. Euthanasia, assisted suicide, termination of life-sustaining treatment, and withdrawing or withholding of food and fluids are among these dilemmas.

In spite of increasing interest in and the urgent need for high-quality end-of-life care, there is no exact definition of the "end of life" interval or consensus about what constitutes end-of-life care (Izumi et al., 2012). Current definitions of

end-of-life care tend to be based on the time until death and the stage of illness. These definitions are problematic because the time frames involved are not always predictable, which puts patients at risk of being left without adequate end-of-life care (Izumi et al., 2012). Nurses who see a patient's life as a whole are better suited to understand the patient's condition and guide the patient and family through preparation for end of life (Watts, 2013).

Advance Directives

Many of the ethical dilemmas surrounding end-of-life care can be resolved if patients complete advance directives and ensure that they are available to healthcare providers. Advance directives are legal documents representing a patient's end-of-life decisions; they may include how patients want medical decisions to be made or whom they would like to make those decisions (Phillips, 2014). Advance directives instruct caregivers about patients' treatment preferences and provide an ongoing voice for patients when they no longer have the capacity to make or communicate decisions. An advance directive may provide instructions regarding do-not-resuscitate (DNR) orders, the withholding of emergency measures to sustain life, the termination of

life-sustaining measures, or any combination thereof. Nurses working with a patient who is experiencing a life-threatening event or who is approaching the end of life should make sure they understand the patient's advance directive as well as their employer's policies and procedures regarding advance directives. See the module on Legal Issues and the exemplar on End-of-Life Care in the module on Comfort for more information about advance directives.

Euthanasia and Assisted Suicide

Euthanasia, a Greek word meaning "good death," is sometimes referred to in the popular press as "mercy killing."

Active euthanasia involves taking direct action to bring about a patient's death, with or without patient consent (Johnstone, 2012b). An example of this is the administration of a lethal dose of medication to end the patient's suffering. Regardless of the caregiver's intent, active euthanasia is forbidden by law and can result in criminal charges against the individual who brings about the patient's death.

A variation of active euthanasia is **assisted suicide** (sometimes called "right to die"), in which patients are given the means to kill themselves if they request it. The ethics and morality of assisted suicide have been debated in the United States for a long time. For years, only Oregon, which passed the Death with Dignity Act in 1997, allowed physicians to provide lethal medications to qualifying patients who requested assistance (Drum, 2016). In January 2006, the U.S. Supreme Court upheld Oregon's assisted suicide regulations. After this decision, Washington (2008), Montana (2009), Vermont (2013), and California (2016) passed similar legislation. Several other countries also have assisted suicide laws in place.

Right-to-die legislation is still controversial in our society, and opposition to it by some cultural, religious, and other groups makes it an ethical issue that many nurses will be confronted with during their careers. The ANA's position statement on assisted suicide (ANA, 2013) states that performing active euthanasia and participating in assisted suicide violate the ANA *Code of Ethics for Nurses*. Nurses should understand the assisted suicide laws in their state so that they can adequately answer patients' questions; in doing so, they must be able to balance facts and patient concerns against their own personal biases and the ethics of their profession.

Withdrawing or Withholding Life-sustaining Therapy

Withdrawing or withholding life-sustaining therapy (WWLST) involves the withdrawal of extraordinary means of life support. It includes removing a ventilator, making no special attempts to revive a patient, and allowing the patient to die of the underlying medical condition (e.g., aspiration pneumonia). WWLST is a complex process that can take several days to complete. During that time, nurses must be prepared to manage the process, the complex emotions experienced by the patient's family, and their own feelings about the process (Stacy, 2012).

Antibiotics, organ transplants, and technologic advances such as ventilators can prolong life but do not necessarily restore health. Patients may specify that they wish to have

life-sustaining measures terminated; they may also include these wishes in advance directives or appoint a healthcare surrogate to make these decisions on their behalf. Even when WWLST is in accordance with the patient's wishes, it is often troubling for healthcare professionals to withdraw treatment. Nurses must understand that a decision to withdraw treatment is not a decision to withdraw care. As primary caregivers, nurses must ensure that sensitive care and comfort measures (palliative care) are given as the patient's illness progresses after withdrawal of treatment. When the patient is at home, nurses may provide this type of education and support through hospice services (see the module on Comfort for more information on hospice and end-of-life care).

Because withdrawal of treatment is difficult for families, it is very important that they fully understand the patient's treatment (Stacy, 2012). Families may misunderstand which treatments are life sustaining and which are palliative, and they may be confused when certain treatments are withdrawn while others are maintained. Keeping patients and families informed about the process is an ongoing concern, and it is important to keep in mind that family members need time to ask questions and discuss the situation. It is also essential for patients and families to understand that they can reevaluate and change their decision if they wish.

Withdrawing or Withholding Nutrition and Fluids

It is generally accepted that providing nutrition and fluids is part of ordinary nursing practice and, therefore, a moral duty. However, for patients who are dying or who are unconscious and not expected to improve, provision of nutrition and fluids is considered a medical intervention rather than a comfort measure (Danis, 2015).

During the dying process, patients exhibit decreased oral intake, progressive fluid deficits, and progressive accumulation of drugs. These changes can worsen existing symptoms or create new ones; these, in turn, lead to further declines in oral intake. Research consistently suggests that, when this occurs, it is more harmful to administer nutrition and fluids to the patient than it is to withhold them (Danis, 2015). As a result, nurses in this situation are morally obligated to withhold nutrition and fluids—or any treatment.

The nurse must also honor competent and informed patients' refusal of nutrition and fluids, referred to as voluntary cessation of intake. The ANA *Code of Ethics for Nurses* (2015a) supports this position through the nurse's role as a patient advocate and through the moral principle of autonomy. Some religions oppose voluntary cessation on the grounds that it involves a decision that will lead to patient death; however, some groups consider voluntary cessation preferable to euthanasia or assisted suicide (Danis, 2015).

Families may view provision of nutrition and hydration as important care and comfort measures and may strongly oppose withdrawal or withholding. This can create ethical dilemmas for the nurse. The nurse must be prepared to explain the withdrawal and withholding process to the family and why doing so is important. In addition, nurses should be familiar with the laws in their state pertaining to voluntary cessation.

Clinical Example A

Conner Wolfe is a 14-year-old patient with cancer who is refusing chemotherapy after becoming very ill and weak after his first round of chemo. His oncologist has made it very clear that Conner has a 90% chance of being cured if he undergoes chemotherapy followed by radiation and an equal chance that he will die without it. Although Conner and his family do not follow any specific spiritual or cultural traditions, they believe in using “natural medicine” for curing illness. Conner is adamant that he does not want any more chemotherapy. His parents state that he was in “better health” before the first chemo treatment and that is proof that the chemo is bad for him. When asked what the parents intend to do if Conner’s cancer metastasizes, the Wolfes say they will discuss that with Conner in the unlikely event that it occurs.

Critical Thinking Questions

1. What ethical dilemmas can you identify in this situation?
2. What is the nurse’s responsibility regarding addressing these dilemmas?
3. What, if any, action should the hospital take regarding Conner’s treatment? Why?

Ethical Issues in Nursing Practice

Ethics in nursing is not limited to bioethical dilemmas; it also includes nursing practice and the nurse’s identity as a moral agent. This identity is shaped by contextual and organizational forces that impact the role, obligations, and duties of the nurse. These forces include corporate healthcare values and hierarchies and the growing demand for healthcare (Edmonson, 2015).

Some everyday ethical challenges identified by nurses were categorized in a classic publication by Varcoe et al. (2004), who posited that nurses work as the “in-betweens.” Specifically, nurses are caught in between various other players involved in healthcare, including healthcare providers

and the patient, and the patient and the family. Nurses are also caught between family members, between staff members, between managers, and between other colleagues. Within these relationships, nurses must constantly balance their loyalties.

Conflicts also arise from traditional power structures in healthcare. For example, nurses have expressed concern about being intimidated or dismissed by physicians when the nurses report observations that are not congruent with the proposed medical treatment plan. They have also voiced anxiety about being ignored by senior medical staff when they report concerns related to physician behavior or by administrators when they express concern over corporate values. In some cases, nurses may be threatened with job and license loss over such reports and concerns.

Additional conflicts arise as a result of staffing shortages and other situations in which the organization functions inefficiently (Iglesias & De Bengoa Vallejo, 2012). When faced with inefficiencies, nurses must balance their limited time with the care that must be provided. In these situations, patient teaching, counseling, and support suffer as the nurse’s focus moves to performance of physical tasks and functions.

The behavior of nurses is shaped by their organizational and professional roles and the settings in which they work. Their responses to ethical dilemmas are inseparable from the scenarios in which those dilemmas arise (Johansen & O’Brien, 2015). Therefore, clinical experiences are important for helping nurses develop ethical behaviors. In addition, supportive colleagues, educators, and approachable and responsible managers are important resources for ethical practice. In fact, nurses have reported that having the opportunity to discuss ethical concerns is both personally and professionally sustaining (Johnstone, 2012a).

Focus on Diversity and Culture

Variations in Autonomy and Information Sharing

In providing ethical care to patients, it is important to understand the key role that culture plays in healthcare and the ways in which different cultures view autonomy and information sharing. For example, in the United States, autonomous individual decision making is highly valued; as a result, respect for patient autonomy is central to healthcare in this country. Autonomy is not a universal cultural value, however, and some patients from Chinese, Korean, and Hispanic backgrounds may prefer to involve family members or tribal or spiritual leaders in their decision-making process (Segal & Hodges, 2012). For example, in the Hmong culture, the clan leader may make the decision regarding whether or not an individual has surgery (Carteret, 2012).

It is also common for U.S. healthcare providers to disclose all information about a patient’s condition to the patient, including whether the condition is life threatening. In some other cultures, it is common to withhold information about terminal prognoses from patients. The rationale for this approach is that it enables the patient to maintain hope. Some patients from Central and South America, the Middle East, and Eastern Europe may prefer this approach. Chinese, Taiwanese, and Japanese patients may also subscribe to this ideology (Segal & Hodges, 2012).

In addition, cultural beliefs may require healthcare providers to carefully choose their language when disclosing information to patients and families. In some cultures, discussing the specifics of a patient’s condition is seen as impolite and disrespectful; some groups may even consider it dangerous. For example, the Navajo culture traditionally believes that speaking about something can result in that thing taking place. Thus, discussing death can make it occur. The underlying concern for this and other cultures with similar belief structures is that patients may become depressed, anxious, or hopeless as a result of a poor prognosis, and this can hasten their physical decline (Segal & Hodges, 2012). Nurses working with patients from cultures with these belief structures should seek guidance on strategies for imparting negative information. Elders, spiritual leaders, and colleagues from these cultures may be the most appropriate sources of reliable information.

Nurses may fear ethical or even legal repercussions related to information sharing or withholding from patients with diverse cultural backgrounds. It is important for the nurse to develop a relationship with the patient and family and work with them to determine the best means of sharing essential information based on their beliefs and values (Segal & Hodges, 2012).

Workplace Issues

A number of workplace issues outside of the bioethical realm affect nurses. Many of them are the result of financial constraints, personnel issues, and other organizational challenges. Two of the most common ethical dilemmas stemming from these factors involve limited resources and short staffing.

Allocation of Limited Health Resources

As healthcare costs continue to rise and more stringent cost containment strategies are implemented, allocation of limited supplies of healthcare goods and services has become an especially urgent issue. Examples of the goods and services affected include organs suitable for transplantation, artificial joints, and specialist services. The moral principle of autonomy cannot be applied if a patient cannot obtain the treatment he or she chooses. In these situations, healthcare providers may use the principle of justice by attempting to choose what is most fair to all. Nurses, other healthcare professionals, legislators, and patients must continue to look for ways to balance economics and care in the allocation of health resources. For more information on resource allocation in healthcare, see the modules on Managing Care and Healthcare Systems.

Short Staffing

Because of a nationwide shortage of nurses, nursing care is becoming a limited health resource. Short staffing is a critical concern because a number of studies link staffing levels to safe patient care (AACN, 2014). Unfortunately, some facilities continue to staff nursing units with fewer registered nurses and more unlicensed caregivers. When this occurs, staffing may not be adequate to ensure patient safety or allow nurses to provide an appropriate level of care. California is the only state that has enacted legislation mandating specific nurse-to-patient ratios in hospitals and other healthcare settings (Schultz, 2013). Unfortunately, this is not the simple solution that it might seem. The need to maintain adequate staffing levels could force changes elsewhere in the organization that are detrimental to patient care. For example, the need to maintain adequate staffing may force an ED to limit the number of patients it can accept at one time. As a result, patients in need of emergency care might be turned away when that limit is reached.

Clinical Example B

The director of nursing is having difficulty staffing all the units adequately. Two units have already been closed. The director can either spread the available staff around the facility and keep the remaining units open, but with fewer nurses than is really safe, or close more units. The director needs to consider the welfare of the institution, the nursing staff, and the patients.

Critical Thinking Questions

1. How would you assess the ethical aspects of this issue?
2. What actions would you take? Why?
3. How does the ANA *Code of Ethics* inform the possible actions?

Working with Patients and Families

Working with patients and families is both rewarding and challenging. Clear communication and good clinical decision-making skills help the nurse develop positive relationships with these individuals. Ethical challenges may still

arise, however; they include ensuring patient autonomy and maintaining patient privacy and confidentiality.

Patient Autonomy

Respect for patient autonomy is fundamental to nursing ethics, and nurses must recognize and defend the right of each patient to make his or her own decisions about healthcare. However, situations often arise in which patient autonomy is at risk. This risk may come in the form of a well-meaning family member who disagrees with the patient's decision or a physician or other healthcare provider who either fails to hear the patient's concerns or disagrees with the patient's request or decision (Rasmussen, 2012). In these situations, the nurse is ethically obligated to advocate for the patient's right to make his or her own decision.

Patient Privacy and Confidentiality

In keeping with the principle of autonomy, nurses are obligated to respect patients' privacy and confidentiality. Privacy is both a legal and an ethical mandate. The Health Insurance Portability and Accountability Act of 1996 (HIPAA) includes standards that protect the confidentiality, integrity, and availability of data and standards defining appropriate disclosures of identifiable health information and patient rights protection (see the module on Legal Issues).

Patients must be able to trust that nurses will reveal details about their history and care only when appropriate and will communicate only the information necessary to provide for their healthcare. Computerized patient records make sensitive data accessible to more people and make issues of confidentiality more complex and more important. Nurses should help develop and follow security measures and policies that ensure that patient data are used appropriately (see the modules on Informatics and Communication).

Academic Dishonesty

Ethical dilemmas are not just the concern of practicing nurses and are not limited to the workplace or to patient interactions; nursing students may find themselves facing ethical dilemmas in the classroom. Academic dishonesty is an important example of an ethical dilemma faced by nursing students. Examples of academic dishonesty include cheating, plagiarism, and failure to follow academic policies, such as the requirement to return examinations after test review sessions (Olafsen et al., 2013).

Academic dishonesty affects student nurses in two primary ways. First, there is the temptation for the student nurse to personally engage in academic dishonesty. Busy schedules and the need to maintain grades at a certain level can make dishonesty appealing; however, engaging in dishonesty negatively affects learning and personal growth and, in turn, the student's future nursing practice. Second, student nurses may witness or be aware of friends engaging in academic dishonesty. In these situations, balancing friendship and ethics can be difficult.

The way student nurses approach academic dishonesty is important to their development of personal ethics. In personal ethics, the individual makes decisions on the basis of his or her values and best interests (Lachman, 2012). The individual is accountable for the consequences of his or her actions. This is in contrast to a professional ethical dilemma,

in which the decision reflects the autonomy of the patient and the nurse is accountable to the patient's values and best interests. In spite of the differences between personal and professional ethics, personal ethics contribute to professional ethics. With increased experience and exposure on both personal and professional levels, students become better able to identify conflicting values and variables that affect the practicing nurse. See the clinical example that follows and **Box 44-5** ».

Clinical Example C

Elizabeth, a first-year nursing student, has obtained a copy of the first examination given last year in Nursing 110 from Jasmine, her assigned "Big Sister" from the second-year class. Jasmine emphasized that questions on nursing examinations are particularly hard to answer because they require application of information, not just recall. Elizabeth informs her selected study group that she has the exam and is willing to share it to help them focus their study time. You are a member of Elizabeth's study group.

Critical Thinking Questions

1. Will you participate? Why or why not?
2. Will you report Elizabeth to your instructor? Why or why not?
3. What ethical principle is involved in your decision process?
4. What conflicting values are involved in this scenario?
5. What additional information might help you make your decision? What difference does it make if you learn that Jasmine did not turn in the exam after a test review session?
6. What school policies are involved? What aspects of the ANA *Code of Ethics* apply?

Box 44-5

An Exercise in Ethical Decision Making

When ethical dilemmas arise, the individual often has the choice of multiple courses of action. To determine the best course of action, you must consider the pros and cons of each and the consequences that may result. This can be difficult to do, especially for individuals who are new to the concept of ethical decision making.

For this exercise, refer to the clinical example of Elizabeth and Jasmine. Then build your ethical decision-making skills by answering the following questions:

1. **Identify a range of actions with potential outcomes.**
What are the pros? What are the cons?
If you choose to participate in the study group and then inform the instructor?
If you choose to participate and not tell the instructor?
If you choose not to participate and not tell the instructor?
If you choose not to participate and to tell the instructor?
2. **Decide on a course of action and carry it out.**
What are you going to decide?
On what do you base your decision?
What does your decision tell others about you and your values?
Does your decision predict future decisions/actions?
3. **Evaluate/reevaluate the consequences of your decision/action.**
What tools would you use to evaluate your decision/action after the fact?
How would you determine what effect your decision/action had on others?

Coping with Ethical Dilemmas

Ethical dilemmas occur frequently in everyday clinical practice. They require decision and action on the part of the nurse, and they have important implications for compassionate, high-quality patient care (Epstein & Turner, 2015).

Nurses may be blindsided by ethical dilemmas and wonder why they did not recognize the potential for these dilemmas before they arose. Several ethical decision-making models have been proposed to assist nurses in these situations; however, these models may not always consider the underlying values of both the practitioner and the patient involved in the dilemma (Crowley & Gottlieb, 2012). The primary risk management model below is an example. It was designed to assist clinical staff in managing ethical decisions, and it includes the following:

- **Resource accumulation.** Acquisition of the requisite resources and skills before the occurrence of a stressor.
- **Time.** Engagement in "free time" activities to relieve pressure and anxiety in order to better perceive the subtle cues that alert the practitioner to potential ethical dilemmas.
- **Education.** Development of primary risk management skills through education and didactic training.
- **Organization and planning.** Enhancement of organization and planning through teaching and modeling.
- **Peer support and consultation.** Reliance on the practitioner's professional network, consisting of peers, supervisors, and colleagues, as a resource for primary prevention of ethical challenges (Crowley & Gottlieb, 2012, pp. 67–68).

Lifespan Considerations

When caring for patients at all stages of life, nurses may be faced with ethical dilemmas. Often, these dilemmas are specific to certain population groups; other times, they are related to bioethical issues common to patients of all ages. Regardless of the patient's age, the nurse must be prepared to handle these dilemmas in an ethically responsible manner.

Ethical Dilemmas Related to Infants and Children

Ethical dilemmas commonly arise in working with the pediatric population. This is in part because pediatric patients cannot make their own decisions. Parents or guardians have the authority to make healthcare decisions for their children. Dilemmas arise when parents and children do not agree on whether to go forward with a recommended treatment. In most cases, the nurse and other members of the healthcare team who have developed a therapeutic alliance with the child and family may be able to help the family reach a joint decision by providing additional information and opportunity to discuss their concerns calmly and openly.

In some cases, the healthcare team may need to seek guidance from the organization's ethics committee related to parental decision making for a minor child. For example, when there is a potential conflict of interest—such as

suspected child abuse and neglect—other measures may be necessary to provide appropriate care for the pediatric patient. In some cases, these measures may include obtaining a court order stating that the child is able to make his or her own decisions or assigning care decisions for the child to an individual or entity other than the parent, such as the Department of Child Services.

In addition to these concerns, the bioethical issues discussed previously in this exemplar can take on different aspects when applied to the pediatric population. WWLST decisions can be especially difficult when the patient is an infant, child, or adolescent. In discussing the withdrawal or withholding of medical treatment for pediatric patients with their parents, it is critical to provide complete, clear information about the child's condition, prognosis, degree of pain and suffering, and potential for good quality of life (Larcher et al., 2015).

When facing these situations, healthcare providers must follow the requirements of the Child Abuse and Treatment Act of 1984, which deemed withholding of medically indicated treatment as child abuse except in cases in which providing care is futile, that is, cases in which the treatments will not provide any clear clinical benefit (Ball, Bindler, & Cowen, 2017). Although it is rare for parents to refuse a medically indicated treatment that may benefit their child, the decision can be exceedingly difficult when the proposed treatment itself carries a high degree of risk, such as an organ transplantation or major surgery.

There are particular issues involving children as organ transplant recipients. For instance, the Organ Transplant and Procurement Network (OPTN) prefers to allocate organs from child donors—rather than adult donors—to child recipients. This is due to the difference in size between child and adult organs and the fact that children often respond better to organs from child donors (OPTN, n.d.). OPTN also encourages the use of special considerations in allocating organs that gives pediatric patients priority in some situations. These include the prudential lifespan account, in which the unique quality of life benefits enjoyed by child recipients is considered; the fair innings principle, in which the ability to maximize the recipient's lifespan is considered; and the maximin principle, in which giving priority to the most disadvantaged individual or group is considered (OPTN, 2014). Taken together, these concepts present ethical dilemmas that affect both child and adult patients in need of organ transplantation.

Ethical Dilemmas Related to Adolescents

Ethical dilemmas involving the adolescent population tend to focus on issues of consent and confidentiality. Parents or guardians must consent to medical treatment for adolescents under the age of 18 unless the adolescent has been emancipated, resides in a state that recognizes mature minors, or is seeking specific types of treatment recognized by state law, such as birth control, prenatal care, and diagnosis and treatment of sexually transmitted infections. Minors may also be able to give consent for mental health counseling and substance abuse treatment

(American Civil Liberties Union of Ohio, 2014; Goodwin et al., 2012).

Adolescent patients seeking care may wish to be examined without their parents being present; they may also prefer that their treatment remain confidential. Nurses should inform adolescent patients about mandatory reporting of imminent danger, evidence of abuse, and communicable diseases to the proper authorities (American Academy of Family Physicians [AAFP], 2016). Nurses should also notify adolescent patients that if the patient is covered under a parent's insurance, billing statements provided to that parent may include information about care. In addition, EHRs for minors are typically set up with parents as proxy. As a result, parents can read the information contained in the EHR unless the system is designed to restrict proxy access to confidential information (American College of Obstetricians and Gynecologists [ACOG], 2014).

Nurses must be aware of state statutes related to adolescent care and confidentiality as well as their ethical obligations to their adolescent patients. Nurses may encourage adolescent patients to involve their parents or guardians in care decisions related to sexual or mental health, but they must respect adolescent patients' right to autonomy in decision making. Failure to do so may give rise to patient concerns over confidentiality and result in patient refusal of treatment. For additional information, see the module on Legal Issues.

Ethical Dilemmas Related to Pregnant Women

Ethical issues related to pregnancy often focus on the delicate balance of maternal rights and fetal rights. For example, if a pregnant woman is in an accident that leaves her brain dead, it can be difficult to determine whether her life should be artificially sustained in order to deliver the child or whether life-sustaining technology should be discontinued. Two highly publicized cases occurred in 2014 and 2015. In one, the hospital attempted to keep the woman's body on life support against her wishes and those of her family (Goodwyn, 2014). In the other, the hospital and family collaborated to keep the woman's body alive for nearly 2 months, and her baby was born via cesarean section (Izadi, 2015). While the cases differed in many ways, they were similar in that the families and care providers faced a dilemma with no clear ethical or legal solution.

Ethical issues can also arise in situations in which the mother's life is in danger. This may occur as a result of complications of pregnancy that threaten the mother's life or as a result of medical conditions unrelated to pregnancy, such as cancer. In these situations, the woman, family, and healthcare providers are faced with the difficult question of whether the mother's life or the child's life takes priority. In these situations, personal opinions about abortion and the medical necessity of treatments that could harm the fetus complicate the decision-making process.

Fetal protection laws enacted by some states have complicated the ethics of healthcare during pregnancy. The intent of these laws is to protect mothers and fetuses from individuals who abuse them; however, broad interpretation of these laws has led to questions about the mother's right to

accept or decline certain tests and treatments during pregnancy (Graham, 2014). Fetal protection laws are discussed further in the module on Legal Issues.

The discussion of maternal and fetal rights often stirs up complex emotions and strong opinions about the ethics and morality of pregnant patient care. Nurses should understand their state laws and organizational policies on these topics. They should also understand their rights and responsibilities related to conscientious objection (Lachman, 2014). For more information on this topic, see the module on Legal Issues.

Ethical Dilemmas Related to Older Adults

End-of-life issues are common sources of ethical dilemmas for nurses working with the older adult population. These may include issues associated with advance directives, assisted suicide, withdrawal or withholding of life sustaining treatment, and withdrawal or withholding of nutrition and fluids.

Issues related to autonomy, competency, and decision making also commonly arise in the older adult population. Some older adults experience age-related cognitive impairments or untreated depression that may affect the decisions they make related to healthcare. In addition, family members or caregivers may have strong opinions about what the patient should or should not do and may question the patient's ability to make healthcare decisions (Seamen & Erlen, 2013). The combination of these factors can place the nurse in a difficult position. If the patient is competent to make her own medical decisions, the nurse must respect her

autonomy in decision making. However, the nurse must consider the factors that may be at work and the risks and benefits associated with a treatment. In addition, the nurse must be prepared to face anger, disappointment, and questions from the patient's family. When these situations arise, it may be useful for the nurse to facilitate a discussion between the major stakeholders—including the physician, patient, and family—to ensure that everyone understands what the treatment entails and what its risks and benefits are and to help the patient reach a decision that affirms her autonomy while being acceptable to the other parties involved (Seamen & Erlen, 2013).

Consent can also present issues with older adult patients who have been hospitalized. Typically, when patients are admitted to the hospital, they sign a blanket consent for treatment. By signing this form, the patient gives implicit consent for routine care. However, the patient can refuse or question any individual treatment. For example, the patient may refuse to allow the nurse to draw blood or administer a medication. When these situations arise, the nurse must respect the patient's autonomy, even if the nurse disagrees with the patient's decision. In many cases, these dilemmas can be worked through if the nurse explains the procedure and its purpose to the patient and asks about his or her reasons for refusing it (Seamen & Erlen, 2013).

SAFETY ALERT Forcing or coercing a patient to have a procedure that the patient has refused is unlawful and can result in legal consequences for the nurse.

REVIEW Ethical Dilemmas

RELATE Link the Concepts and Exemplars

Linking the exemplar of ethical dilemmas with the concept of legal issues:

1. What are your beliefs about advance directive planning for any patient who has a chronic illness, such as a cardiac illness, diabetes, or renal failure, regardless of the patient's age?
2. What is the nurse's role in discussing future care plans, such as end-of-life care, with chronically ill patients?

Linking the exemplar of ethical dilemmas with the concept of comfort:

3. What are your beliefs about ensuring comfort for patients with chronic pain?
4. Assess your understanding of pain management options to ensure comfort. What are your beliefs about the use of high-level narcotics for patients?

REFLECT Apply Your Knowledge

David Lewis is a 50-year-old man who is recovering from a stroke at a rehabilitation facility. He is medically stable and able to participate fully in his therapies. However, he has requested DNR (do-not-resuscitate) status. He reasons that if he has another stroke or cardiac arrest, he could lose much more cognitive and motor function, and if he were resuscitated after such an event, it would place too heavy a burden of care on his family. Day after day, he and his family ask about the DNR order. The nurses working with Mr. Lewis repeatedly ask the attending physician for an order, and the physician continues to respond that Mr. Lewis does not need a DNR order—he is stable. Finally, the primary nurse goes to the facility's ethics committee to discuss the problem. This results in another physician reviewing the chart, speaking with the patient and family, and entering the DNR order.

1. What ethical dilemma did the primary nurse working with Mr. Lewis face?
2. What principles did the primary nurse follow in going to the ethics council?
3. How do you feel about DNR orders? Why?
4. In what ways did the nurses working with Mr. Lewis advocate on his behalf? How is the nurse's role as an advocate related to nursing ethics?

Exemplar 44.C Patient Rights

Exemplar Learning Outcomes

44.C Analyze patient rights as they relate to ethics.

- Examine the rights of patients in the healthcare system.
- Analyze support systems that exist for patients who feel that their rights have been violated by a healthcare agency or provider.
- Compare the contents of different documents or laws that address patient rights.
- Differentiate considerations related to patient rights across the lifespan.

Overview

All patients have rights when it comes to the healthcare they receive. Popularly called **patient rights**, these represent the fundamental care owed to patients by healthcare providers and the government (WHO, 2016). Some of these rights are guaranteed by federal law, such as the right to informed consent mandated in the Patient Self-Determination Act (see the module on Legal Issues). Other rights are governed by state laws. In addition, healthcare organizations often have a patient bill of rights, which details the rights the organization promises to uphold for its patients.

The importance of patient rights is evident in the American Nurses Association's Standards of Practice and Code of Ethics and the accreditation standards for various types of healthcare agencies set by The Joint Commission. The Joint Commission also encourages patients to become more informed about their rights and more involved in their care through the Speak Up program (The Joint Commission, 2013b). The essential points of this program are outlined in **Box 44-6** ».

Nurses should be aware of national and state laws pertaining to patient rights, as well as their employer's policies and procedures. Nurses should also be knowledgeable about the standards enacted by professional nursing bodies in an effort to protect patient rights and ensure nurse compliance with applicable laws.

Beyond laws, policies, and standards, nurses should understand their role in protecting patient rights. In addition, nurses should introduce patients to their patient rights and responsibilities and encourage patients to engage as partners with their healthcare providers. Methods of doing so will vary depending on the patient's age and condition, but it is an important component of the nurse's role as a patient advocate.

Protecting Patients' Rights

In spite of the legal requirement and ethical duty to protect patient rights, many patients still experience violations of these rights as they navigate the healthcare system. Some of the most common violations involve confidentiality, privacy, informed consent, and nondiscrimination. Less commonly, violations may involve treatment that does not respect the

Patient Rights from The Joint Commission's Speak Up Campaign

Know Your Rights

- You have the right to be informed about the care you will receive.
- You have the right to get important information about your care in your preferred language.
- You have the right to get information in a manner that meets your needs, if you have vision, speech, hearing or mental impairments.
- You have the right to make decisions about your care.
- You have the right to refuse care.
- You have the right to know the names of the caregivers who treat you.
- You have the right to safe care.
- You have the right to have your pain addressed.
- You have the right to care that is free from discrimination. This means you should not be treated differently because of age, race, ethnicity, religion, culture, language, physical or mental disability, socioeconomic status, sex, sexual orientation, or gender identity or expression.
- You have the right to know when something goes wrong with your care.
- You have the right to get a list of all your current medications.
- You have the right to be listened to.
- You have the right to be treated with courtesy and respect.
- You have the right to have a personal representative, also called an advocate, with you during your care. Your advocate is a family member or friend of your choice.

dignity of the patient or that jeopardizes the patient's healthcare outcomes (Cohen & Ezer, 2013).

To protect patient rights, nurses must follow requirements related to informed consent. They must also be aware of the patient protection systems in place within their organizations and their state. In addition, they must recognize the importance of patient bills of rights and patient responsibilities in patient care.

Informed Consent

To ensure patient rights, the nurse must first identify the appropriate individual to provide informed consent for the patient (e.g., patient, parent, legal guardian). Also, it is vital to provide written materials in the patient's spoken language. The nurse needs to understand and describe components of informed consent and how to participate in obtaining informed consent.

When obtaining informed consent, the nurse must understand how to verify that the patient comprehends and consents to care and procedures. In addition, the nurse must discuss various treatment options and decisions with the patient. Similarly, the nurse must educate patients and staff about patients' rights and responsibilities (e.g., ethical/legal issues) and know how to evaluate patient and staff understanding of patients' rights.

SAFETY ALERT When discussing informed consent with patients, the nurse should explain to the patient his or her right to refuse a treatment or procedure.

Organizational and State Protections

Individual patients who feel that their rights are in danger or have been violated have a number of options. Many health-care organizations have patient advocates who help patients navigate the organizational system and intervene when necessary to ensure that the patient's rights are respected. This type of advocacy is particularly important for patients who require long-term care. In addition, many states have offices designated by the governor or secretary of health to assist patients with issues related to patient rights in long-term care.

The state department of health may also be able to help with patient rights issues. Nursing homes, homes for frail

older adults, and licensed facilities for people with disabilities are regulated at the state level, and violations committed by these agencies may be reported for investigation (Hicks et al., 2012). Legislatures in many states have also passed declarations of patients' rights that must be followed by nursing homes and other agencies that provide medical care and housing for patients.

Patient Bills of Rights

The first patient bill of rights was drafted by the American Hospital Association during the 1970s; since then, a number of different groups have created their own patient bills of rights (American Cancer Society, 2016). For example, in 1998, the U.S. Advisory Commission on Consumer Protection and Quality in the Health Care Industry adopted a bill of rights. This bill included, among other things, provisions about information disclosure, provider and plan choice, access to emergency services, participation in treatment decisions, nondiscrimination, and confidentiality. It also included information about filing complaints and appeals (President's Advisory Commission on Consumer Protection and Quality in Healthcare, 1998). The bill was intended to protect all consumers and was adopted by the federal government for employees covered under their insurance plans. A summary of this bill of rights is provided in **Box 44-7** >>.

The 1998 bill of rights served as the inspiration for a number of other patient bills of rights. Hospitals, patient organizations, government agencies, and insurance plans are among the different groups that have created patient bills of rights. Patient bills of rights have also been developed for hospice patients and patients with mental illness. Although these bills of rights differ from one another to some degree, most discuss privacy and confidentiality, nondiscrimination, language preferences, and patient involvement in treatment decisions.

Box 44-7

A Summary of the Bill of Rights of the U.S. Advisory Commission on Consumer Protection and Quality in the Health Care Industry

- **Information disclosure.** You have the right to accurate and easily understood information about your health plan, healthcare professionals, and healthcare facilities. If you speak another language, have a physical or mental disability, or just don't understand something, help should be provided so you can make informed healthcare decisions.
- **Choice of providers and plans.** You have the right to a choice of healthcare providers who can give you high-quality healthcare when you need it.
- **Access to emergency services.** If you have severe pain, an injury, or sudden illness that makes you believe that your health is in serious danger, you have the right to be screened and stabilized using emergency services. These services should be provided whenever and wherever you need them, without the need to wait for authorization and without any financial penalty.
- **Participation in treatment decisions.** You have the right to know your treatment options and to take part in decisions about your care. Parents, guardians, family members, or others who you select can represent you if you cannot make your own decisions.
- **Respect and nondiscrimination.** You have a right to considerate, respectful care from your physicians, health plan representatives, and other healthcare providers that does not discriminate against you.
- **Confidentiality of health information.** You have the right to talk privately with healthcare providers and to have your healthcare information protected. You also have the right to read and copy your own medical records. You have the right to ask that your physician change your record if it is not accurate, relevant, or complete.
- **Complaints and appeals.** You have the right to a fair, fast, and objective review of any complaint you have against your health plan, physicians, hospitals, or other healthcare personnel. This includes complaints about waiting times, operating hours, the actions of healthcare personnel, and the adequacy of healthcare facilities.

Source: Based on President's Advisory Commission on Consumer Protection and Quality in the Health Care Industry. (1998). Consumer bill of rights and responsibilities: Executive summary. *Agency for Healthcare Research and Quality*. Retrieved from <http://archive.ahrq.gov/hcqual/cborr/exsumm.html>.

Passage of the Affordable Care Act in 2010 was accompanied by a new patient bill of rights. This bill differs in content from other bills of rights in that it specifically addresses patient protections related to health insurance coverage. Areas discussed in this patient bill of rights include coverage for individuals with preexisting conditions, free preventive care, elimination of dollar limits, accountability for rate increases, and provider choice (HealthCare.gov, n.d.). The Affordable Care Act may be replaced in the coming years. Nurses should stay abreast of changes in healthcare laws and the way in which they affect patients.

Patient Responsibilities

In addition to patient bills of rights, some organizations now publish lists of **patient responsibilities**. These lists emphasize that healthcare is a partnership between the patient and caregivers, that other patients have the right to be comfortable, and that there are consequences when patients do not comply with treatment plans. Common patient responsibilities include the following:

- Tell your healthcare team how you feel.
- Provide information about your health, past illnesses, and use of medications.
- Report accurate and complete information about your health to your healthcare team.
- Ask your healthcare team whether you need to change your medications before a procedure or test.
- Answer questions asked by your healthcare team.
- Cooperate with your healthcare team.
- Listen to instructions, read written material given to you, and ask questions if you do not understand something.
- Be considerate of the staff and other patients by limiting visitors, following smoking regulations, and using the telephone and television so as not to disturb others.
- Provide information about your health insurance, and work with the hospital to arrange for payment if needed.
- Recognize the effects of your lifestyle on your health, and work with your hospital team to change your lifestyle as necessary.
- Follow the treatment plan recommended by your healthcare team.
- Accept the consequences if you fail to comply with instructions given to you.

Patient responsibilities lists are intended to encourage patients to take a more active role in their care and promote consideration of others within the healthcare environment. They are not intended to be a list of rules that patients must follow. In introducing patients to these responsibilities, it is important for nurses to make sure patients understand this difference.

Lifespan Considerations

At different points in the lifespan, patients experience different needs and concerns related to patient rights. In addition, some organizations have patient bills of rights that are specific to patients at different points in the lifespan. The nurse must ensure that the specific rights of these patients are respected.

Patient Rights Pertaining to Infants and Children

When working with pediatric patients, nurses are responsible for protecting the rights of both patients and their families. To support nurses in these efforts, the Association for the Care of Children's Health (ACCH) has developed the pediatric bill of rights, which outlines the need for family-centered care that provides developmentally appropriate psychosocial support. The Society of Pediatric Nurses (SPN) encourages hospitals and children's units across the country to adopt some version of this bill of rights (Mott, 2014). In doing so, the SPN hopes to better prepare families to understand the care that is being provided to their child and to create more positive healthcare experiences for pediatric patients and their loved ones.

A central theme in the pediatric bill of rights is allowing patients and families to remain together whenever possible during treatments and hospital stays. In some cases, this includes making arrangements for a family member to remain with the child overnight. Other supportive measures include allowing the child to have toys or clothes from home when possible and providing children with opportunities to play and engage in activities related to their personal interests. The goal of all these measures is to make patients and families comfortable and to maintain a sense of normalcy rather than emphasizing the child's illness (Mott, 2014).

The pediatric bill of rights includes many of the same provisions as other patient bills of rights with relation to privacy, information sharing, and respect for the individual. The primary difference is the focus on age-appropriate and developmentally appropriate applications of these concepts. Another difference is the application of these concepts to the family as a whole rather than to the patient as an individual.

Patient Rights Pertaining to Adolescents

Adolescent patients are also covered under the pediatric bill of rights. An important difference in caring for adolescents rather than young children is the role of family. As children reach adolescence, they may engage in behaviors or have care needs that they are embarrassed or worried about sharing with their families. In these situations, it is essential that nurses understand the state laws related to confidential care for adolescents and are prepared for the ethical dilemmas involved in providing this kind of care. (See the module on Legal Issues and the exemplar on Ethical Dilemmas in this module for more information.)

The pediatric bill of rights includes a privacy provision that is useful for working with adolescent patients. It states that patients have the right for their privacy to be honored as long as it is safe for the patient (Mott, 2014). Though the right of privacy must be honored, the American Academy of Family Physicians encourages healthcare providers to make a reasonable effort to encourage adolescents to involve their family in their healthcare (AAFP, 2016). This encouragement should be provided in a supportive manner with the clear understanding that involving parents or guardians in the decision-making process is not essential for the patient to receive care.

Another important consideration in caring for adolescent patients is their inclusion in nonconfidential healthcare decisions. For example, a teenage patient being treated for leukemia

may have strong opinions about the types of treatment he would like to receive, even though his parents serve as his decision-making proxy. Adolescent patients have a right to have their opinion heard and considered by healthcare providers and family members (Dikema, 2014). The nurse must facilitate conversations with family and other healthcare providers in these situations. See the Ethical Dilemmas exemplar in this module for more information on this topic.

Patient Rights Pertaining to Pregnant Women

Many pregnant patients may not be fully aware of their rights in regard to making healthcare decisions on behalf of themselves and their children and so may not exercise their rights. As a result, a major rights-related issue that nurses face with this population involves informing patients of their rights. Rights specific to the pregnant patient include the right to prenatal care, the right to choose a physician or midwife, and the right to give birth in the setting of her choice (see Focus on Diversity and Culture feature). In addition, the pregnant patient has the right to move freely during labor, to deliver in the position of her choice, and to have uninterrupted contact with her newborn provided that neither mother nor child experience a medical condition that prevents this (Childbirth Connection, 2006).

Focus on Diversity and Culture Diversity in Labor and Delivery

A pregnant patient has the right to receive labor and delivery care in accordance with her cultural background (Childbirth Connection, 2006). For example, patients from African cultures may choose to have their mothers or respected female elders in the delivery room rather than the child's father. Middle Eastern patients may prefer to walk or remain otherwise mobile during the labor process and to squat during delivery. Chinese, Japanese, Vietnamese, and Korean patients may remain silent during the birthing process because of the traditional belief that crying out takes energy away from laboring. Patients from East Indian cultures may have the child's father or grandfather whisper traditional prayers to the infant immediately following birth (HealthCare Chaplaincy, 2013).

If these actions do not jeopardize the mother or the child, the nurse must respect the mother's wishes for culturally based practices. The nurse should also advocate with other healthcare providers for the patient's right to engage in these practices (Kang, 2014).

A number of issues can develop that endanger a pregnant patient's rights. For example, the patient's right to prenatal care depends on the patient's access to care. As a result, patients without health insurance or in underserved communities may not be able to exercise this right. In addition, labor and delivery rights may be affected by organizational or unit regulations that limit patient movement, by healthcare providers who are unaware of the various rights of the pregnant patient, or by medical emergencies that necessitate that certain protocols be followed. The nurse should work with the patient and other providers to protect the patient's rights to the extent possible in a given situation.

Patient Rights Pertaining to Older Adults

One of the biggest patient rights issues for older patients involves long-term care provided in nursing homes and in skilled nursing facilities. Federal law requires that nursing homes protect and promote the rights of each resident. These include the rights of nondiscrimination, respect, freedom from abuse and neglect, and freedom from physical restraints. In addition, residents must be informed about fees and services in writing before admission, be allowed to manage their money as they see fit, be allowed to keep personal property in their rooms, and be able to see the healthcare provider of their choice. Visitors must be allowed during reasonable hours, and necessary social services must be provided to residents. Residents must be able to file complaints without fear of reprisals and cannot be transferred or discharged unfairly (Medicare.gov, n.d.). Recently the Centers for Medicare and Medicaid Services (CMS) issued a rule that bars nursing homes that receive federal funding from requiring that residents resolve disputes in arbitration instead of in court, making it easier for residents of nursing homes and their families to sue if necessary for claims such as elder abuse, sexual harassment, and wrongful death (CMS, 2016).

The rights of older patients may also be endangered in hospital settings, particularly if friends or family members are concerned about the patients' capacity for making their own medical decisions. In addition, the rights of patients who are no longer able to speak or make decisions for themselves may be at risk if the patients do not have advance directives in place. These issues are discussed in greater detail in the module on Legal Issues and in the exemplar on Ethical Dilemmas in this module.

REVIEW Patient Rights

RELATE Link the Concepts and Exemplars

Linking the exemplar of patient rights with the concept of healthcare systems:

1. Patients have the right to emergency care without bias. What are your beliefs about patients who use emergency care in place of primary care?
2. What are your beliefs about patient privacy when emergent or critical care is needed and the patient cannot provide approval for his or her own care?

Linking the exemplar of patient rights with the concept of addiction:

3. Patients with persistent admissions for alcohol withdrawal therapy due to alcohol addiction need support to make the decision to get over this addiction. What are your beliefs about alcohol addiction and the nursing role in assisting a patient with these issues?
4. When adults who have had an extensive history of back pain with several narcotics taken each day need surgery, they often require a higher level of narcotics postoperatively. What is the nurse's role in supporting this type of patient in appropriate pain management?

REFLECT Apply Your Knowledge

James Casper is a 75-year-old widower who was admitted to the ED after a hit-and-run accident. Upon arrival, he was intubated, a chest tube was inserted, and he was rushed into surgery to repair damage to his spleen. After surgery, he was taken to the trauma unit to recover.

Mr. Casper has been on the trauma unit for 3 days now. He is awake and alert but still reports that he is experiencing pain. He has become increasingly agitated during his time on the unit. He has also complained repeatedly about nurses' "constant poking and prodding" of him. He has refused to see his daughter on several occasions when she has come to visit him.

Today, Candace Jones, the nurse assigned to Mr. Casper, has come to perform a venipuncture to get a blood sample for lab testing. Mr. Casper refuses to allow her to draw the blood. At first, he simply refuses to give her his arm; then, he began to yell at Ms. Jones and verbally berate her.

1. Upon admission into the ED, Mr. Casper signed a general consent for care form. Does this form supersede his right to refuse the venipuncture? Why or why not?
2. What is Ms. Jones' best means of proceeding in this situation without violating Mr. Casper's rights?
3. In what way has Mr. Casper violated his patient responsibilities in this scenario?

Module 45

Evidence-Based Practice

Module Outline and Learning Outcomes

The Concept of Evidence-Based Practice

Overview of Evidence-Based Practice

45.1 Summarize the evolution of evidence-based practice.

Concepts Related to Evidence-Based Practice

45.2 Outline the relationship between evidence-based practice and other concepts.

Nursing Clinical Research

45.3 Summarize the fundamentals of research methodology.

Developing Evidence-Based Practice

45.4 Analyze the four steps of developing evidence-based practice.

Lifespan Considerations

45.5 Differentiate considerations related to evidence-based practice throughout the lifespan.

Strategies to Implement Evidence-Based Practice

45.6 Outline activities used to implement evidence-based practice.

>> The Concept of Evidence-Based Practice

Concept Key Terms

Background questions, 2766	Evidence-based practice (EBP), 2761	Institutional review boards (IRBs), 2765	PICOT, 2767	Research, 2761
Evidence, 2761	Foreground questions, 2766	Nursing clinical research, 2764	Qualitative research, 2764	Research participants, 2765
Evidence-based nursing, 2761	Informed consent, 2765	Nursing research, 2764	Quantitative research, 2764	Translational research, 2762

The Institute of Medicine's (IOM) 2000 publication *To Err Is Human* established the high cost of medical errors, including the cost in terms of human life. The IOM's 2001 publication *Crossing the Quality Chasm: A New Health System for the 21st Century* addressed the failure of the healthcare delivery system to consistently provide high-quality healthcare to all people. Evidence-based practice is one response to intensifying public and professional demands for safety and high quality improvement in health care. Goals of evidence-based practice include using the best evidence to reduce inappropriate variations in healthcare and to facilitate the standardization of safe, effective healthcare practices (Stevens, 2013).

Overview of Evidence-Based Practice

Evidence-based practice (EBP) is used to form a bridge between **research** (a formal, systematic way of answering a question or approaching a problem) and nursing

practice. **Evidence** can be defined as clinical knowledge, expert opinion, or information resulting from research. Although there are many definitions of EBP, they generally include three components: (a) the best evidence from the most current research available, (b) the nurse's clinical expertise, and (c) the patient's preferences, which reflect values, needs, interests, and choices (see a **Figure 45-1 >>**). By integrating the three components of EBP into the clinical decision-making process, nurses can individualize patient care and provide best practice for patient-centered care.

Although different professional organizations and healthcare agencies vary slightly in their definitions, most agree that **evidence-based nursing** seeks, considers, and synthesizes the combination of the best available research evidence, the nurse's own clinical experience, and each patient's cultural values and personal preferences to provide individualized, optimal nursing care appropriate for the patient at the point of care (Sigma Theta Tau International, 2002; American Association of Nurse Anesthetists, n.d.; UNC Health Sciences Library, 2016).

Figure 45-1 » These three components provide the framework for evidence-based practice that nurses use to provide optimized individual clinical care to patients.

Implementing research evidence is not a new concept (**Box 45-1** »). However, a reordering of priorities in the medical field led to an emphasis on practice-oriented research. In the early 1970s, Dr. Archie Cochrane, a British epidemiologist who is generally credited with developing EBP, campaigned among healthcare providers to use evidence when making healthcare decisions. Professional nursing organizations saw the wisdom in this idea and encouraged nursing research in the development of best nursing practice based on current best knowledge. In 1996, Dr. David Sackett and colleagues provided the following commonly accepted definition of EBP: “The conscientious, explicit and judicious use of current best evidence in making decisions about the care of the individual patient. It means integrating individual clinical expertise with the best available external clinical evidence from systematic research” (Sackett et al., 1996, p. 71).

Translational research is a systematic approach of converting research knowledge into applications of healthcare for improved patient outcomes. The translation of scientific evidence into practical applications allows for enhanced human health, particularly when information flows back and forth between researchers and clinicians, allowing for further investigation of diseases and their effects on humans. The National Institutes of Health supports translational research through the Clinical and Translational Science Awards Consortium. The Centers for Disease Control and Prevention has translational centers around the country. Educational institutions are partnering with communities to do translational projects.

Translational research has clear benefits for the development of EBP across nursing and the various disciplines involved in healthcare systems. In particular, translational research may speed the process from discovery to application. However, this potential benefit also carries risks. Researchers have expressed concerns that rapid translation may lead to the introduction of applications and technologies that have not been sufficiently evaluated from ethical and social perspectives (Ostergren et al., 2014).

Box 45-1 Florence Nightingale

Florence Nightingale introduced to nursing the importance of collecting data through the process of observation to help make decisions about the health status of an individual (see **Figure 45-2** »). As Nightingale (1859/1946) explained:

The most important practical lesson that can be given to nurses is to teach them what to observe—how to observe—what symptoms indicate improvement—what the reverse—which are of importance—which are of none—which are the evidence of neglect—and of what kind of neglect. All of this ought to make part, and an essential part, of the training of every nurse. (p. 59)

Observation continues to be one of the most powerful tools in nursing practice. Nurses employ physical assessment, including observation, as a way to gain immediate information about a patient’s health status. EBP extends the nurse’s realm of information to incorporate research—the data observed and recorded by others—to improve patient outcomes.

Figure 45-2 » A ward of the hospital at Scutari where Florence Nightingale worked, from an 1856 lithograph by William Simpson. In the 1800s, Nightingale changed her concepts of disease prevention and promotion of health when she observed patients with and without the advantage of sanitation measures during their care. She concluded that patients situated in well-ventilated rooms and treated with clean equipment and supplies, such as fresh linens and dressings, healed faster and had fewer complications. Washing hands resulted in a decrease in patient deaths. This is an example of an early informal randomized controlled trial that provided objective evidence to support a change in best practice for nurses to improve patient outcomes.

Concepts Related to Evidence-Based Practice

EBP has widespread implications for all areas of nursing, because it informs nursing procedures during the day-to-day care of patients. From simple tasks, such as the use of standard hand hygiene procedures to prevent infection and turning patients every 2 hours to prevent pressure injuries,

Concepts Related to Evidence-Based Practice

CONCEPT	RELATIONSHIP TO EVIDENCE-BASED PRACTICE	NURSING IMPLICATIONS
Accountability	Best practice standards of care, responsibility, and scope of nursing practice reflect EBP.	<ul style="list-style-type: none"> Nurses are responsible for providing best current nursing care to their patients.
Clinical Decision Making	EBP provides scientific support for nurses in clinical thinking processes, making decisions, and using clinical judgment.	<ul style="list-style-type: none"> As problem solvers, nurses depend on current best practice to deliver high-quality care throughout the individual patient's nursing plan of care.
Health, Wellness, and Illness	Routine habits, including sleep patterns, hygiene practices, and exercise, impact an individual's current and future state of health and wellness.	<ul style="list-style-type: none"> Nurses are responsible for educating patients about evidence-based self-care practices that promote health and wellness and that reduce the risk for illness.
Legal Issues	The evidence that supports EBP includes clinical knowledge, expert opinion, and information resulting from research. Evidence serves as an essential component of the foundation for professional nursing's scope and standards of practice.	<ul style="list-style-type: none"> Conduct that deviates from professional standards of practice constitutes malpractice.
Professional Behaviors	As a credible professional discipline, nursing has a responsibility to use EBP.	<ul style="list-style-type: none"> Best evidence needs to be integrated with the nurse's clinical experience and patient preferences.
Quality Improvement	Improving nursing care is a continuous process using current evidence to deliver safe and effective interventions resulting in best patient outcomes.	<ul style="list-style-type: none"> Improvement of the "Why?" "When?" and "What?" of nursing care is a dynamic process that can lead to changes in how nursing care is provided.

to more complex tasks such as administering medications, monitoring for adverse effects, and preparing patients for surgery, EBP is intimately associated with all nursing standards of care and nursing procedures. Part of the reason that EBP is so important is that it assists nurses in examining the *why* behind existing processes and procedures, encouraging nurses to advocate for patients by asking questions such as the following:

- Is this the best practice method available to support positive patient outcomes?
- Is there evidence supporting an improvement?

With the abundance of research available today, nurses are challenged to continuously evaluate and change their nursing practices based on current evidence. At the same time, as healthcare team members, nurses face the challenge of cost containment in managing care. Factors that influence decisions about potential interventions include availability of resources and requirements regarding reimbursement for services as stipulated by payment sources. Nurses must use best evidence related to finance and economics to develop a cost-conscious nursing practice (see the module on Managing Care for additional information).

Patients' participation in decisions about care is based on their individual influences and preferences, including health beliefs, culture, spirituality, and traditions (see the modules on Culture and Diversity and Spirituality for more information). For example, patients can agree to a treatment such as supplemental oxygen, refuse a treatment such as a blood transfusion, ask for a second opinion from a specialist

physician, and establish advance directives to ensure that they will be treated according to their preferences. Patients also may choose to incorporate integrative medicine into the plan of care (see Focus on Integrative Health). Many patients have access to resources that provide them with medical knowledge and clinical information through technology, including television and the internet, which can increase awareness of their condition and possible care options. Patients need to be a part of the process, and their preferences should be taken into consideration in clinical decisions about their care (see the module on Clinical Decision Making for further information). The Concepts Related to Evidence-based Practice feature outlines some, but not all, of the concepts that are integral to EBP. They are listed in alphabetical order.

Nursing Clinical Research

Nurses actively collaborate with other healthcare disciplines to provide high-quality patient care. They help patients navigate the healthcare environment and assume many roles, such as provider of care, advocate, teacher, and researcher (refer to the module on Accountability for additional information). Nurses help to ensure open and effective communication and continuity among all members of the healthcare team and patients and their families. Nurses who are actively involved in EBP access and use evidence from a variety of sources and disciplines to help guide their clinical practice and improve patient care. By using EBP, nurses also ensure the credibility of their profession and provide accountability for nursing care (**Box 45-2** >>).

Focus on Integrative Health

The Evidence for Integrative Medicine

As explained by the Academy of Integrative Health and Medicine (AIHM, n.d.), the term *alternative medicine* was replaced by *complementary and alternative medicine (CAM)*. CAM embodied the various philosophical approaches to healing that extended beyond conventional treatments and could be used either independently or in addition to traditional medical care (AIHM, n.d.). More recently, the term *integrative medicine* has replaced CAM. Integrative medicine combines the principles of CAM with conventional medical approaches. Integrative medicine, which emphasizes interprofessional collaboration among members of the healthcare team, has been successfully used in the treatment of individuals with a wide variety of conditions, including chronic pain, gastrointestinal disorders, stress, depression, and anxiety (AIHM, n.d.). Primary goals of integrative medicine include establishing best practices for promoting health and healing by way of combining evidence-based therapies with holistic approaches to healthcare (AIHM, n.d.). A study of 29 integrative medicine centers and programs across the United States found that integrative lifestyle change programs are particularly beneficial for individuals who experience chronic illness (Horrigan et al., 2012). Likewise, for individuals with depression, research has indicated that integrative interventions, such as hypnotherapy and meditation, are of benefit (Horrigan et al., 2012). Furthermore, research evidence suggests that integrative prevention strategies such as eliminating toxins from home and work environments and regular exercise are beneficial to all individuals (Horrigan et al., 2012).

Because evidence is a product of research, being familiar with the research process helps nurses to select and evaluate practices for best patient outcomes. In a very broad definition, *research* is obtaining information and objective facts to advance knowledge about a specific topic. **Nursing research** is the use of a systematic and strict scientific process to analyze phenomena of interest to all areas of nursing, including practice, education, and administration (Nieswiadomy, 2012). **Nursing clinical research** seeks answers to questions that will ultimately improve patient care, such as the following:

- What are the links between diet and the development of diabetes and cardiovascular disease?
- Is a new drug or medical device more effective than one already on the market?
- Do patients who undergo surgery at one medical center have a higher complication rate than those who are treated at another?
- Are patients satisfied with their care during hospitalization?

Familiarity with research methodology is becoming increasingly important to nursing practice. The ability to weigh the scientific merit of a research study is key to understanding the interpretation and implications of the research findings. Not all research findings have equal validity. One factor that influences the validity of a research study is the type of methodology that is used. The various methodologies used in clinical research include quantitative research and qualitative research.

Quantitative research uses precise measurement to collect data and analyze it statistically for a summary and a description of the resulting findings or to test relationships among variables. An example of a quantitative question is “Are there differences in skin breakdown between premature infants who are bathed with plain water and those who are bathed with bacteriostatic soap?”

Qualitative research investigates a question through narrative data that explores the subjective experiences of human beings and can provide nursing with a better understanding of the patient’s perspective. Goals of qualitative research include the identification of patterns and themes. An example of a qualitative question is “What is the nature of coping and adjustment after a radical mastectomy?”

Today’s nurses have a wealth of nursing research available that uses the scientific method to obtain evidence (**Box 45-3** ►). Using this method limits subjective

Box 45-2

An Example of Using EBP to Inform Practice

Traditionally, the hypoxic drive theory has held that patients with chronically elevated blood carbon dioxide levels, such as occurs with chronic obstructive pulmonary disease (COPD), may experience respiratory failure if exposed to high levels of supplemental oxygen. The hypoxic drive theory is based on the premise that, for individuals with an abnormally high level of carbon dioxide in the blood (a condition known as hypercarbia), a high level of carbon dioxide in the air no longer serves as a stimulus for breathing. Rather, according to this theory, when chronic hypercarbia is present, the stimulus for breathing is a low level of oxygen in the air (hypoxia), and administering supplemental oxygen to a patient with chronic hypercarbia may cause respiratory depression and respiratory failure (Jerath et al., 2015).

Despite research suggesting that patients with chronic hypercarbia generally do not depend on hypoxia as a stimulus for breathing (Kim et al., 2008), the hypoxic drive theory continues to influence clinical practice (Makic et al., 2013). However, Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines, which are based on current evidence, recommend supplemental oxygen administration for patients who demonstrate a PaO_2 of ≤ 55 mmHg and an oxygen saturation of $\leq 88\%$, with or without the presence of hypercarbia that has been confirmed twice in a period of 3 weeks (GOLD, 2015).

Box 45-3

General Elements of the Scientific Method

- A question is asked about a phenomenon.
- A literature review is done to identify past research findings on the phenomenon.
- A hypothesis is proposed.
- A study, or experiment, is planned and executed.
- Data are collected, organized, and evaluated.
- A conclusion about the phenomenon is presented.

influences and bias and enhances the validity and reliability of the data.

Funding

Funding from many sources is available to nurses who are interested in doing research to advance nursing science and generate evidence that supports improved patient care (American Nurses Association [ANA], n.d.). This funding ranges from small research grants from local professional nursing chapters to larger grants awarded by state or national nursing organization foundations. Corporations, state agencies, and federal organizations also support nursing research grants. Awards are given in all areas of nursing, including gerontology, quality of life, health disparities, disease prevention, and nursing practice specialties. Examples of sources of awards and grants are Sigma Theta Tau International Honor Society of Nursing, Agency for Healthcare Research and Quality, National Institute of Nursing Research, National Council of State Boards of Nursing, Robert Wood Johnson Foundation, and the American Cancer Society.

Participants

All research studies require participants. Because each study targets a specific population (e.g., women older than 65 years with a history of hypertension), researchers develop a list of criteria, which normally includes factors such as age, weight, gender, medical history, type and present stage of a disease, and present medications taken. These qualifiers can be categorized as inclusion (acceptable) or exclusion (not acceptable) criteria. Inclusion and exclusion criteria are used to guide selection of participants that represent the target population while also ensuring protection of potential participants' physical safety and psychosocial well-being. Vulnerable populations that are subject to strict legal and ethical considerations include human fetuses, neonates, children, prisoners, educationally disadvantaged individuals, and individuals who are cognitively impaired (U.S. Department of Health and Human Services [HHS], 2016a). Even for individuals who are legally capable of consenting to participation in a research study, in some cases, safety concerns may prohibit participating. For example, particularly with medication-related research, individuals with certain medical diagnoses may be excluded from participating because of potential health risks. **Research participants** are defined as volunteers for a specific study project who meet all the inclusion criteria, have been informed of all aspects of the study, and have given informed consent.

Ethical and Legal Issues

Ethical principles used by nurses to protect patients receiving care are also used to protect participants in clinical research studies (see the module on Ethics for further information). Ethical principles are at the core of such questions as "Did the researchers maintain the participants' confidentiality?" and "Did the participants experience physical harm or psychologic distress as a result of participating in the study?" **Institutional review boards (IRBs)** review research protocols and ensure that such protocols adhere to ethical standards. As established by the 1979 landmark publication *The Belmont Report*, research must adhere to three main ethical principles: respect for persons, beneficence, and justice (HHS, 2016b).
